† See foot-note with Table XXVI.

To Determine the Strength of an Existing Floor. When a buildi is leased for mercantile or manufacturing purposes the tenant will genera desire to know the greatest load which it will be safe to put upon the floo and some building laws require that the safe load for the floors in certain clas of buildings shall be computed and posted in a conspicuous place in each sto It is therefore important that every architect should know how to compute safe strength of any existing floor. The problem is practically the reverse that of proportioning a floor to a given load. In speaking of the strength o floor a distinction should be made between the safe strength and the safe lo The SAFE STRENGTH should mean the maximum safe load for the beams, inclu ing the weight of the construction, flooring and ceiling, while the SAFE LO refers to the maximum load which may safely be placed upon the floor. T safe load is found by first computing the safe strength and then subtracti the weight of the materials forming the floor, including the ceiling below, if th is one. The most convenient measurement for either the SAFE STRENGTH the SAFE LOAD of a floor is in pounds per square foot. The following examp will serve to show the method of determining the safe load for an ordinary wa house-floor.

Example 4. It is required to determine the safe load per square foot fo floor framed as shown in Fig. 4, the building being in a city the laws of wh

allow 1 200 lb per sq in for the safe flexure fiber-stress for the wood of which the joists and girders are made. The joists are covered with two thicknesses of ⅞-in flooring and the ceiling below is corrugated iron.

Solution. The first step will be to find the SAFE STRENGTH of the 22-ft joists. As this is a warehouse-floor we will use the tables for strength throughout. From Table XII, page 643, for $S = 1\ 200$ lb per sq in, we find the safe strength of a 1 by 14-in joist of 22-ft span to be 1 188 lb; hence the strength of a 2½ by 14-in joist will be $1\ 188 \times 2½ = 2\ 970$ lb. As the joists are 16 in on centers, each joist supports a floor-area of $1⅓ \times 22$ ft $= 29⅓$ sq ft. The SAFE STRENGTH PER SQUARE FOOT of this portion of the floor will therefore

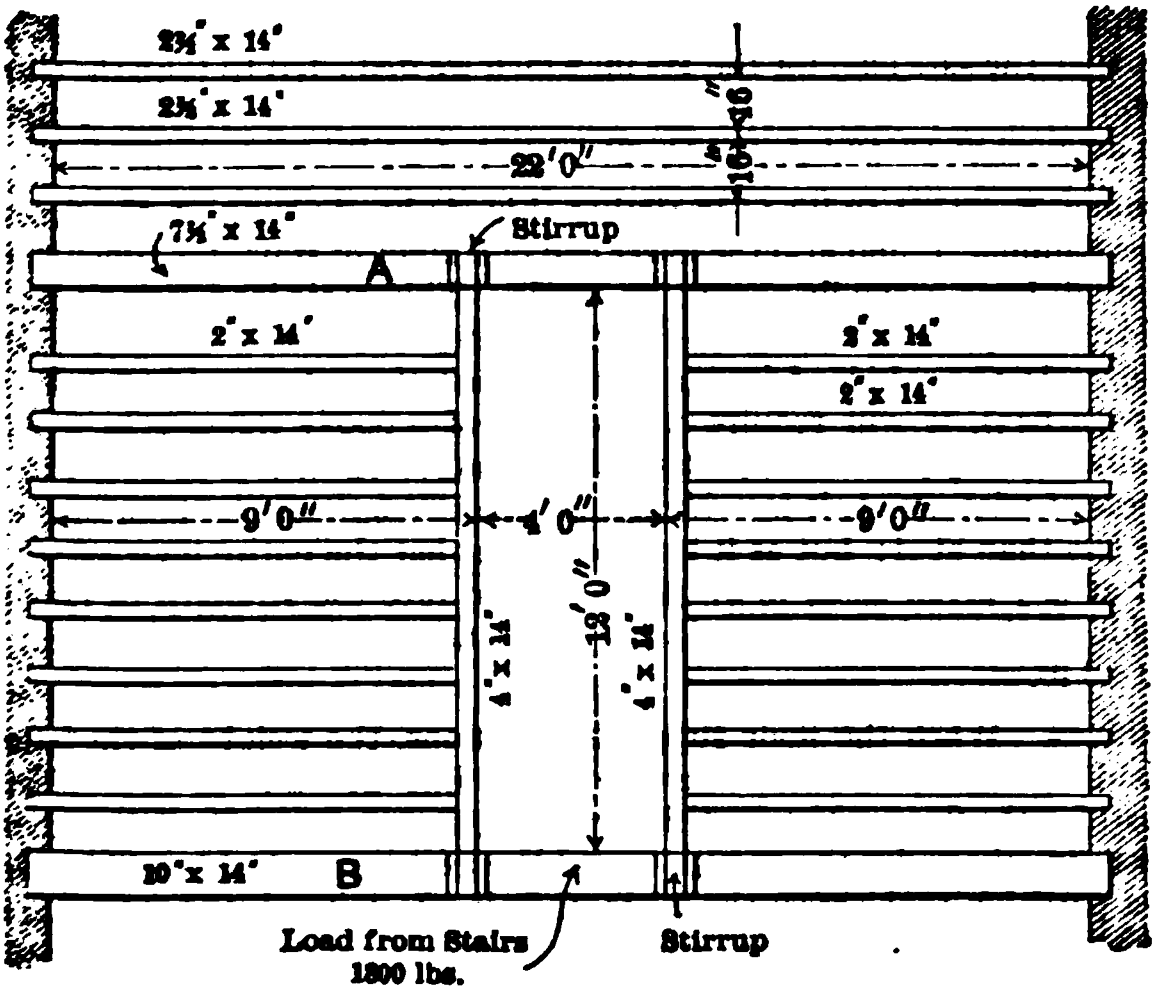

Fig. 4. Plan of a Warehouse-floor

be $2\ 970/29.3 = 101$ lb. Suppose the estimated weight of the floor per square foot is 8 lb for the joists, 6 lb for the flooring and 1 lb for the corrugated-iron ceiling, or, say, 15 lb in all. Then the SAFE LOAD PER SQUARE FOOT for the 22-ft joists will be $101 - 15 = 86$ lb.

The Headers. We will next find the safe load for the 4 by 14-in headers at each side of the stair-well. As the tail-beams are framed into the headers, we should deduct one inch from the thickness of each header for the loss of strength in framing, leaving 3 by 14 in for the effective dimension of each. From Table XII, page 643, we find the safe strength of a 1 by 14-in beam of 12-ft span to be 1 867 lb. Hence the strength of the 3 by 14 will be $1\ 867 \times 3 = 5\ 601$ lb. The floor-area supported by each header is $4½ \times 12$ ft $= 54$ sq ft; hence the SAFE STRENGTH of the header per square foot of floor is $5\ 601/54 = 104$ lb. Deducting the weight of the floor per square foot, we have $104 - 15 = 89$ lb for the SAFE LOAD.

Trimmer A. Trimmer A (Fig. 4) supports about the same amount of floor-area as one of the common joists, and supports, also, the ends of the headers. Deducting 2½ in, the thickness of the common joists, we have a 5 by 14-in beam

left to support the headers. As the headers are supported in iron stirrups, beam-hangers, no deduction in strength need be made for framing. To find t safe strength of a beam loaded with two concentrated loads, equidistant fr the supports, we must use Formula (14), Fig. 11, page 631. In this case a 8 ft 10 in, or $8\frac{5}{6}$ ft and $A = 1\,200/18 = 66.7$ (Table XII, page 643).

Applying the formula, the safe load at each joint $= 5 \times 14 \times 14 \times 66.7/4$ $8\frac{5}{6} = 1\,848$ lb.

The floor-area supported by one stirrup is equal to one-half of the area su ported by the header, or 27 sq ft; hence the safe strength per square foot the 5 by 14-in header is $1\,848/27 = 68$ lb, and deducting 15 lb per sq ft the weight of the floor, we have 53 lb per sq ft as the safe load that the trimm will support on the floor at each side of the stairs. Considering, as fou above, that the safe load for the $2\frac{1}{2}$ in, which we deducted to take the place o common joist, is 86 lb per sq ft, we might consider the safe load for the trimm as the average of 86 and 53, or about 70 lb per sq ft.

Trimmer B. This 10 by 14-in timber (Fig. 4) has to support the same flo loads as trimmer A, and also the lower end of a flight of stairs for which an allo ance of at least 1 800 lb should be made. This stair-load being practica concentrated at the middle of the trimmer is equivalent to a distributed load 3 600 lb. As the safe load for a 1 by 14-in joist of 22-ft span is 1 188 lb (Tal XII, page 643), it will require a thickness of $3\,600/1\,188 = 3$ in to supp the stairs, leaving 7 in to support the floor-loads. As this is $\frac{1}{2}$ in less than t thickness of trimmer A, it is evident that the strength of the floor at B will a little less than at A; but as it is improbable that the entire floor-space will loaded at any given time, it would be safe to rate the strength of the floor each side of the stairway at 70 lb per sq ft, LIVE LOAD, and beyond the sta way at 86 lb.

Partitions. When the floor supports partitions, the weight of the latter a any load resting upon them must be taken into account in determining t safe load for the floor. If a partition runs the same way as the joists, then o the joist directly under the partition, and the joists at each side will be affect but if a partition runs across the joists, then it affects the safe load of the ent floor.

Example 5. Suppose that the 22-ft joists in the floor shown in Fig. 4 have support a plastered partition 12 ft high, running across the joists half-way b tween the walls. What will be the safe load for the floor?

Solution. A plastered partition with 2 by 4 or 2 by 6-in studs, set 16 in centers, weighs about 20 lb per sq ft of partition-face; hence a partition 12 high will weigh 240 lb per lin ft of partition. As the joists are 16 in on c ters, each joist supports $1\frac{1}{3}$ lin ft of partition, weighing 320 lb. As this load concentrated at the middle span of the joists it is equivalent to a distribut load of 640 lb. In Example 4, we found the safe distributed load for the $2\frac{1}{2}$ 14-in joists of 22-ft span to be 2 970 lb. Subtracting 640 lb from this we h 2 330 lb, which may be used for the floor. As the floor-area supported by e joist is $29\frac{1}{3}$ sq ft, the safe strength of the floor per square foot is $2\,330/29\frac{1}{3} =$ lb, and the safe load is $79 - 15 = 64$ lb per sq ft. Hence the partition decrea the safe load by $86 - 64 = 22$ lb per sq ft. Whenever the upper-floor joi are supported by a partition carried by a floor below, the effect of the partiti and its load upon the strength of the lower floor should be very carefully co puted.

Bridging of Floor-Joists. By BRIDGING is meant a system of bracing floor-joists, either by means of small struts, as in Fig. 5, or by means of sin

[...]es of boards set at right-angles to the joists and fitting in between them. [...]e effect of this bracing is of decided advantage in sustaining any CONCEN-[...]ATED LOAD upon a floor; but it does not materially strengthen a floor to resist [...] UNIFORMLY DISTRIBUTED LOAD. The [...]dging also stiffens the joists, and pre-[...]nts them from turning sidewise. It is [...]tomary to insert rows of cross-bridging [...]m 5 to 8 ft apart; and to be effective [...]e rows of bridging should be in straight [...]es along the floor, so that each bridging-[...]ut may abut directly opposite those [...]acent to it. The method of bridging [...]wn in Fig. 5, and known as CROSS-[...]DGING, is considered to be by far the [...]st, as it allows the thrust to act [...]allel to the axis of the strut, and not [...]oss the grain, as must be the case [...]ere single pieces of boards are used. [...]e bridging should be of 1¼ by 3-in [...]ck, for 2 by 10-in and smaller joists, [...]d of 2 by 3-in stock for 12- and 14-in [...]sts.

Fig. 5. Floor-joists with Bridging

[...]raming of Wooden Floor-Beams. [...] dwellings, tenements and lodging-[...]ses it is frequently necessary to frame the timbers so that they are flush [...]h one another. The old methods of framing the tail-beams and headers or [...]ders and trimmers by mortise-and-tenon joints are now generally superseded [...] hanging the timbers in stirrups or malleable-iron joist-hangers. In this construction the entire strength of the timbers is retained, while the cost of the hangers is often less than the labor-cost in preparing the mortise-and-tenon joints. All headers 6 ft or more in length should be carried in joist-hangers or stirrups and this is usually required in the building codes of the large cities. In warehouses and all first-class buildings the framing should be done by means of joist-hangers. For light floors, with moderate spans, it is generally safe to frame the tail-beams into a header, provided the latter is strong enough to carry the load and allow 1 in in thickness for the mortising. Headers, [...], carrying not more than two tail-beams are often framed into the trimmers. [...] case the old methods of framing are used instead of the superior methods [...]h joist-hangers, the best shape and proportions for the tenons and ends of [...] tail-beams or headers are those shown in Fig. 6. This form of framing

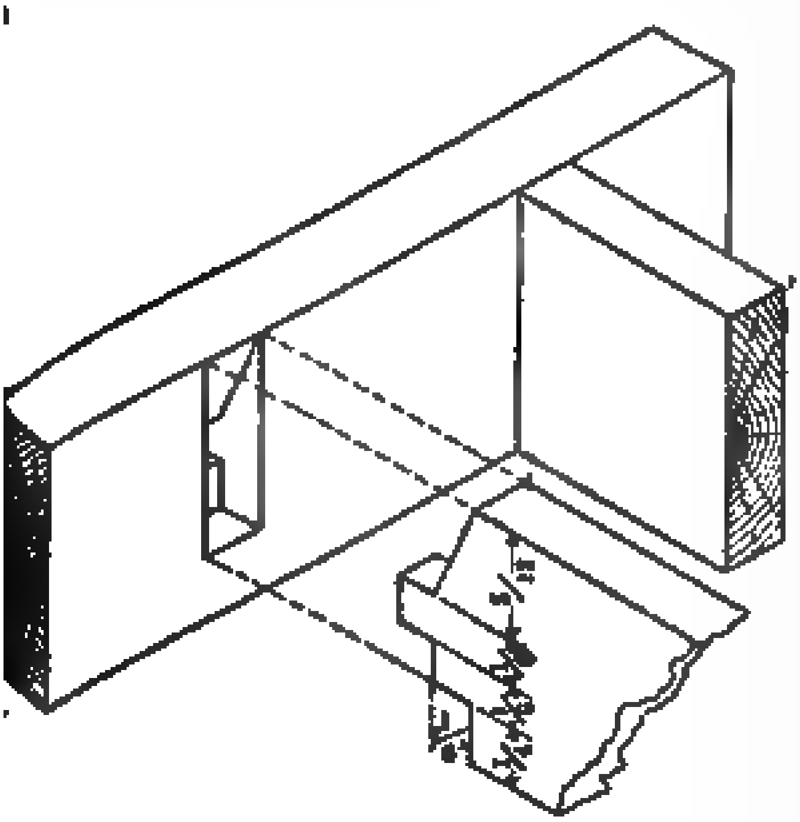

Fig. 6. Framing of Joists into Header

probably offers as large a proportion of the strength of the timbers as it possible to utilize, although for tail-beams it was the opinion of Mr. Kidd that a single tenon like that shown in Fig. 7 is fully as strong, especially wh the header is built up of 2-in planks spiked together. In either case, if the flo

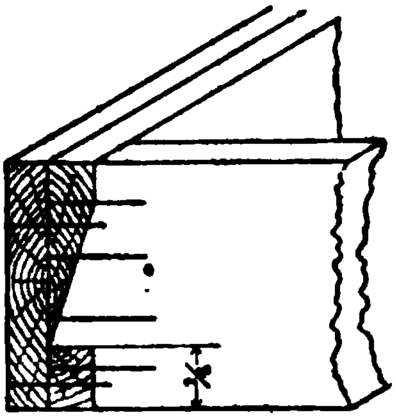

Fig. 7. Alternate Method of Framing Joists into Header

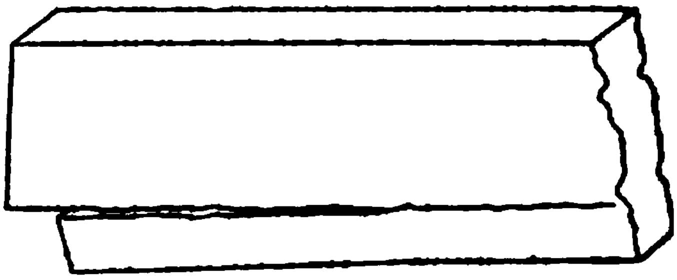

Fig. 8. Framed Joist Split by Load

is loaded to its full strength, the tail-beam will split at the bottom of t tenon, as shown in Fig. 8, which illustrates the weakening effect of t mortise-and-tenon framing.

Stirrups and Joist-Hangers. The first device used for framing headers trimmers without mortising was the wrought-iron stirrup shown in Fig. These are made either single or double, depending upon whether one or t beams are to be supported. To prevent the floor from spreading and thus p

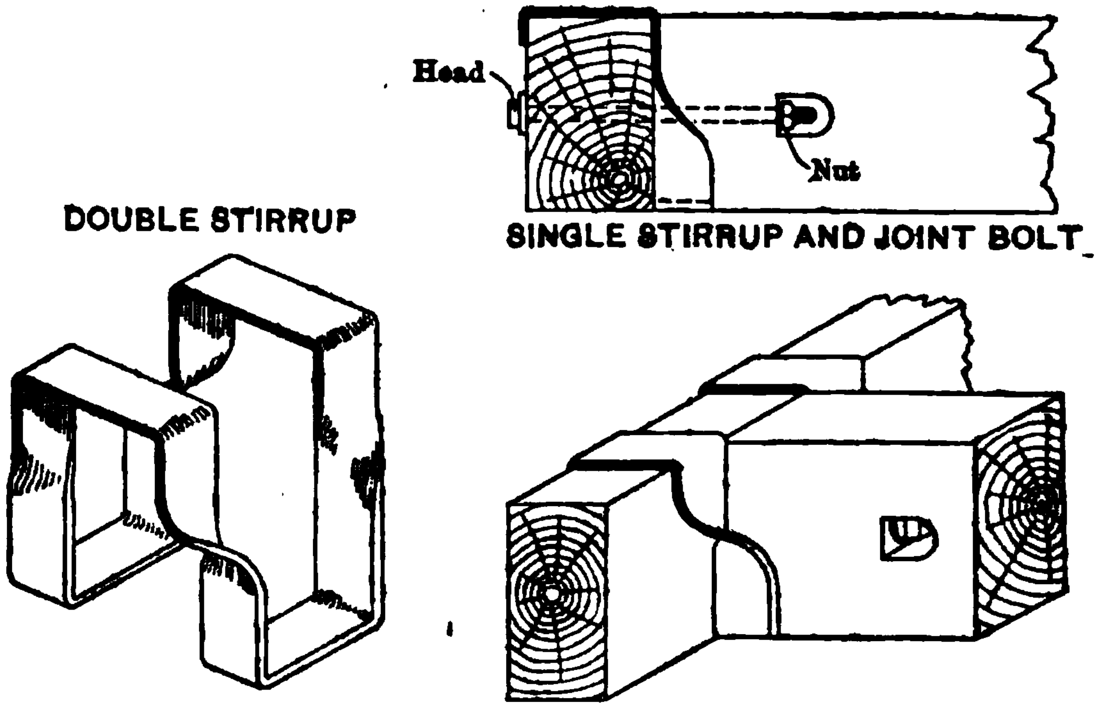

Fig. 9. Framing with Wrought-iron Stirrups

mitting the header to slip out of the stirrup, a joint-bolt may be inserted, shown in the two right-hand illustrations of Fig. 9. To determine the stren of a stirrup, multiply the sectional area of the iron, in square inches, by 12 lb per sq in. (Table 1, page 376.)

The following sizes of iron should, in general, be used for the different s of joists to be supported:

of joists or timbers to be supported, in inches	Sections of stirrup-iron in inches
2 by 8 to 3 by 10	¼ by 2¼
4 by 10 to 4 by 12	⅜ by 2½
6 by 12 to 3 by 14	⅜ by 3
8 by 12 to 4 by 14	½ by 3½
6 by 14	½ by 4
8 by 14 to 10 by 14	⅝ by 4

Joist-Hangers. Aside from the matter of strength there are objections to e use of stirrups. If the timber on which they rest is not perfectly dry, the irrups will settle by an amount equal to the shrinkage of the beam on which they t, and let down the header with them, and the projection of the iron above e top of the timbers will necessitate cutting out the flooring. If the stirrups e exposed in this way their appearance is objectionable. While they may designed to resist any tensional stress the resistance of steel to bending comparatively small, and the resulting crushing of the timber where they over the edge is the chief objection to the use of stirrups of this type heavily loaded floors. The small bearing of a timber on a stirrup is

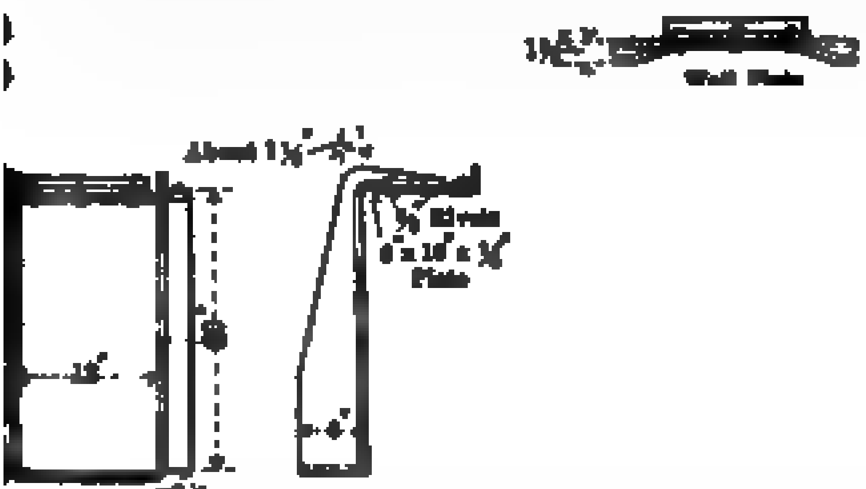

Fig. 10. Failure of Steel Stirrup Wall-hanger

sufficient to distribute the load on the wood over the required area. This eases the bearing per square inch, allows the hanger to crush into the edge tends to straighten out the stirrup as shown in Fig. 29, page 757. The e serious objection applies to the use of steel stirrup-hangers in brick walls arry beams free of the walls. As previously explained, all the load is ught to the extreme edge, causing a much greater load per square inch on masonry than is allowable. Fig. 10 * shows the effect of crushing, in a house-building in Minneapolis, Minn. Wall-hangers made of steel ps should not be used. Patented steel hangers riveted to bearing-plates likewise very undesirable as the crushing effect is greatest at the outer , due to the straightening-out tendency of the hanger at this point.

gs. 11 and 12 illustrate the Duplex and Goetz joist-hangers, which are nted and are claimed to be superior to the old-style stirrups. The Duplex er is used not only for ordinary building-construction, but for the most ily loaded mill-construction in factories and warehouses. As these hangers ade of malleable iron they will not straighten out when heated, in case of and drop the beams. That is what happens to wrought-steel stirrups

Taken from a paper on "Joist and Wall-Hangers," read by Mr. F. E. Kidder at a g of the Colorado Chapter of the American Institute of Architects, February 27,

when the twist becomes heated. This hanger has proven perfectly satisfact and is extensively used. Both are made in sizes to fit all regular sizes of joi or girders, and have ample strength for the purpose for which they are intend

Fig. 11. Duplex Joist-hanger

Fig. 12. Goetz Joist-hanger

As shown by the illustrations, they are made to be inserted in round holes bo in the side of the carrying timbers, at or a little above the center line. W these hangers the effect of shrinkage is reduced one-half, and the other two

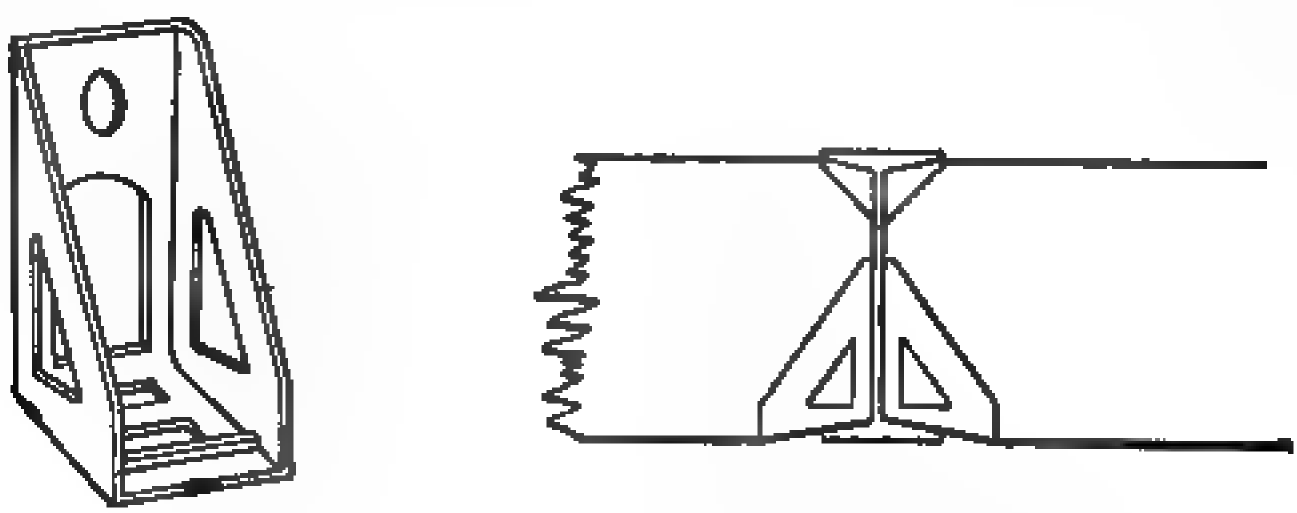

Fig. 13. Duplex I-beam Hangers

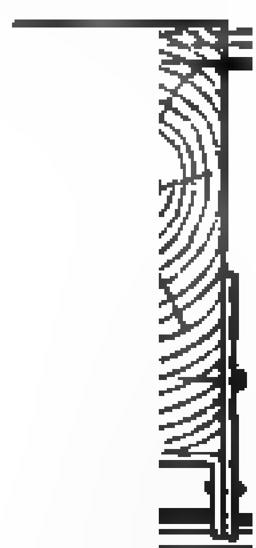

Fig. 14. Duplex I-beam Shelf-hanger. Joists Raised Less than Four Inches

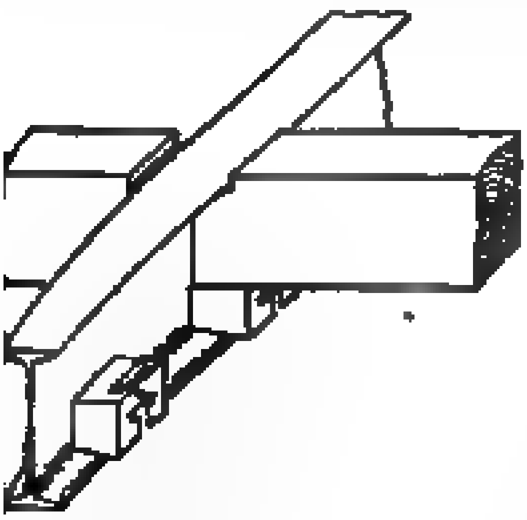
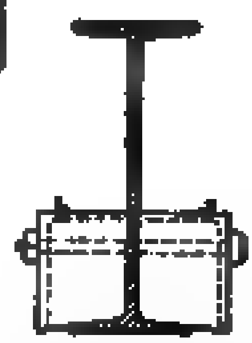
jections to the stirrup, previously mentioned, are overcome. The Du hanger has ridges on the inside of the side brackets to hold the beam.

For timbers of larger size and for the heaviest construction, the Duplex hang

wn in Fig. 32, page 789, are used and are bolted to the beams. By this struction the entire building is tied together laterally.

Fig. 13 shows the Duplex I-beam hanger for framing floor-joists to I beams. is hanger is made to exactly fit into the flange of the I beam. It has a rib





. 15. Duplex I-beam Box Hanger. Joists Raised More than Four Inches

Fig. 16. Duplex Wall-hanger for Joists

the bottom, ¾ in high, which serves as a tie when the joist is placed in the ger, and it provides a bearing of at least 4½ in for the joist. It is made carry any joist of regular size, and offers one of the best devices for framing oden joists to I beams of the same th. The hangers are bolted to the b of the I beam. Fig. 14 shows the plex I-beam shelf-hanger which is used en the construction requires the joists be raised above the lower flange of the am less than 4 in. Fig. 15 illustrates Duplex I-beam box-hanger and is mmended where the joists are raised re than 4 in above the lower flange the I beam. In both these construc- s the hangers are bolted singly or posite, as required, on the I beam and loads are carried on the lower flanges of the beams. Fig. 16 shows a ilar hanger made to support the wall-end of a floor-joist. This form of struction is considered much superior to the method of building the

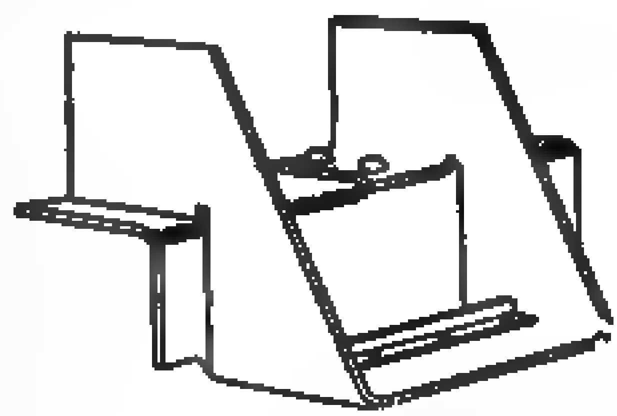


Fig. 17. Duplex Steel Wall-hanger for Large Beams

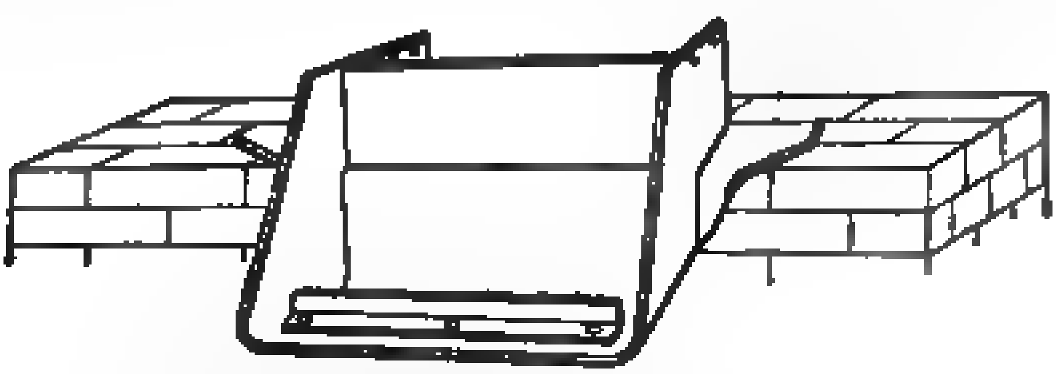

Fig. 18. Duplex Extra-heavy Wall-hanger for Mill-construction

ts into a wall, as it absolutely prevents dry-rot, and permits the joists to in case of fire, without throwing the wall. It also gives the load a good ing on the wall. Fig. 17 illustrates the Duplex steel wall-hanger for larger ms, and Fig. 18 shows the Duplex extra-heavy wall-hanger for the heaviest

mill-construction. These hangers bear the label of approval of the Natio Board of Fire Underwriters and are generally considered the best-designed w hangers now on the market. This hanger gives an extra bearing on the maso and is so constructed that it reacts as a unit and distributes the load equally o the entire surface of the masonry. There is no tendency for a hanger of t

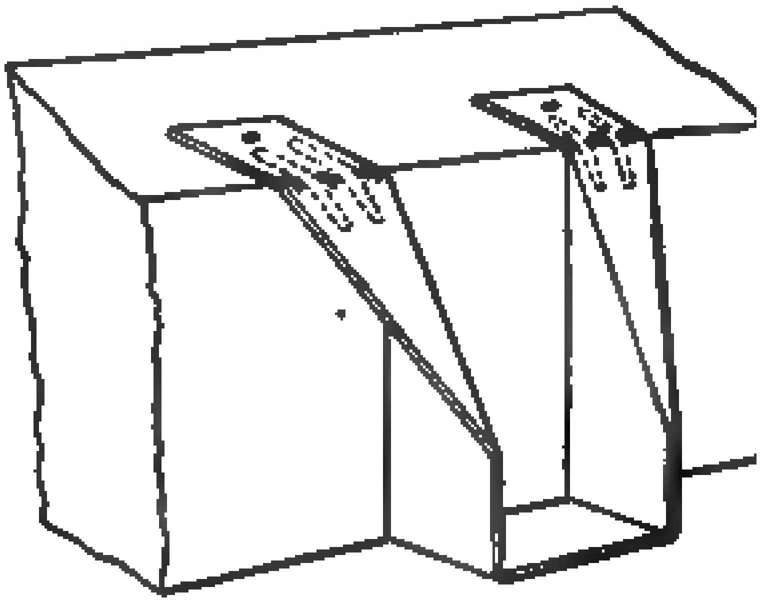

Fig. 19. Duplex Wall-hanger for Concrete Blocks

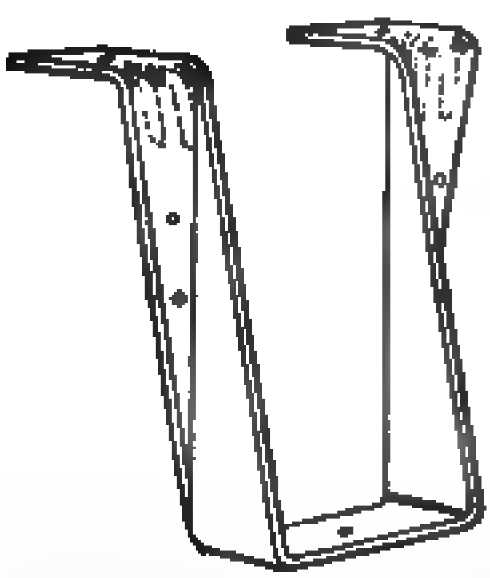
Fig. 20. "Ideal" Wrought-steel Beam-han

type to crush in at the edge of the masonry and straighten out, as is the c with some other types of wall-hangers. Fig. 19 shows the Duplex wall-han used in connection with walls constructed of concrete blocks. These hangers often used in repair-work in party walls, as they avoid the cutting of large h in the walls, and also provide an easy and simple method of carrying the jo clear of the walls. The Ideal hanger illustrated in Fig. 20 is made of wrou



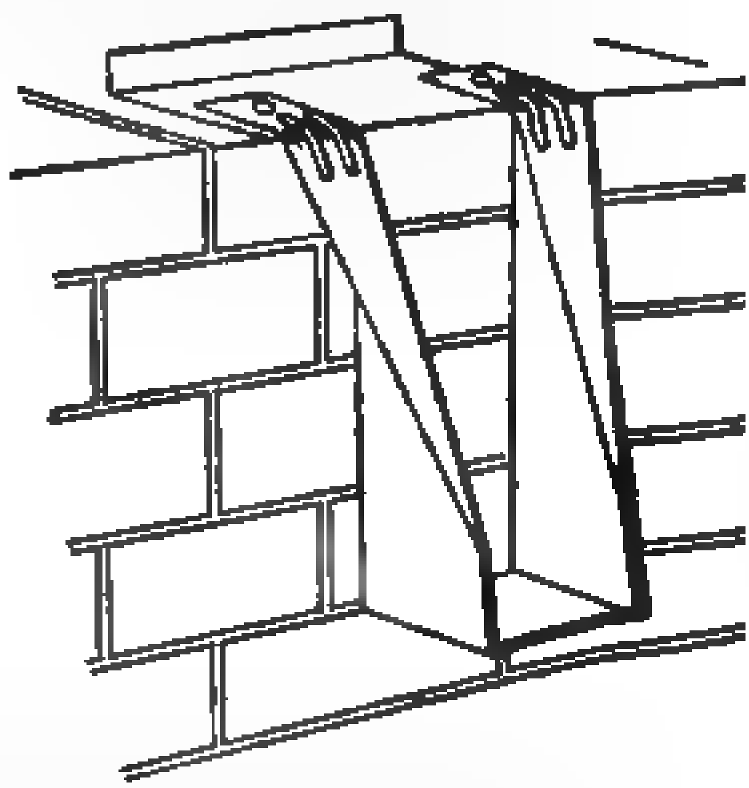


Fig. 21. "Ideal" Wrought-steel Beam-hanger

Fig. 22. "Ideal" Wrought-steel Wall-han

steel and corrugated at the points where it is bent over. This reinforces it tends to prevent bending at these points. Fig. 21 illustrates another for the Ideal hanger with holes for spiking to a timber. This hanger, als corrugated. In these hangers the full strength of the steel is retained as fibers of the metal are not cut in forming them. They are made of wrou steel bars folded to the required shape. Fig. 22 shows the Ideal hanger giv

a steel plate and in position to be built into a brick wall. Other illustrations wall-hangers are given in Chapter XXII. The Van Dorn hanger, illustrated Fig. 23, is essentially a stirrup forged from high-grade steel. The few tests it have been made would seem to indicate that it developes a greater re- ance to bending than the ordinary stirrup, while it gives a wider bearing

.23. Van Dorn Beam-hanger

Fig. 24. Van Dorn Wall-hanger

the joist and presents a much neater appearance. Fig. 24 shows the same er riveted to a bent iron plate, to build into brick walls. When the hanger o be used over a steel beam the upper ends are bent to fit over the flange of beam, as in Fig. 25. "Although I know of no test of the strength of a Van n I-beam hanger, it would seem as though it must be much stronger than

Comparative Strengths Different Types of Jo Hangers. Although the t
that have been made to de
mine the strength of diffe
hangers are few in number
sufficient number have b
made to show that any one
the hangers described, includ
the common stirrup, is ab
dantly strong for any SIM
FLOOR-BEAM not exceeding 4
14 in in cross-section. It
only in the case of a header
trimmer which supports a load over a considerable floor-area that the stren
need be considered at all. From tests
and on girder-hangers, it would appe
hangers usually develop great streng
by 14-in girder, sustained a load of
itself. A similar hanger held until
loaded up to 39 550 lb, when one
side broke off short under the
nipple projecting into the timber,
the condition of the hanger after
failure being shown in Fig. 28. A
common stirrup made from ⅝ by
2½-in wrought iron failed under a
load of 13 750 lb by bending and
pulling over the header, as shown
in Fig. 29. A 6 by 12-in steel
hanger "began to straighten out
under a load of 13 300 lb, and failed
to hold under a load of 18 750
lb."* SINGLE hangers of the
stirrup-type DO NOT BREAK, but fail
by the bending up of the parts
which lie over the top of the header

Fig. 28. Result of Test of a Two-p
Beam-hanger

as shown in Fig. 29. They also appear to crush the wood under them
ticularly at the edges, to a very much greater extent than does the spoo
the Duplex hanger. With a DOUBLE stirrup the ultimate strength is meas
by the strength of the iron. Thus, a double stirrup, made of ⅝ by 2¼-in wro
iron, was loaded up to 57 650 lb (28 825 lb on each side), when it broke at
of the lower corners. A single stirrup would of course be just as strong
could be kept from bending. In actual construction the flooring over the be
to some extent prevents the top of a stirrup from springing up. The tests

* From data compiled by Mr. Kidder from a series of tests on beam-han
and joist-hangers.

been made of two-part hangers show conclusively that where only a e hanger is used the holes h are bored in the header do seriously affect its strength the load is within the safe , and a test made at Balti- , Md., August 24, 1904, with 12-in joists, spaced 12 in on rs and suspended by these rs let into a header formed ree 3 by 12-in joists, spiked her, would seem to prove even when the holes are 12 in they do not seriously weaken The only record of the fail- f any form of hanger when tual use in a building, of I am aware, is that of a e in Minneapolis, where a n of six floors of a ware- fall, on Nov. 7, 1902, through ilure of a wall-hanger made a 4 by 2 by ¼-in structural- angle, which was sheared and bent, and riveted to an 8 by 16 by ¼-in g-plate. The failure was due to the crushing of the outer edge of the ork under the hanger, and the consequent bending up of the top portion. ctual load on the hanger was about 15 000 lb." *

CHAPTER XXII

WOODEN MILL AND WAREHOUSE-CONSTRUCTIO

By

A. P. STRADLING

SUPERINTENDENT OF SURVEYS, PHILADELPHIA FIRE UNDERWRITERS' ASSOCIATION

1. Mill-Construction

Definition. The term MILL-CONSTRUCTION is commonly used to design method of construction brought about largely through the influence of Boston Manufacturers' Mutual Fire Insurance Company of Boston, Mass., especially through the efforts of Mr. Wm. B. Whiting, whose judgment mechanical matters, and experience and skill as a manufacturer were for m years devoted to the interests of insurance companies, and to the improvem of factories of all kinds. The extended use of this system and the improvem that have been made in it during recent years are probably due more to influence of Mr. Edward Atkinson, President of the Boston Manufactu Mutual Insurance Company and Director of the Insurance Engineering Exp ment Station at Boston, than to that of any other individual.

Cost. The purpose of mill-construction is to reduce the fire-risk to its l est point without going to the expense of fire-proof construction. The increa cost of heavy timber, however, and in fact of all lumber, together with lessened cost of the erection of the so-called FIRE-PROOF TYPES, constru entirely of reinforced concrete, or built with protected steel frames and inc bustible floors, and the recognition, also, of the obvious advantages of n FIRE-RESISTING CONSTRUCTION, especially in the congested sections of cities, bringing these types into more general use. The cost of these latter type construction is, in many instances, no more than the cost of various type mill-construction.

The Slow-burning or Mill-Construction Type. The experience of y has entirely justified the use of this type. It renders possible a somewhat costly, and at the same time, what is of great importance, a more effective sys of fire-protection than can be installed in buildings of light construction, the so-called JOISTED FLOORS and with the roofs made of boards supporte 2-in, 3-in, or 4-in joists. The entire subject of SLOW-BURNING or MILL-C STRUCTION as applied to factories is most admirably described and illustr in Report No. 5 of the Insurance Engineering Station of the Boston Ma facturers' Insurance Company, No. 31 Milk Street, Boston, Mass., from w the author has, by permission, taken and adapted many of the following i trations and descriptions.

2. What Mill-Construction Is*

(1) **Heavy Timbers.** MILL-CONSTRUCTION consists in so disposing timbers and planks in heavy, solid masses as to expose the least numb corners or ignitable projections to fire; and to the end, also, that when occurs it may be most readily reached by water from sprinklers or hose.

* From Report No. 5 of the Insurance Engineering Station of the Boston Man turers' Insurance Company, No. 31 Milk Street, Boston, Mass.

(2) **Fire-Stops.** It consists in separating every floor from every other bor by incombustible STOPS, by installing automatically closing hatchways nd by encasing stairways either in brick or other incombustible partitions, so hat a fire will be retarded in passing from floor to floor to the utmost consistent ith the use of wood or any material not absolutely fire-proof.

(3) **Fire-Retardants.** It consists in guarding the ceilings over all specially azardous stock or processes with FIRE-RETARDANT MATERIALS, such as plastering laid over wire lath or expanded metal, or over wooden dovetailed lath, llowing the lines of the ceilings and of the timbers and leaving no interspaces etween the plastering and the wood; or else in protecting the ceilings over azardous places with asbestos, air-cell boards, sheet metal, Sackett Plaster oard, or other fire-retardant.

(4) **Fire-Safeguards.** It consists not only in so constructing the mill, workhop, or warehouse that fire will pass as slowly as possible from one part of the ilding to another, but also in providing all suitable SAFEGUARDS AGAINST FIRE.

2. What Mill-Construction Is Not

(1) **Concealed Spaces.** Mill-construction does not consist in so disposing a en quantity of materials that the whole interior of a building becomes a SERIES WOODEN CELLS, or concealed spaces, connected with each other directly or cracks through which fire may freely pass where it cannot be reached by ater.

(2) **Size of Timbers, Fire-Stops, etc.** It does not consist of an open-timber struction of floors and roofs which resembles mill-construction, but which built with light timber of insufficient size and with thin planks, without fireps or fire-guards from floor to floor.

(3) **Stairways.** It does not consist in connecting floor with floor by COMSTIBLE WOODEN STAIRWAYS encased in wood less than two inches thick.

(4) **Partitions.** It does not consist in putting in very numerous LIGHT, OODEN DIVISIONS or partitions.

(5) **Sheathing and Furring.** It does not consist in SHEATHING brick walls ith wood, especially when the wood is set off from the walls by FURRING, and en if there are stops behind the furring.

(6) **Varnish.** It does not consist in permitting the use of VARNISH on woodrk over which a fire will pass rapidly.

(7) **Glass, Fire-Shutters and Wire-Glass.** It does not consist in leaving ndows exposed to adjacent buildings and unguarded by FIRE-SHUTTERS or RE-GLASS.

(8) **Painting and Dry-Rot.** It does not consist in painting, varnishing, ng or encasing heavy timbers and thick planks, as they are customarily livered, and thus making possible what is called DRY-ROT, caused by a lack ventilation or opportunity to season.

(9) **Sprinklers, Pumps, Pipes, Hydrants, etc.** It does not consist in ring even the best-constructed building in which dangerous occupations are lowed without AUTOMATIC SPRINKLERS, and without a complete and adequate ipment of PUMPS, PIPES and HYDRANTS.

(10) **Finishing in Wood and Other Materials.** It does not consist in ng more WOOD IN FINISHING a building after the floors and roof are laid than bsolutely necessary, since there are now many safe methods available at low t for finishing walls and constructing partitions with slow-burning or in-

combustible materials. Accordingly if plaster is to be put on a ceiling and to follow the line of the underside of the flooring and the flooring-timbers, should be PLAIN LIME-MORTAR PLASTER, which is sufficiently porous to pen seasoning. The addition of a skim-coat of lime-putty is hazardous, especi if the overflooring is laid over rosin-sized or asphalt paper. This rule app to almost all timber as now delivered. Examples of all of the faulty meth of construction above mentioned have been found in various buildings p porting to be of mill-construction, and they all form parts of what has so times been called COMBUSTIBLE CONSTRUCTION.

4. Standard Mill-Construction

Example of Standard Mill-Construction. Fig. 1 shows a cross-sect through a mill of the customary or STANDARD TYPE recommended by the Bos Manufacturers' Mutual Insurance Company, the details of construction be revised to May, 1908.

Walls. If additional stories are required, the walls may be increased thickness according to the number of stories added, after a computation been made of the loads which a STANDARD FACTORY may be called upon to s tain. Walls should be of brick and at least 13 in thick in the upper story, their thickness should be increased in the lower stories to support additio loads. Plastered walls are often to be preferred to unplastered walls. Wind arches and door-arches should be of brick, and window-sills, outside door-sills under-pinning of granite or concrete.

Roofs and Floors. The roofs should be of 3-in pine planks spiked dire to the heavy roof-timbers, and covered with five-ply tar-and-gravel roofi Roofs should incline from ½ to ¾ in per ft, and incombustible cornices recommended when there is exposure from neighboring buildings. Fl should be of spruce planks, 4 in or more in thickness according to the fl loads, spiked directly to the floor-timbers, and kept at least ½ in away from face of the brick walls. In order to obviate the danger of cracking the wa which sometimes results from the swelling of planks laid close against th these spaces left between walls and floor-planks must be covered by strip battens both above and below. In floors and roofs, the bays should be fr 8 to 10½ ft wide, and all planks two bays in length should be laid to br joints every 4 ft, and grooved for hard-wood splines. Usually an overfloo birch or maple is laid at right-angles to the planking, but the best mills hav double overfloor, a lower one of soft wood, laid diagonally upon the planks an upper one laid lengthwise. This latter method allows boards in alleys passageways to be easily replaced when worn, while the diagonal boards br the floors, reduce the vibration, and distribute the floor-loads more unifor than the former method. Between the planking and the overfloor should two or three layers of heavy, hard paper, laid to break joints, and each mop with hot tar or similar material to make a reasonably water-tight as wel dust-tight floor. The usually rapid decay of the basement or lower floor mills makes it desirable, whenever wood is not absolutely necessary, to m such floors of cement. If wooden floors are required, crushed stone, cind or furnace slag should be spread evenly over the surface, and covered wit thick layer of hot-tar concrete. On this tarred felt is often laid, well mop with hot-tar asphalt, and over it a flooring of 2-in seasoned planks, well pres down and nailed on edge without perforating the water-proofing under it. hard-wood boards of the overfloor are then nailed across the planks. Cem concretes promote decay of wood in contact with them. If extra supports required for heavy machinery, independent foundations of masonry should

Fig. 1. Modern Mill-building of the Standard Type

provided. In view of the difficulties frequently met with in preserving ba ment floors of the ordinary timber construction, because of the lack of suital ventilation underneath, and also in view of the rapid decay of timber and pla floors in bleacheries, dye-works, print-works, and the like, in which the flo quickly become saturated with moisture, artificial-stone floors are being l in many of the modern plants.

Sizes and Kinds of Timbers. All woodwork, not STANDARD CONSTRU TION, in order to be SLOW-BURNING, must be in LARGE MASSES which present t least surface possible to a fire. No pieces less than 6 in in width should be u for the lightest roofs, and for substantial roofs and floors much wider ones a needed Timbers should be of sound, long-leaf, yellow pine, and for sizes to 14 by 16 in, single pieces are preferred, or, timbers 7 to 8 by 16 in, are oft used in pairs bolted together, without air-spaces between. They should n be painted, varnished or filled for three years because of the danger of dry r and for the same reason, an air-space should be left in the masonry around t ends.

Beam-Boxes, Column-Caps, etc. Timbers should rest on CAST-IR PLATES or BEAM-BOXES in the walls and on cast-iron caps on the columns. BEA BOXES are of value as they strengthen the walls when the floor loads are hea and the distance between windows small; they facilitate the laying of t bricks and the handling of the beams; and there is less danger of breaking t bricks in putting the beams in place. They also insure proper air-spaces arou

Fig. 2. Floor-timber on Wall-plate

Fig. 3. Roof-timber on Wall-plate

the ends of the beams. Fig 2 shows a floor-timber resting on a CAST-IRON WA PLATE with a lug for anchoring the timber to the wall. Fig. 3 shows a ro timber resting on a CAST-IRON WALL-PLATE, an overhanging, open, wood cornice and a wrought-iron joist-anchor. Fig. 4 shows a CAST-IRON CAP a PINTLE for columns, and dogs for holding the floor-timbers together. Fig. shows a roof-timber resting on a COLUMN-CAP cast to fit the slope of the ro the timbers are held together by 1-in wrought-iron dogs. These diagrams a intended only as general illustrations of SLOW-BURNING or MILL-CONSTRUCTI The details should always be adapted to the special conditions of the site a to the purposes for which the buildings are used.

Columns of yellow pine should be bored through the axis, making a 1½- diameter hole, and should have ½-in lateral vent-holes near the top and botto The ends should be carefully squared. To prevent dry-rot, WOODEN COLUM

uld not be painted until they are thoroughly seasoned. They should be set pintles which may be cast in one piece with the cap, or separately. Cast-iron columns are preferred by some engineers, and when a building is equipped th automatic sprinklers, such columns have proved satisfactory; but they

Fig. 4. Post-cap and Pintle for Floor-timber and Columns

Fig. 5. Roof-timbers on Column-cap

not as fire-resisting as wooden columns. Wrought-iron or steel columns uld not be used unless encased with at least 3 in of fireproofing.

Windows should be placed as high and made as wide as possible to obtain the atest amount of light, and the use of ribbed glass is recommended for the per sashes.

Weight, Deflection and Vibration. In computing the size of the timbers ratio to the working-load, consideration must be given not only to the weights ich are to be carried, but also to the character of the machinery which is be operated on the floors. Beams of sufficient strength to support the weights y vibrate or deflect under the weight and action of the machinery; and there , therefore, three factors, weight, deflection and vibration, which must considered in determining the width and depth of the beams that are to used in the structure.

Objectionable Types of Construction. "We do not approve what has n sometimes miscalled mill-construction, that is, longitudinal girders ting upon posts and supporting floor-beams spaced 4 ft, more or less, on ters. This mode of construction not only adds to the quantity of wood d, but the disposal of the timbers obstructs the action of the sprinklers, prents the sweeping of a hose-stream from one side of the mill to the other, and girders also obstruct the most important light, that from the top of the ndows."

Timber, Ventilation, Painting, etc. Timbers, unless known to be thorghly seasoned, should not be encased in any kind of air-proof plastering nor nted with oil-paints; white-wash, calcimine and water-paints may be used, they are porous. As a rule, timbers should be left unprotected, since a which will seriously impair and destroy heavy timbers will already have its work upon other parts of the structure.

Single and Compound Beams. While, in general, single beams should be d, in some instances it may be desirable to substitute compound beams, de by fastening two or more beams or thick planks side by side. It is often er to obtain well-seasoned lumber in small dimensions. Such compound ms should be tightly bolted together without air-spaces, and owing to the ger of dry-rot, should not be painted or varnished for three years.

Steam-Pipes. If a mill is to be heated by conveying steam through pi such pipes should be hung overhead.

Cornices. Wherever buildings are exposed or are liable to be exposed fire in the near future, the cornices should be of non-combustible construction preferably, the walls should extend above the roof-timbers.

Glass, Frames and Shutters. All openings in walls should be protec either by approved wire-glass in approved, metal frames or by standard f shutters.

5. Belts, Stairways and Elevator-Towers

Continuous Floors. One of the most important features of SLOW-BURN CONSTRUCTION is to make each and every floor CONTINUOUS from wall to w

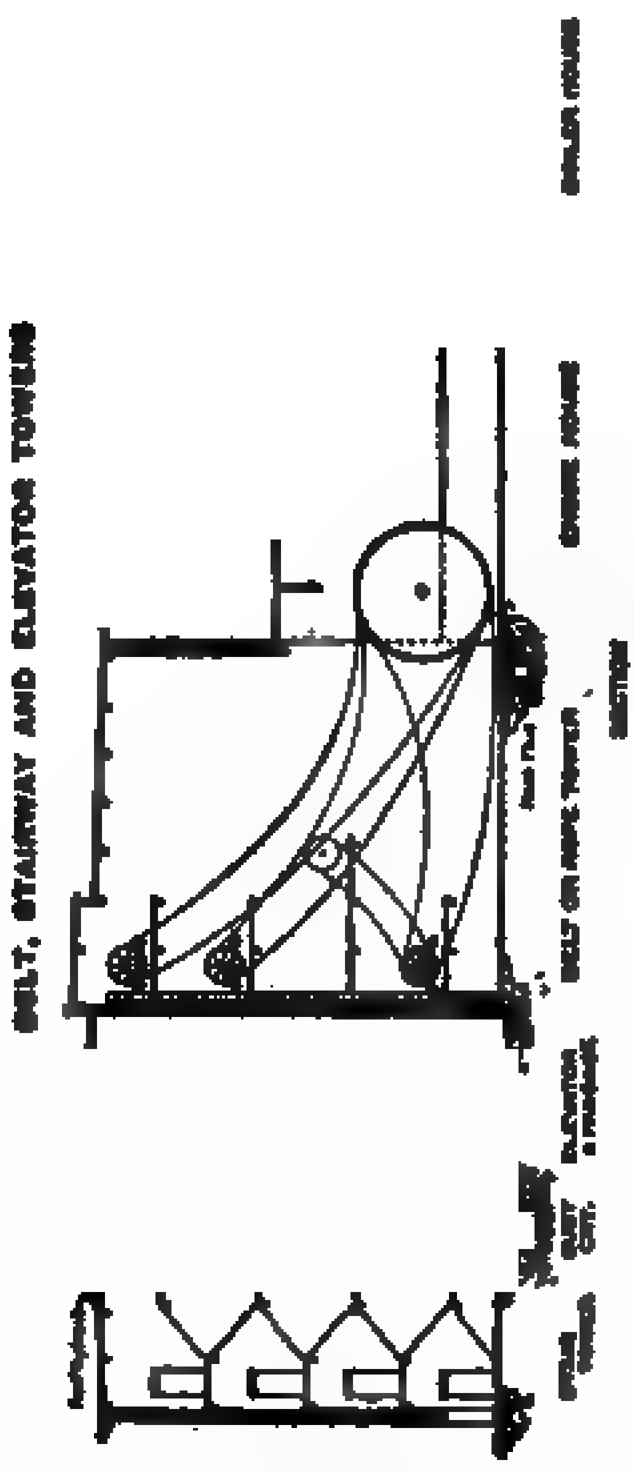

Fig. 4. Section through Tower for Elevators, Stairs and Belts

avoiding, as far as possible, holes for bel fire may be confined to the story in whi owner, engineer or builder will, therefore main belts, in BRICK TOWERS or in sections

y incombustible walls. All openings in these walls should be protected by STANDARD FIRE-DOORS, preferably self-closing. In modern practice all belts and ropes which may be used for the transmission of power to the various rooms, be placed in INCOMBUSTIBLE VERTICAL BELT-CHAMBERS, from which the power transmitted by shafts through the walls into the several rooms of the factory. here should be no unprotected openings in the inner walls of this BELT-HAMBER.

Shafts above Roof. Skylights. All SHAFTS for STAIRS, ELEVATORS, ELTS, etc., should extend at least 36 in above the roof, and all such shafts ould be, if possible, on the outside of the building. Elevator and belt-shafts ould be covered with thin glass skylights in metal frames, protected underneath with wire netting. Figs. 6 and 7 illustrate a section and plan of a COTTON-LL, showing elevator, stair and belt-shafts arranged on the above principle. LOSETS should be in a separate tower rather than in manufacturing rooms.

The Boiler-Plant should be in a separate building cut off from the engine-om by a brick wall, and the openings in this wall should be protected by AUTO-TIC, SLIDING, STANDARD FIRE-DOORS.

6. Standard Storehouse-Construction

xample of Storehouse-Construction. Fig. 8 shows a cross-section through fire-tower and Fig. 9 the first-story plan, including the elevator and stair-er of a four-story ehouse.

rea. Buildings this purpose ld not, in gen-, exceed 5 000 sq in AREA. When d, however, for ge of non-haz-us goods, the may be in-sed to 10 000 sq

Fig. 8. Four-story Storehouse. Section through Fire-tower

ight of Stories. storehouses, the s should be made low enough (Fig. 10) to prevent overloading, and when ed for case-goods, the HEIGHT OF STORIES should be sufficient to take two , with a 12-in. clear space under the beams to allow for the distribution of r from the sprinklers.

-Walls. For convenience, as well as to separate the different hazards of aterials and finished goods, the building should be divided into sections E-WALLS extending at least 36 in above the roof.

-Story Storehouses. A ONE-STORY STOREHOUSE is recommended in ce to the design just described, whenever there is a sufficient quantity l land at disposal for this purpose. The one-story building is cheaper, convenient, and, when separated into small divisions by fire-walls, repre-he safest method of storehouse-construction.

bers and Framing. The FLOOR-TIMBERS and ROOF-TIMBERS should be -leaf yellow pine, in single pieces, if possible. If necessary to use double , they should be bolted together without air-spaces between them. Tim-

bers should rest on cast-iron plates or beam-boxes in the walls, and on cast-ir caps on the columns. At least ½-in air-spaces should be left around all bea built into the masonry, allowing free ventilation and preventing dry rot. Co

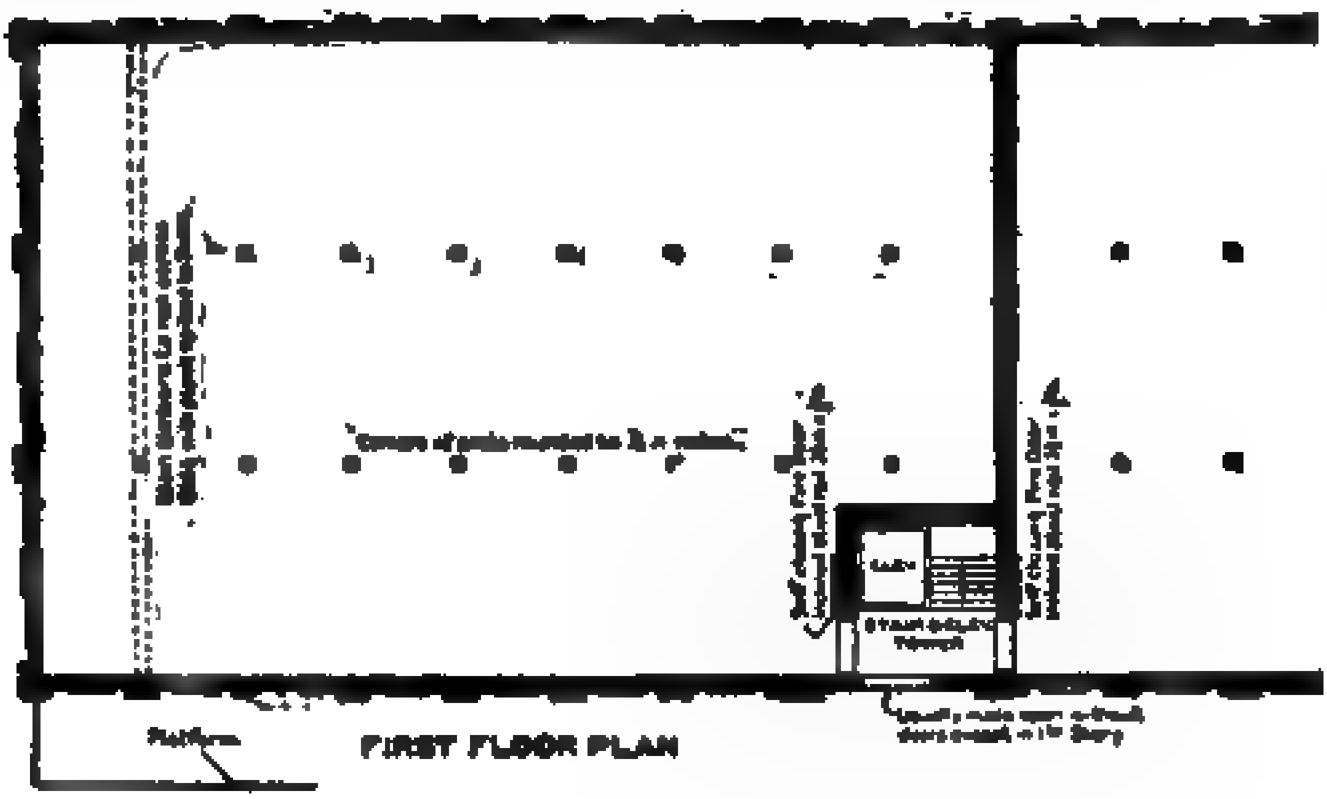

Fig. 9. Four-story Storehouse. First-story Plan

umns of yellow pine should have their end-surfaces cut square with the colum axis.

Floors. The FLOORS of such buildings should be continuous, without op ings, and of the standard slow-burning construction, described under STAND

Fig. 10. Four-story Storehouse. Isometric View

MILL-CONSTRUCTION. The flooring should be constructed as called for u STANDARD MILL-CONSTRUCTION. In order that the floors may be as ne water-proof as possible, tarred paper, mopped with tar, should be applie previously suggested. The floors in each story of the tower should be at l 1 in lower than the floor in the adjoining compartment, and the sills of the d openings to the tower should be inclined to make up the difference in le The sill, also, of the outside door of the tower should be lower than the to floor.

Scuppers. Water on the floors of the tower will ordinarily flow down the tower-stairs, and the arrangement of the floor-levels indicated above will ordinarily prevent water from an upper story from flowing into one of the lower compartments, if it is escaping through the tower. Cast-iron SCUPPERS are advised, and they should be set in the brickwork at frequent intervals, and so designed that they will carry away rapidly a maximum quantity of water from the floors of each compartment. To further the drainage of water, the floors should be inclined from the middle of the compartments to the scuppers. Fig. 11 shows the WIND-SHIELD SCUPPER* which embodies the latest improvements.

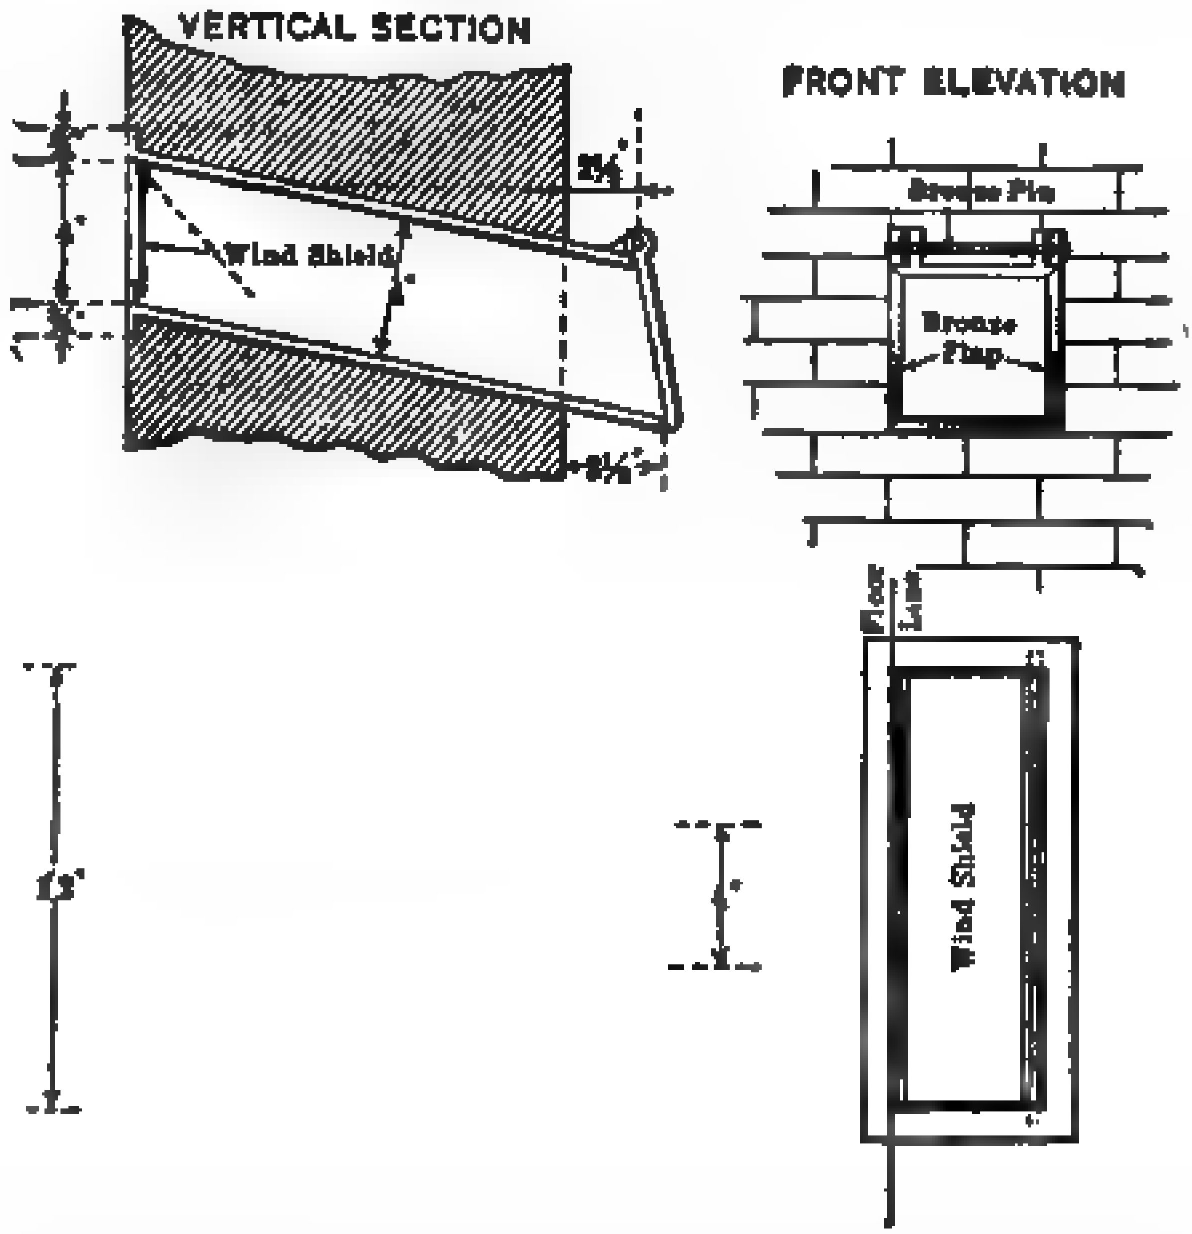

Fig. 11. Detail of Wind-shield Scupper

In the old-style scupper only one flap is provided on the outside of the building. During winter and windy weather, this flap blows open and sometimes freezes open. This results in a continuous draft through the scupper and over the working floor of the factory or warehouse and necessitates an increase in the amount of heat furnished. The scupper shown in Fig. 11 corrects this condition by providing the light wind-shield on the floor-level of the scupper. When the outer flap blows open the wind-shield shuts off the draft from the outside. The scupper, in addition, acts as a fire-retardant when an adjoining building is burning, and when there is a tendency for the flames to communicate through the open scupper and ignite merchandise on the floor. The wind-shield, by shutting off the drafts and fire, acts as a retardant or shield to keep out the flames.

* Manufactured by the Wind-Shield Scupper Company, 1 Madison Avenue, New York City.

Tower for Stairways, Elevators, etc. Access to the various stories obtained by means of a BRICK TOWER outside the main building, extending 36 above the roof, and containing STAIRWAYS, ELEVATORS, ETC., access to which

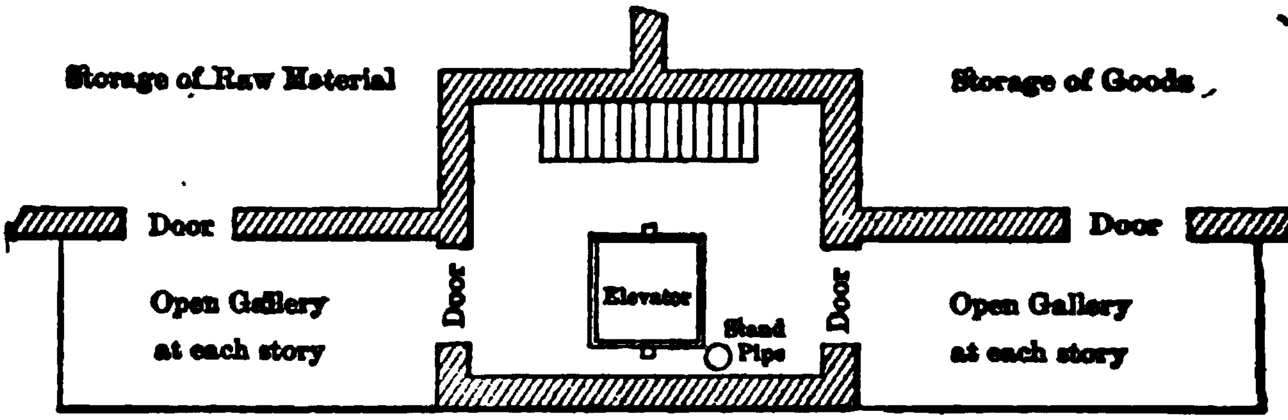

Fig. 12. Stairway-tower and Galleries at Side of Storehouse

obtained by open galleries at each floor-level. (See Fig. 12.) A door from the upper story of the tower affords a ready means of reaching the r AUTOMATIC HATCHES are not necessary for the elevator, as GUARD-GATES s every purpose. If it is necessary to construct the tower for the elevator stairs inside of the building, access to it should be as shown in Fig. 13. T

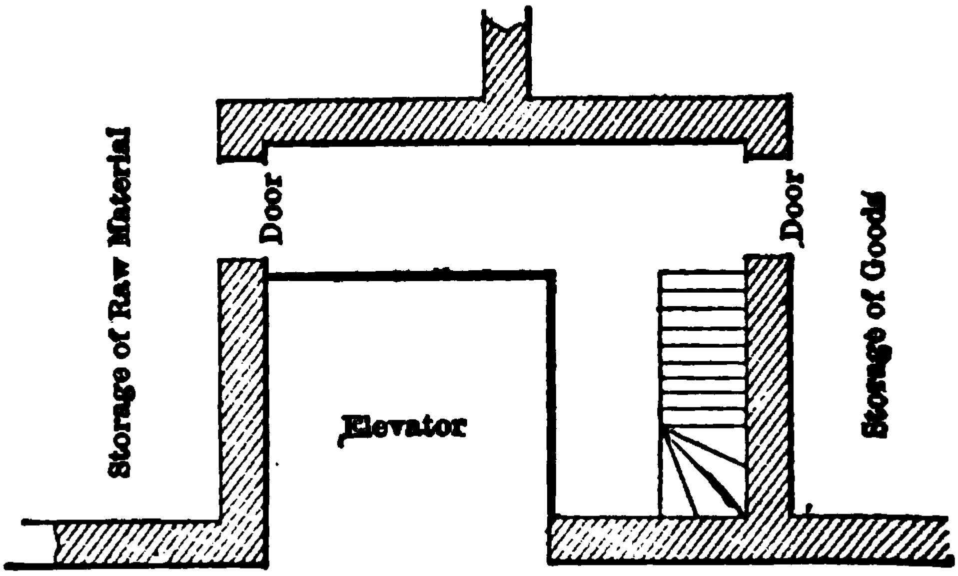

Fig. 13. Stairway-tower Inside of Storehouse

construction serves, also, as a FIRE-TOWER, part of the outside wall omitted.

Roof Walls and Parapets. The WALLS should extend 36 in above the and the PARAPET should be laid in cement, because the moisture readily sorbed by the bricks would otherwise pass downward and make the walls top story damp. In some instances a course of bricks dipped in coal-t laid above the roof-level.

Sprinklers, Standpipes and Hose. Mills and storehouses should be tected throughout by AUTOMATIC SPRINKLERS and by inside STANDPIPE HOSE-EQUIPMENTS. Dry-pipe sprinklers should never be used unless it practicable to heat the building. These systems should be planned and vised by a thoroughly reliable fire-protection engineer. (See, also, Ch XXIII, pages 903 to 905.)

7. Example of One-Story Work-Shop

conomy. For work-shops on cheap, level land, and especially for buildings which the stock is heavy, ONE-STORY BUILDINGS have proved to be more nomical than higher buildings, in cost of floor-area, supervision, moving ck in process of manufacture and repairs to machinery, much of which be run at greater speeds than when it is in high buildings.

Warming and Ventilating. Window-Area. Such buildings are readily med and ventilated, and heavy-plank roofs are free from condensation in d weather. Window-areas should be as large as practicable, as a large window-a reduces the hours of artificial illumination. If the building is exposed to from another building or buildings of hazardous occupancy, the windows uld be of the Fenestra, Lupton or other equally good, steel construction, ed with wire-glass. The forced circulation of heated air is a very desirable thod of heating mills, and should be used in connection with overhead steam-es.

Floors. As wooden floors are subject to rot, the general floor-construction, possible, should be of concrete or earth or some other non-combustible mate-l. But as the dust rising from floors of such materials injures machinery, as the dripping of oils weakens such floors and seems to make a WOODEN ORING-SURFACE necessary, the following construction is recommended. ken slag or stone, several inches in thickness and thoroughly rolled, is first down, and over this a 4-in layer of tar-concrete. On this is laid a 1-in kness of asphalt, evenly rolled. Over this, 2 or 3-in hemlock planks, bedded hot pitch, are laid and over them a ⅞ or 1⅛-in maple floor, at right-angles the planks.

Column and Beam-Construction. Figs. 14 and 15 show clearly the mode COLUMN AND BEAM-CONSTRUCTION. No beams or other structural timbers uld be painted or varnished until thoroughly seasoned.

The Roofs should be as called for under STANDARD MILL-CONSTRUCTION. SSES in roofs are ordinarily from 8 to 20 ft on centers, the 3-in planks span-g the distance between the trusses as shown in Fig. 14, or resting on PURLINS less than 8 ft on centers, and running longitudinally, as in Fig. 15.

Cornices and Gutters. In Fig. 14, the overhanging OPEN CORNICE is wn, with a drip to the outside and without gutters. Roofs sloping back to de gutters, as shown in Fig. 15, are preferable. Projecting BRICK CORNICES, ch protect the woodwork from outside fires, are shown in Fig. 15. If the ding is exposed to other buildings of hazardous construction and occupancy, APETTED BRICK WALLS and cornices are needed.

oof-Construction. The roof-planks should be at least two bays in length, king joints every 3 ft; or, if purlins are used, the planks should cover at t two spaces between the purlins, and break joints as above. Roof-timbers uld be well anchored to walls in a safe and suitable manner. While the -TOOTH form of roof may be used with this type of building, it may be always necessary or advisable; and the types shown in Figs. 14 and are types common for machine-shops, foundries, and similar buildings, in ch increased head-room is required for traveling cranes. The middle sec-over the crane is often provided with SAW-TOOTH SKYLIGHTS with excellent ts, and the side bays and others are made higher for galleries.

eel Structural Members. In ordinary one-story machine-shops, or in ings of similar nature, where wide spans or trusses are necessary, the of STEEL STRUCTURAL MEMBERS is not objectionable.

Fig. 14. One-story Work-shop. Roof-boards on Trusses

Fig. 18. One-story Work-shop. Roof-boards on Purlins
with thoroughly mopped tarred felt under plank

8. Saw-Tooth Roof-Construction*

The Great Advantages and the increasing use of SAW-TOOTH roof-const tion, and the lack of familiarity with it at many factories, make it desirabl outline important features.

Two Typical Designs are illustrated, Fig. 16, a TEXTILE WEAVE-SHED a good basement for the shafting for driving the looms on the main floor ab thus dispensing with the overhead shafting and belting in the weave-ro and Fig. 17, a design for a light MACHINE-SHOP or FOUNDRY. Other desi using light wooden trusses or reinforced-concrete walls, are applicable.

Roof-Types. It may be well to state here that while light roofs with and 3-in joists and with light boards should never be used, and while the p ciples of SLOW-BURNING OR MILL-CONSTRUCTION, with its heavy timbers, preferred, the increasing difficulty of promptly obtaining yellow-pine lumbe good dimensions, and its increasing cost, often necessitate the use of tru and rather light timbers; but in no case should these timbers be less than in width nor of insufficient depth to carry the load. This, also, is in o that they may be SLOW-BURNING. The roofs in all cases should be constru of planks and have wide bays.

Steel Roof-Trusses. The adaptability of the light forms of STEEL FRAMING TRUSSES, especially when wide spans are needed, often compels t use; and in plants having a safe occupancy, such as that of metal-workers, trusses are not objectionable, providing adequate sprinkler-protection wi good water-supply is available to prevent quick failure of the steel work, to heat from the combustion of the contents of the building or from the bur of the roof. Similar protection is, of course, needed in shops with woo TRUSSES, if disastrous fires are to be prevented; but experience has shown the STEEL-TRUSSED ROOF will fail much more rapidly than one of wood u similar conditions.

Wooden versus Steel Columns. WOODEN POSTS are nearly always a able and should be given preference; but if light STEEL COLUMNS are nece they should be well protected by insulating materials if they are in rooms taining combustibles, as the column is the vital part of the roof-support.

Advantages of Saw-Tooth Roofs may be outlined as follows:

(1) **Uniform Diffusion of Light** throughout the room, thus makin space in it available. With all interior surfaces painted white and with ri glass in the sashes, the DIFFUSION OF LIGHT is almost perfect.

(2) **Better and Cheaper Lighting.** Greater adaptability for ligh large floor-areas in wide buildings with low head-room when compared what is necessary in wide buildings with the ordinary form of monitor-skyli Saw-tooth roofs furnish the true solution of the problem of excluding the d rays of the sun and obtaining the very desirable north light. They resu greater ECONOMY IN LIGHTING, as they lower the fixed charges due to the sm number of hours per day during which artificial light is necessary.

(3) **Better Working-Conditions,** especially in textile-mills, thereby inc ing production and encouraging permanency of employees.

(4) **Special Adaptability to many Industries.** The SAW-TOOTH for especially adapted to weaving and similar processes in textile-factories, to chine-shops, foundries doing light work, and similar processes, such as as

* Taken and adapted by permission from the Boston Manufacturers' Mutual I ance Company's specifications for the construction of saw-tooth roofs.

Fig. 18. Saw-tooth Roof for Textile Weave-shed

Fig. 17. Saw-tooth Roof for Machine-shop

ing and drafting, and to some dye-houses where careful matching of colors is necessary.

Disadvantages of Saw-Tooth Roofs. While the testimony of those who have had experience with SAW-TOOTH ROOFS is almost uniformly favorable, some difficulties have been experienced, practically all of which may be summed up as due to either faulty design or poor workmanship. The difficulties in general are caused by

(1) **Leaks,** due to severe conditions during winter in our northern climates.

(2) **Poor Ventilation.**

(3) **Excessive Heat** when roofs are thin.

(4) **Excessive Condensation** on the underside of roof and glass when the temperature outside is low and there is considerable moisture in the rooms.

Approved Methods of Construction. The following suggestions show how the difficulties mentioned may be obviated if the APPROVED METHODS are applied to special cases by competent engineers or architects. What is good ENGINEERING from the view-point of the manufacturer can also be good FIRE-PROTECTION ENGINEERING, and any design should be adapted to both if the best interests of the manufacturer are to be served:

(1) **Diffused Indirect Sunlight.** As it is desirable to avoid direct sunlight and at the same time obtain an abundance of light, perfectly diffused, the SAW-TEETH should face approximately north and the glass should be inclined to the vertical to take advantage of the brighter light in the upper sky and to prevent cutting off the light by the saw-tooth immediately in front; and, above all, to assure the DIFFUSION OF THE LIGHT over the floor rather than on the under side of the roof-planking.

(2) **Angle of Glass.** For the glass an angle of from 20° to 25° from the vertical and an angle of approximately 90° at the top of the SAW-TOOTH will be about right, the variations depending upon the amount of light required and the latitude. A sharper angle at the top is not needed, as it increases the cost, and makes more roof to be covered and larger spans; more glass, also, is required in proportion, and the light is not as good, as more light from the sky is lost and too much light is thrown on the under side of the roof.

(3) **Glazing-Details.** DOUBLE GLAZING with a space left between the lights of glass is preferred on account of its conducting qualities; but it is not always necessary, except in the more northerly countries. The inside glazing should be done with factory-ribbed glass, set with the ribs vertical and facing it. Shadows cast by trusses are then almost unnoticeable.

(4) **Gutters and Conductors.** CONDENSATION-GUTTERS are needed inside, at the bottom of the sashes, and they should be drained through INSIDE CONDUCTORS and not to the outside under the bottom of the sashes, as these latter admit cold air and are liable to freeze.

(5) **Valleys** between the SAW-TEETH should be flat, from 14 in to 2 ft in width and pitched ½ in per ft towards the conductors, which should be of ample size, and not much over 30 ft apart, and preferably less. The necessary PITCH may be obtained by cross-pieces of varying heights set on top of the trusses, and thus avoiding hollow spaces.

(6) **Prevention of Leaks.** LEAKS, which are common faults, may ordinarily be prevented by a careful design of the gutters, valleys and sashes, and by insisting on good workmanship and materials. The roof-covering of asphalt or pitch should be continuous through the valleys and extend up to the glass.

One form of construction understood to have been very satisfactory is shown Fig. 18 and in connection with it, reference should be made to the papers an discussion on SAW-TOOTH ROOFS in Trans. Am. Soc. M. E., 1907, vol. 28, whi contain much of value.

(7) **Warming and Ventilation.** Experience has demonstrated the adva tage of a combination of DIRECT RADIATION with a FAN sufficient only for VE TILATION and TEMPERING the heat of the room. Heating-pipes should usual be placed overhead and directly under the front of the SAW-TEETH, and run t entire length, and this position assist preventing condens tion. Where there no moving shaftin some forced circu tion is necessary, a it is best obtained a fan, which driv the air from either dry basement or fr outside as may required, and d charges it over hea ing-coils to the st above. In weav and similar roo this is especia necessary and adva tageous in promot the health and co fort of the employe and in making th working-efficien greater. Ventilation and cooling of these large areas with comparatively l stories must not be neglected. Ample vents are needed at the top in form of large metal ventilators with double walls and tight dampers. Th are recommended in place of pivoted or swinging sash, which are apt to l in driving storms, and when open, allow dirt to blow in from the r Good windows are advised in side walls and experience has shown their value

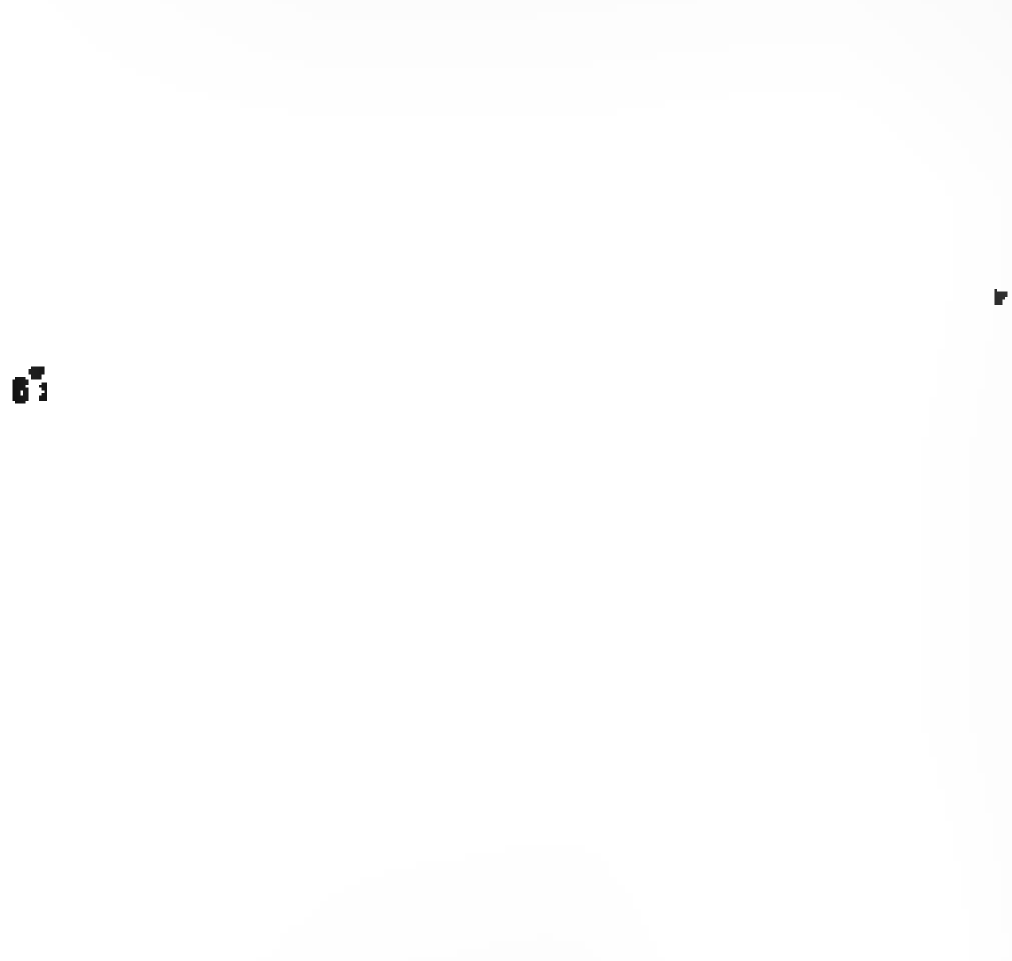

Fig. 18. Detail of Valley of Saw-tooth Roof

(8) **Details of Framing and Construction.** The FRAMING of the SA TEETH may be of timber, steel or reinforced concrete. The design should such as will obstruct the light as little as possible, strong enough to hold snow without sagging, and stiff enough to carry shafting motors, etc., wh they are to be overhead. When wood or steel is used the roof-plank should be 3 in or more in thickness spanning bays from 8 to 10 ft in wid HOLLOW SPACES in roofs should not be permitted. They are very unde able from a fire-standpoint, and any condensation which may take place them during cold weather soon rots both planks and sheathing. SHEATHI even without spaces behind it, is a more or less objectionable feature, as i readily combustible; but if it is used it should be applied directly to the un side of the roof-planks, with only a layer of some insulating material between that there will be no concealed spaces. If 3-in planks are sufficient for a roof, they should be, also, for a SAW-TOOTH roof; and with a good circula of air there should be no trouble, except in wet rooms. In such rooms ther

found to be condensation, whether they are under a roof or under the floor of a room above, unless large quantities of dry air are discharged into them.

(9) **Cost.** SAW-TOOTH ROOFS necessarily cost more than FLAT ROOFS, as there is practically the same amount of roofing as in flat roofs and, in addition, the cost of windows, glazing, flashing, conductors, condensation-gutters for skylights, and a somewhat larger cost for heating. The additional cost of these items does not, however, fairly represent the comparative cost, as there should be considered the total cost of the building compared with that of an ordinary one with sufficiently high stories and with a width narrow enough to give the required light. When this is done the slight additional cost is far outweighed by the advantages gained for work requiring very good light.

9. Mill-Construction as Applied to Warehouses

Cost. Owing to the increasing cost of heavy timbers for wooden construction, to the lower cost of the so-called FIRE-PROOF CONSTRUCTION, and also to the better FIRE-RESISTING qualities of the latter, owners, architects and builders should carefully compare the cost of construction, and also the cost of insurance of the two types, before deciding on the one to be used. The difference in the cost of construction between these two types is so small, that in many localities the lower cost will be in favor of the REINFORCED CONCRETE or other type of FIRE-PROOF CONSTRUCTION. The cost of construction is also in favor of the FIRE-PROOF TYPE, where both long spans and strength are required.

Timber-Spacing for Sprinklers. Warehouses of MILL-CONSTRUCTION should be built so as to allow the best possible distribution of water from AUTOMATIC SPRINKLERS, with the least possible obstructions, and floor-timbers, therefore, should be as few as the floor-loads will allow. There should be no concealed spaces of any kind in the building. To insure the greatest efficiency for sprinkler-systems, it is better to adapt the timber-spacing to suit the sprinklers, rather than to arrange the sprinklers to suit the timber-spacing.

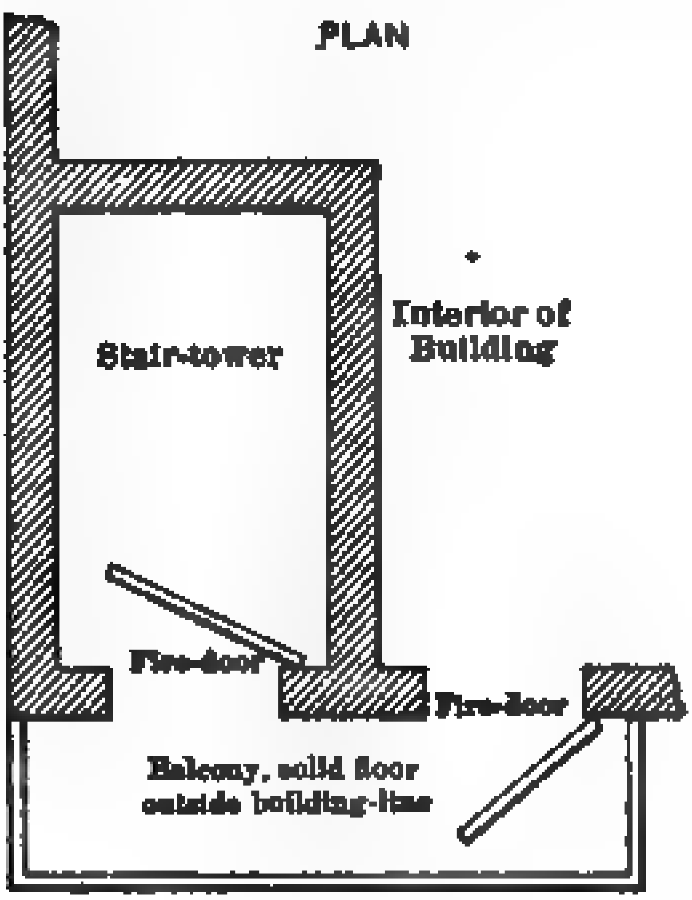
Mill-Construction Adapted to Warehouses. The features of bad construction mentioned under WHAT MILL-CONSTRUCTION IS NOT are as objectionable in warehouses as in factories, while the construction advocated for mills may be used with almost equal advantage in the erection of warehouses. But as the latter are usually erected in the more thickly settled portions of a city, they are more subject to the dangers of a conflagration; and it should be understood that even the best SLOW-BURNING CONSTRUCTION will stand but a short time after a fire has obtained a good headway, the main object of MILL-CONSTRUCTION being to retard the spreading of fire by the use of heavy timbers and the absence of concealed spaces. In applying the principles of MILL-CONSTRUCTION to warehouses, therefore, the general principle of using large timbers placed as far apart as the loads will permit, and of avoiding all concealed spaces, should be constantly kept in mind.

Warehouse-Floors, however, are generally required to sustain heavier loads than are found in woolen and cotton-mills, and hence require heavier construction. While WAREHOUSE-FLOORS are quite often built with transverse girders, 8 or 10 ft apart, the spaces being spanned by flooring from 4 to 6 in thick, a more common method of construction is to use one or more lines of longitudinal girders supporting floor-beams spaced as far apart as possible, preferably not less than 8 ft on centers.

Area and Height. The AREA of buildings of this type should be, preferably, not over 7 500 sq ft, and in no case should it exceed 15 000 sq ft between fire-walls. If buildings of LARGE AREA are required, it is advisable to divide them into

separate sections by fire-walls, thus reducing the liability to one fire, and affording an opportunity of storing hazardous goods in one or more sections, and non-hazardous or less hazardous goods in the remaining sections. Where ground is available, it is better to have a building of LARGE AREA AND LOW HEIGHT divided into fire-sections, than to have a building of LESSER AREA and GREATER HEIGHT, as the former construction affords a more economical handling of goods, and less concentration of values. Buildings of this type should be limited to 65 ft in height, and to six stories, thus discouraging the overloading of floors. Piled goods should be kept at least 18 in away from beams, thus allowing for the distribution of water from the sprinklers.

Walls should be of brick, and not less than 13 in thick in the upper stories, and they should be increased in thickness on the lower floors to take care of additional loads. PARTY WALLS should be increased at least 4 in in thickness, and all walls should be laid in cement mortar, should extend above the roof at least 36 in and be coped with stone, salt-glazed terra-cotta, or similar noncombustible materials. OPENINGS IN DIVISION WALLS should be limited to as few as possible, not over three in each story, they should not exceed 80 sq ft each in area, and should be protected by double, automatic, sliding fire-doors as specified elsewhere. (See Chapter XXIII, page 907.)



Note: Walls of brick or other approved material, built solidly from foundations to at least 36 inches above roof. Stair-treads, etc., of fire-proof material.

Fig. 19. Tower Fire-escape. Outside-balcony Entrance

Openings in Walls. As a protection against fires from surrounding properties, OPENINGS IN OUTER WALLS should be small, limited to as few as possible and protected by standard fire-shutters and doors, or standard wire-glass windows. If the surrounding buildings are of hazardous occupancy or inferior construction, and the distance between the warehouse and the latter but a few feet, shutters are preferable, as wire-glass windows are recommended only where the exposures are moderate. Even though the building is not exposed

fire from other buildings, the protection of WINDOW-OPENINGS may prevent
he spread of fire from story to story through the windows.

Girders and Beams which support the floors and roof should be SINGLE
ECES, not less than 6 in in least dimension, and with a sectional area of not
ss than 72 sq in; while columns should be not less than 8 by 8 in in cross-
ction in the upper story, and should be increased in size in the other stories
take care of any additional loads. The beams and girders should be SELF-
LEASING (Fig. 2), and the floors should be built as outlined under STANDARD
ILL-CONSTRUCTION, page 760, inclined at least 1 in in 20 ft, made as nearly
ater-proof as possible, and scuppered to the outside of the building. These
uppers should be set in brick-work at frequent intervals, of sufficient size to
ry off the maximum amount of water from each floor, and so constructed
at they will prevent the admission of cold air to the building. (See Fig. 11.)

Towers. The floors should be continuous from wall to wall, avoiding holes
r belts, stairways, elevators, etc. All such openings should be enclosed in a
ICK TOWER or in TOWERS extending not less than 36 in above the roof, coped
above, and accessible from each story by means of an outside balcony (Fig. 19).

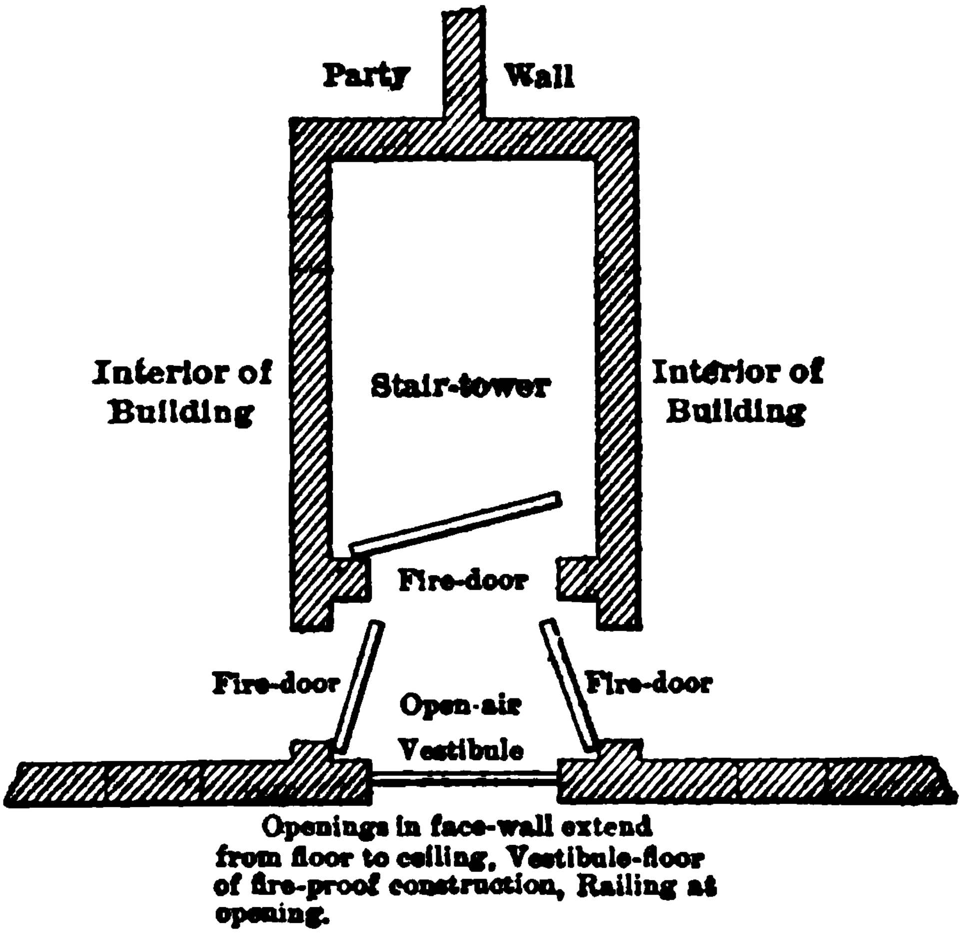


Fig. 20. Tower Fire-escape for Adjoining Buildings

here it is impossible, owing to the location or otherwise, to have these open-
gs on the outside, they should be placed in BRICK TOWERS constructed inside
e building and connecting with an entrance to a fire-proof vestibule, open to
e weather. There should be openings from each story to the vestibule, each
otected by standard fire-doors (Fig. 20).

Gravity-Tanks for Automatic Sprinklers are usually placed on extensions
such towers, and they should be built to carry the additional load imposed.
y access to the roof of the building may be had from a window or windows
ed in the tower, and such opening or openings should be protected by fire-
tters, especially where the tower is elevated a sufficient distance to allow
tank to be placed inside of the tower, thus preventing flames from gaining
ss to the tower and destroying the tank and tank-supports.

Boilers should be, preferably, in a separate building, cut off by stand fire-doors from the warehouse; or, if in the main building, should be located a room of FIRE-PROOF CONSTRUCTION, access to which should be from outs the building only.

Structural Steel Members should never be used in this type of constructi as they will not resist even a moderate fire. If used, they should be protec with fire-proof material. The lintels should be brick arches and not s sections.

10. Steel and Iron Structural Members in Warehouse-Constructi

Metal versus Wooden Standard Members. Owing to the fact tha beam or column of STEEL or WROUGHT IRON when heated will fail by buckl or bending very much sooner than an equivalent beam or post of WOOD, i important that such members be of WOOD, provided that the WOODEN BE have a sectional area of at least 72 sq in, and are not less than 6 in in least dim sion, and that WOODEN COLUMNS have a sectional area of not less than 8 by 8 CAST-IRON COLUMNS, also, will generally fail in fire and water sooner t wooden columns.

Fireproofing Steel Beams and Girders. When STEEL BEAMS and c UMNS are used, fireproofing is necessary to make them as FIRE-RESISTING the floors. Such be and girders may be FI PROOFED as shown in 21. Metal-wire m should be placed shown, and tied to beams and girders metal clips; and insure rigidity during pouring of the conc and to keep the mem alignment, forms sh be used. The conc should be poured be the floors are laid, after the wooden be are in position. A completion, the insulation should be at least 1 in at the edges of flanges, 2 in under the lower flange of the beam and 3 in under the lower fl of the girder. The webs should be filled solid. Where there is little sto of a combustible nature in the building, the beams may be protected as sh in Fig. 22. (See, also, pages 863 to 866.)

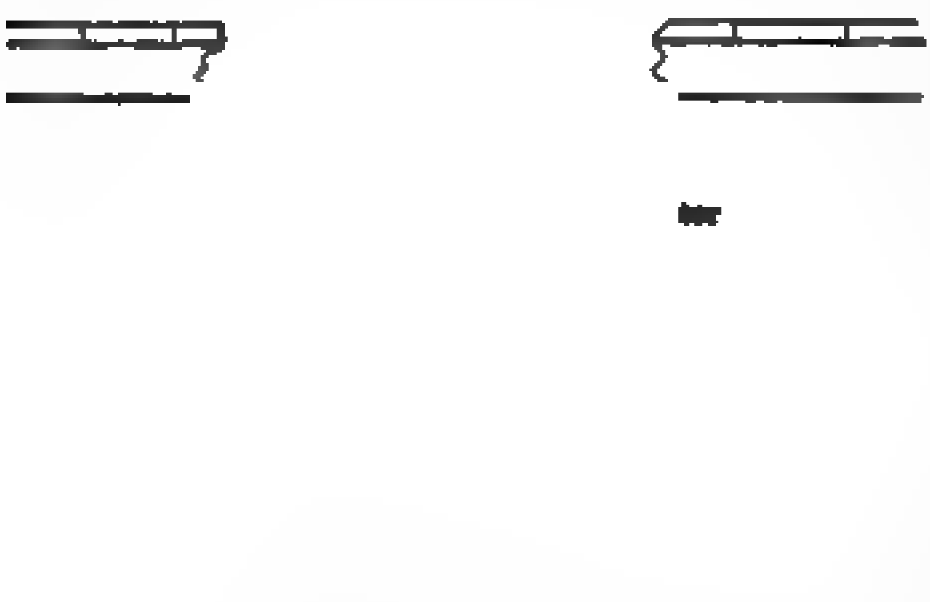

Fig. 21. Fireproofing of Steel Beam with Concrete and Plaster

Fireproofing Metal Columns. COLUMNS, either STEEL, WROUGHT-I or CAST-IRON, should be protected even to a greater extent than girders and bea and should have at least 3 in of concrete at the flanges, at least 1½ in at edges, and be filled solidly against the webs. Fig. 23 shows two columns prote by concrete held by wire mesh on ⅝-in rods, and all securely held to the col by metal clips. Forms should be used and the concrete should be poure the girders and beams are protected. Steel beams, girders and columns difficult to protect, especially at the intersections of steel and wood, and insulating material can best be applied before the floors are laid. The proofing of these members will be of little avail, unless the materials are g

tied to the metal members, and applied by workmen who understand such

Fig. 22. Fireproofing of Steel Beam with Metal-lath and Plaster

Fig. 23. Fireproofing of Steel Columns with Concrete and Plaster

24 illustrates the PROTECTION OF A ROUND COLUMN by reinforced concrete, the concrete is held in position re mesh on metal furring, held sition by metal clips or ties. reproofing should be at least 4 k, and forms should be used in nding the columns. In addition above reinforcements for these as, lateral reinforcement should ed by means of iron rods wound y around mesh, and placed 12 in nters. After the forms are re-, and the wooden floors are laid, lumns and girders should be d with a 1-in thickness of hard, filling all interstices between the woodwork and the insulation. Tile,

Fig. 24. Fireproofing of Cast-iron Column with Concrete and Plaster

owing to the difficulty of properly bonding it, is not as effective as concre but if securely bonded by means of metal, it is quite satisfactory. Fig. illustrates the PROTECTION OF A GIRDER AND A COLUMN by means of tile. The are other equally efficient methods of beam and column-protection, describ in Chapter XXIII. In buildings of warehouse-construction, heavy goods a

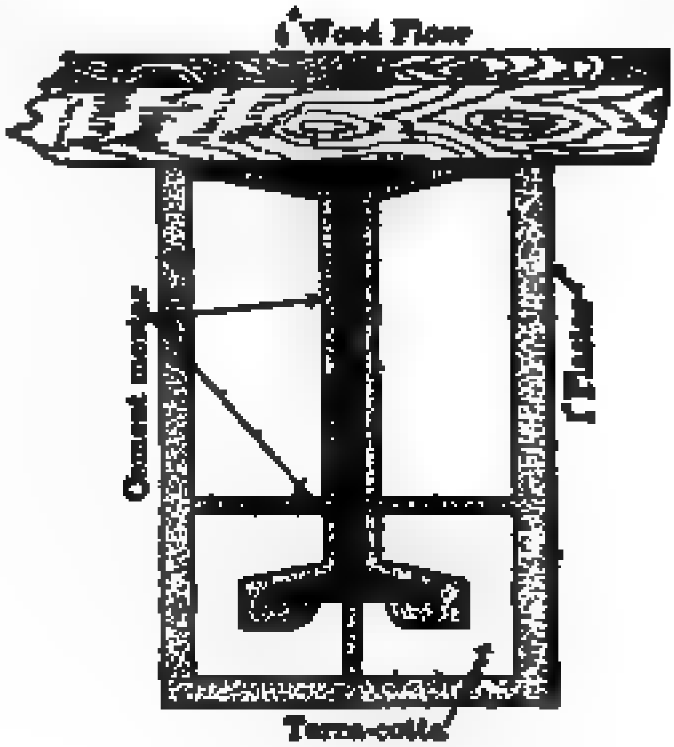

Fig. 25. Fireproofing of Steel Columns and Beam with Tile

handled, and it may be advisable to protect the base of each column with she metal to a height of 36 in above the floor, to prevent any weakening of the fi proofing. (See, also, pages 822 to 827, Figs. 1 to 13.)

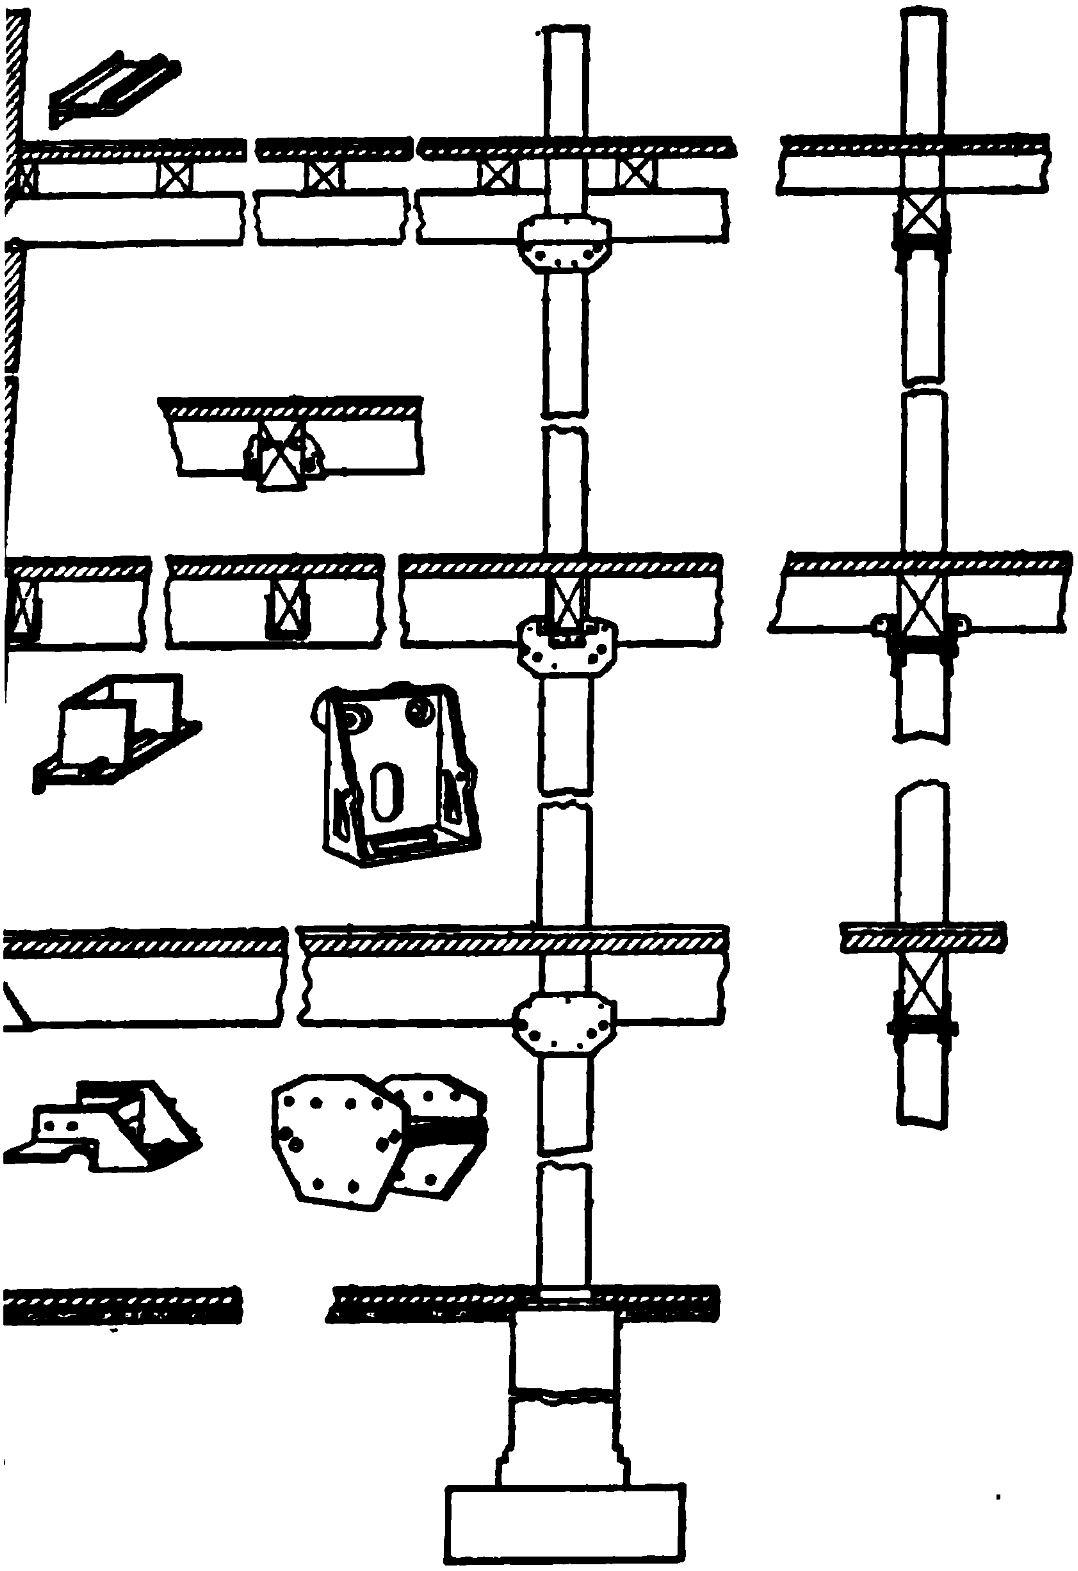
Pipes for Gas, Water, etc., should not be enclosed in column or gird insulation. (See, also, page 827.)

11. Structural Details of Mill-Construction as Applied to Factories and Warehouses

Column, Girder and Joist-Framing. Fig. 26 illustrates the method carrying the girders from the walls, posts, etc., the bottom post resting on a st POST-BASE. The first floor above the basement is shown with longitudi girders only, and heavy mill-flooring set on them. The girders are framed the post in a steel POST-CAP, and are hung clear of the wall in an approv steel WALL-HANGER. The next floor above shows the construction in which joists are framed into the girders by means of JOIST-HANGERS. The frami at the post, also, is done by means of a DUPLEX FOUR-WAY POST-CAP, while girder is built into the wall in a DUPLEX WALL-BOX. The JOIST-HANGERS used singly or opposite each other as required and are bolted to the gird thus tying the building laterally. The upper floor shows the joists resting the girder. This construction, however, does not conform to strict m CONSTRUCTION, as it exposes a larger amount of timber-surface. The gird is shown built into the wall and resting on a WALL-PLATE. This distributes load over the masonry but is not as effective in preventing dry-rot as the wa BOX or WALL-HANGER.

Steel and Malleable-iron Post-Caps and Bases. Fig. 27 illustrates o details of construction which may be used. The bottom post rests on a s POST-BASE. The POST-CAP shown on the bottom post is a DUPLEX FOUR-

st-cap, while the post-cap above it is one of the malleable-iron type, by the National Board of Fire Underwriters. The post-cap shown p, also, is of malleable iron and intended for lighter construction or s which run across the post as shown. The girders in every case are ear of the wall by means of approved wall-hangers and the beams d by the girders in malleable-iron joist-hangers.



. Mill-construction. Column, Girder and Joist-framing

t-Caps and Bases. Fig. 28 illustrates other details of con- owest post rests on a heavy, cast-iron, ribbed post-base. r-girders are carried at the post by means of heavy, cast-iron built into the wall in cast-iron wall-boxes. When cast st-caps it is essential that it be made extra-heavy, as cast ain on account of the uneven shrinkage when cooling, which al stresses and weakens the caps. Flaws, also, may develop

during the manufacture which weaken the caps and greatly impair the saf of the building. An objection to cast iron is its tendency to crack and be during a fire when cold water is thrown on it. The POST-CAPS shown in Fig. are of cast iron for the first and second floors, Duplex steel for the third fl and malleable iron on the top post.

Fig. 27. Mill-construction. Malleable-iron Post-caps and Bases

Duplex, Combination Post-Cap. Fig. 29 illustrates the use of the Dup COMBINATION POST-CAP on the bottom post. This cap is made with a mallea iron lower part and a steel upper part. The POST-CAP shown on the sec post is called the IDEAL POST-CAP and consists of a steel upper part with angles riveted underneath to fit the post. The cap shown on the top

Fig. 29. Mill-construction. Cast-iron Post-caps and Bases

Steel Post–Caps. Fig. 30 illustrates various forms of steel POST-CAPS. The IDEAL POST-CAP is shown on the bottom post and the VAN DORN POST-CAP on the post next above. On the top post the STAR POST-CAP is shown. This has a fin for which the top of the post must be slotted to receive it. Steel JOIST-

HANGERS are shown for the two lower floors. The IDEAL JOIST-HANGER illustrated in the lower floor. It is spiked to the sides and top of the gird The VAN DORN JOIST-HANGER is shown in the second floor, while the old-sty STIRRUP is shown in the top floor. The WALL-HANGERS illustrated are of t approved type.

Fig. 30 Mill-construction. Combination Post-caps, etc.

Framing Steel Beams and Girders. Fig. 31 illustrates the use of I-BE GIRDERS in place of WOODEN GIRDERS and their connections with wooden bea In this kind of construction it is necessary to fireproof the steel beams, as t are more readily affected by heat in case of fire than large wooden timb Intense heat often causes them to collapse and ruin a building. The HAN

...em in the first floor is used where the I beams and wooden beams are of the ...e height. This HANGER provides an extra bearing for the timber and has ...oved very satisfactory. The HANGER shown in the second floor is used when ...is necessary to raise the wooden beam above the lower flange of the steel ...m. This HANGER brings all the load on the lower flange of the I beam and

Fig. 30. Mill-construction. Steel Post-caps, etc.

...vides an anchorage for the wooden beam. It is used singly or in pairs on ...t beam as required, and is bolted through the web of the I beam. This has ... found to be a very economical and efficient construction. In the third ... the wooden beam is shown framed to the I beam by means of a SHELF-...ER. With this form of construction it is necessary to rivet the SHELF-

Fig. 31. Mill-construction. Framing Steel Beams and Girders

ANGLE to the web of the I beam. The upper detail shows the old-fashion STIRRUP passing over the top flange of the I beam and carrying the wood beam. The POST-CAPS shown are the DUPLEX STEEL POST-CAPS which approved by the National Board of Fire Underwriters.

12. Connections of Floor-Beams and Girders

Girder-Hangers and Joist-Hangers. To render the construction, and ticularly the girders, SLOW-BURNING, it is important to have no hollow spaces tween the top of the girders and the flooring, that is, to have the top surface of the floor-beams flush with that of the girders. This, of course, necessitates framing the floor-beams into the girders. For HEAVY CONSTRUCTION the only kind of framing that is permissible is one in

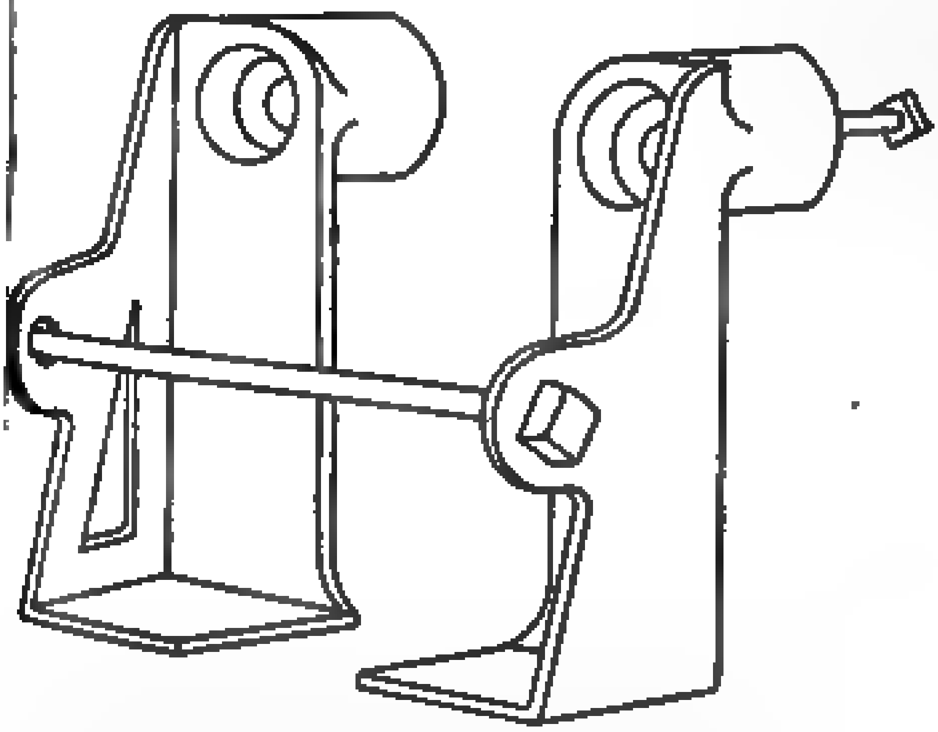


Fig. 32. Duplex Hanger for Heavy Floor-beams

Fig. 33. Framing I Beam and Wooden Beam of Same Depth

hich some kind of JOIST-HANGER is used. The rious kinds of JOIST-HANGERS now in the market ve been illustrated and commented on in the last part of Chapter XXI. hen the floor-beams are 6 by 12 in or larger in cross-section, and the girders e of wood, the author would give the preference to the DUPLEX HANGER own in Fig. 32. (See, also, pages 752 and 753.)

If STEEL-BEAM GIRDERS are used in place of WOODEN GIRDERS, there are veral methods in use for ming the wooden beams. g. 33 shows a steel I beam, d a wooden beam of the me depth framed into it d resting on its lower flange. most cases, however, this s not afford a sufficient ting for the wooden beam. g. 34 shows a SHELF-ANGLE ted to the web of the I m. Whenever this method supporting the beams is d, enough bolts or rivets uld be used to support the d carried by the SHELF-LES. Each ¾-in bolt may considered to support 3 000 n each side of the girder, each ⅞-in bolt, 4 000 lb.

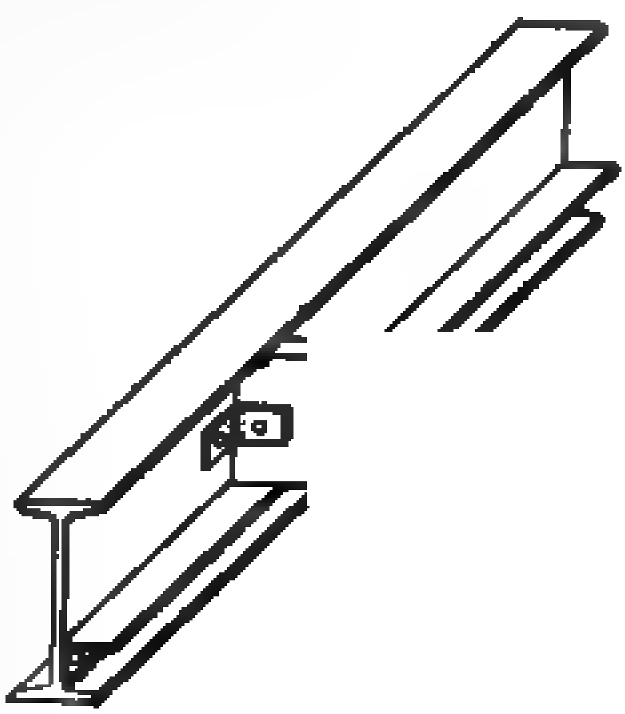

Fig. 34. Wooden Beam Framed to I Beam with Shelf-angle

methods shown in Figs. 35 and 36 are sometimes used, but are open to ction on account of the weakening of the wooden beams when loaded. 37 shows a STIRRUP-TYPE of hanger. This construction permits the

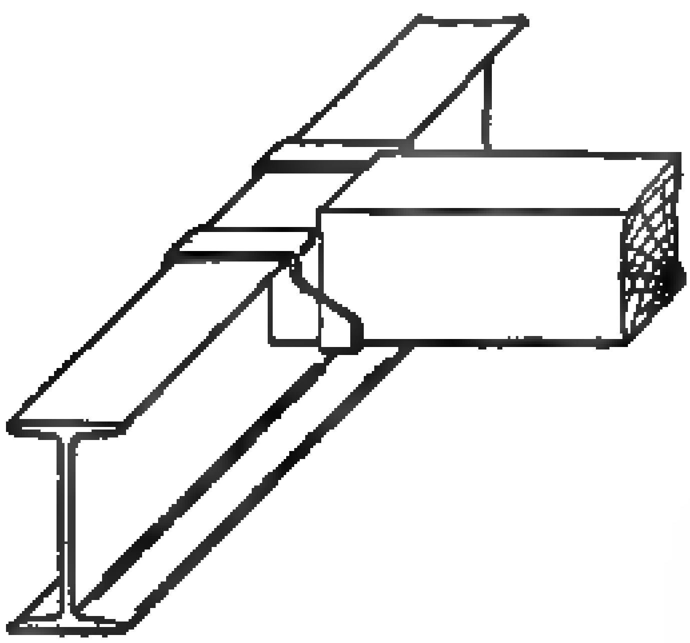

Fig. 37. Wooden Beam Framed to I Beam with Stirrup-hanger

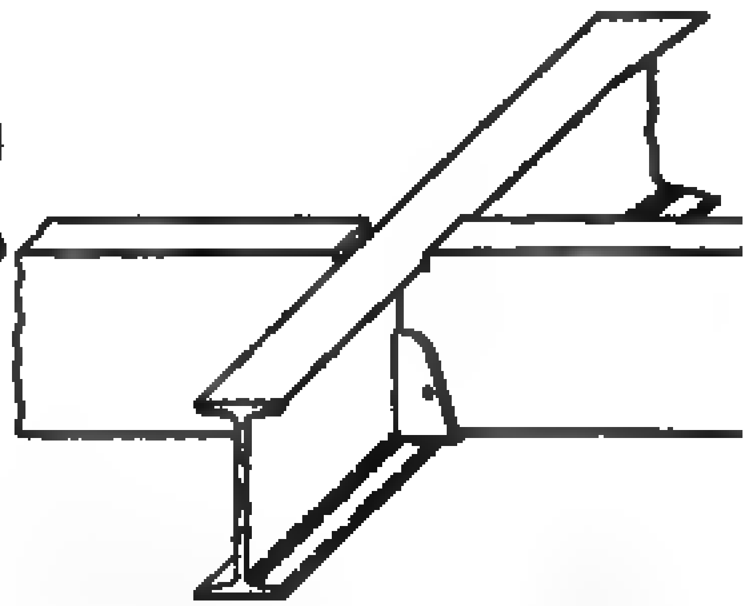

Fig. 38. Wooden Beam Framed to I B with Duplex Hanger

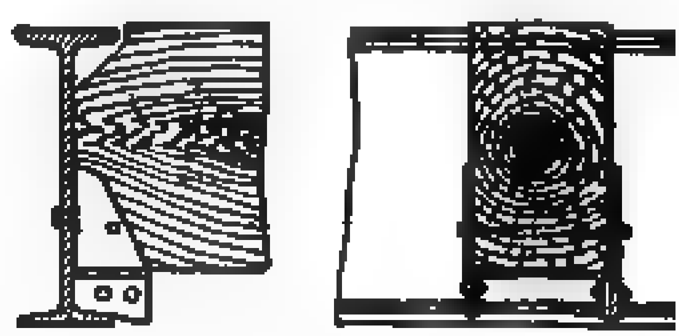

Fig. 39. Wooden Beam Framed to I B with Duplex Shelf-hanger

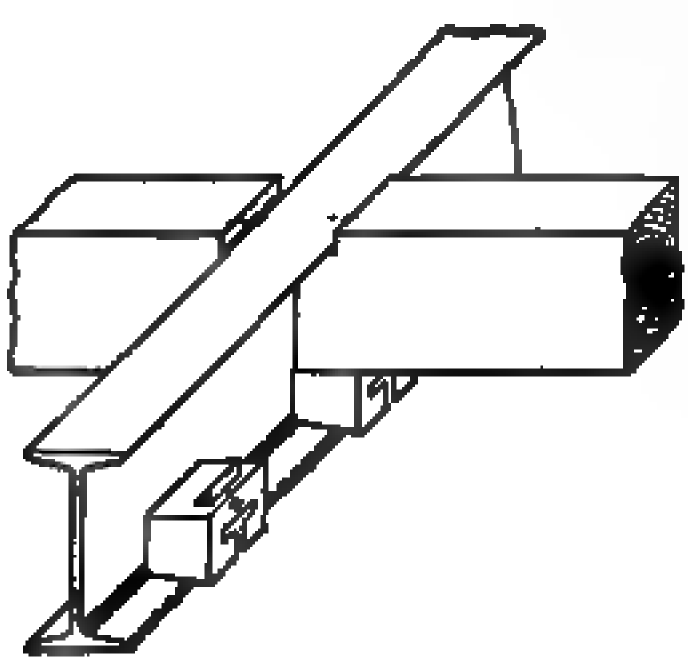

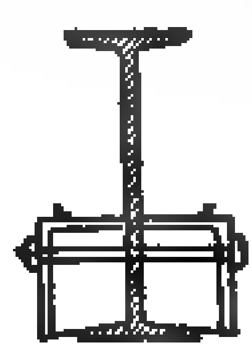

Fig. 40. Wooden Beam Framed to I Beam with Duplex Box-hanger

ing of the wooden beam at any desired height, and has proved satisfactory. hese hangers can be used with any depth of beam or girder, and are furnished y all manufacturers of steel JOIST-HANGERS of the various types, as well as by lacksmiths who can make WROUGHT-IRON STIRRUPS. Fig. 38 shows the DUPLEX-TYPE OF HANGER for framing a wooden beam flush with the lower flange f the I beam. This hanger is attached by means of bolts. Fig. 39 shows

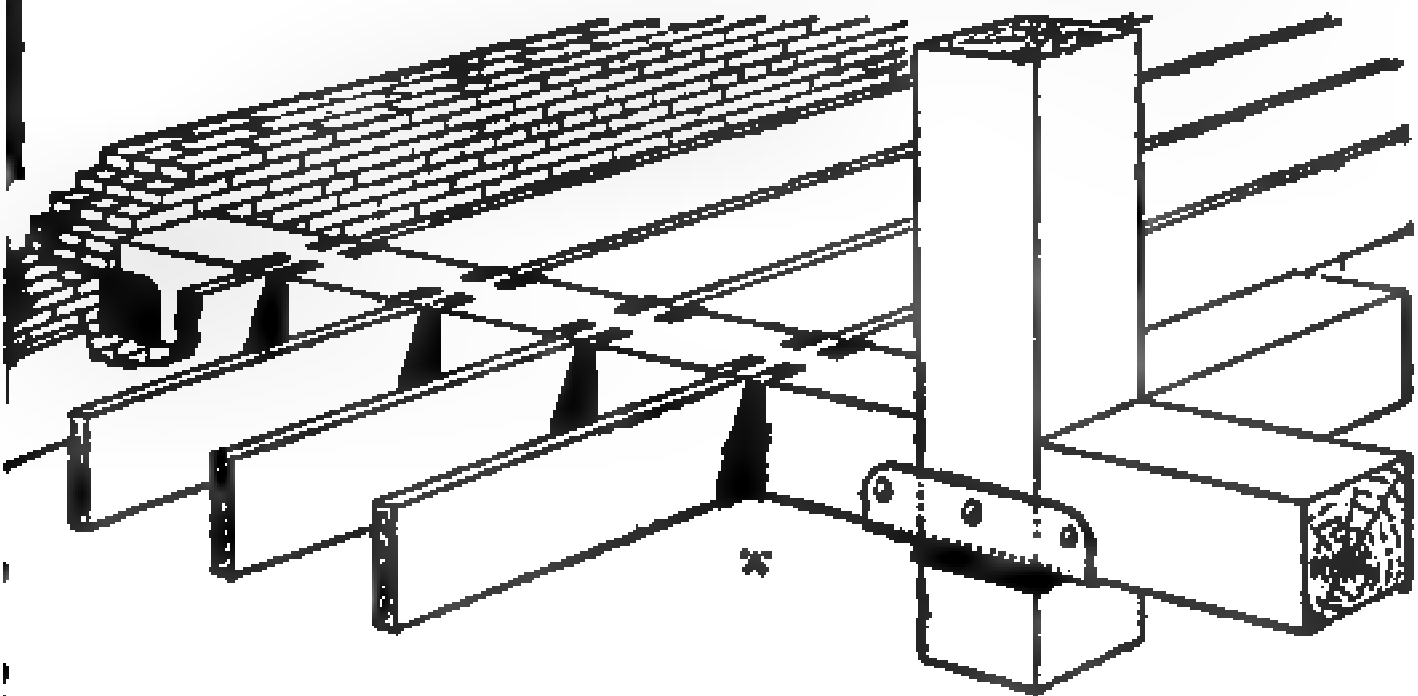

Fig. 41. Floor-framing with Van Dorn Hangers and Post-caps

e same design of HANGER, with the SHELF-CONSTRUCTION used to carry e wooden beams up to 4 in above the lower flange of the I beam. Fig. shows a HANGER for carrying the wooden beams 4 in or more above the wer flange of the I beam.

The HANGERS described in Figs. 38, 39 and 40 are all of the DUPLEX TYPE, d are so constructed that all the load is carried on the lower flange of the

Fig. 42. Floor-framing with Duplex Hangers and Post-caps

m, which is a very satisfactory and ideal construction whenever it is ssary to frame wooden beams into and not rest them on the I beams. The n is a very economical one for framing wooden beams to I beams, as the s for attaching these HANGERS can be punched while the steel is being fabri-

cated, and the HANGERS are attached to the steel beams by means of bolts w the wooden beams are put in place. These HANGERS are provided with or lag-screws for anchoring the wooden beams securely to the steel gir Fig. 41 shows a floor-framing with the VAN DORN STEEL HANGERS. Fig. shows the floor framed with the DUPLEX TYPE OF HANGER and POST-CAP. same principle of construction is applicable to larger wooden beams sp farther apart.

12. Wall-Supports and Anchors for Joists and Girders

Box Anchors, Wall-Hangers, etc. Anchoring. In a warehouse inten to be constructed on the SLOW-BURNING PRINCIPLE, the floor-beams and gir should be anchored and supported by walls in such a way in case the beams burned through, the may fall without inju the walls, and w large timbers are u provision should be m against the possibilit dry rot.

Fig. 43. Early Form of Beam-support in Mill-construction

Box Anchors. method of supporting beams in MILL-CONST TION as originally veloped in the New land mills is show Fig. 43. This full the requirements al mentioned, but it weakened the walls to some extent. The GOETZ CAST-I

Fig. 44. Goetz Box Anchor for Wooden Beams

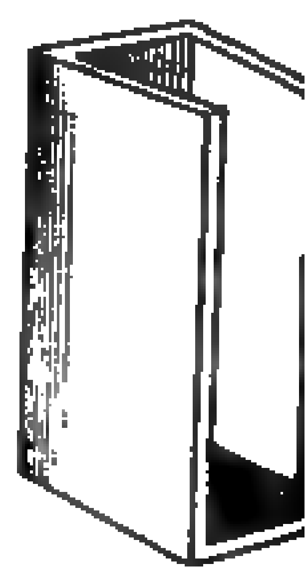

Fig. 45. Goetz Box chor for Wooden B

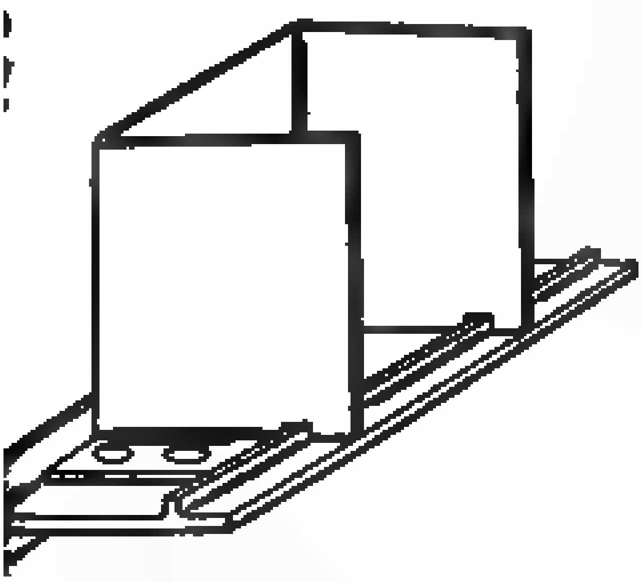
BOX ANCHORS shown in Figs. 44, 45 and 46 and the DUPLEX WALL-BOX sh in Fig. 47 are decided improvements on the anchor shown in Fig. 43, as

nd all the advantages of the latter without weakening the walls, unless the r-beams are very wide. The WALL-BOX as shown in Fig. 47 is made h a malleable-iron bottom plate and a steel box above. It has a rib the plate at the back, which extends up and down, and acts as a secure horage in the brickwork. These WALL-BOXES are made wedge-shape, d it is therefore possible to pull m out of the wall. e more weight re is on the beam, stronger will be bond that holds beam to the box d the box to the ll.

n case of fire or ident, the joists burn through or ak and in falling y can free themves from the anorage and leave wall standing.

Fig. 46. Goetz Box Anchor for Wooden Girders

e wall is not even weakened by the space left in it, because the box ains, and the crushing strength of this CAST-IRON BOX is much greater than t of the wall. No break or breach is made in the wall, and the box that ains, securely held, forms a space for the easy replacement of the wooden m. The box provides a perfect and secure foundation for each beam. from a defective flue cannot ignite a beam-end, because it is protected by a ventilated, CAST-IRON BOX. The WALL-BOXES have air-spaces, also, in the sides, ½ in wide, which permit a circulation of air around the ends of the beams, effectually preventing dry rot. If timber is wet or unseasoned these wall-boxes allow it to dry out after it is put in the building. The average weight of a box like that shown in Fig 45, for 2 by 12-in joists, is 10 lb.



. 47. Duplex Wall-box with Ribbed Plate

Wall-Hangers. Another device for obtaining the same results in a different way is the WALL-HANGER. Figs. 48 and 49 show DUPLEX WALL-GERS for large timbers. The hanger shown in Fig 49 is made of open-hearth l and is extra-heavy. Each of these hangers is provided with a plate which has -in bearing on the wall, and the bearing of the timbers on the hanger is also . For beams not exceeding 10 in in breadth there is probably little choice een the BOX ANCHOR, Fig. 46, and the WALL-HANGERS, Figs. 48 and 49, pt perhaps in the price and appearance. When the WALL-HANGER is used, le is left in the wall, and a saving of 6 in in the length of the beams is ed, which in some cases would be a consideration. For girders 12 by 14 in upwards in cross-section, the author believes that the hanger shown in

Fig. 49 is preferable to the BOX ANCHOR. WALL-HANGERS made from STIRRU should not be used for heavy beams. The use of any one of the hangers

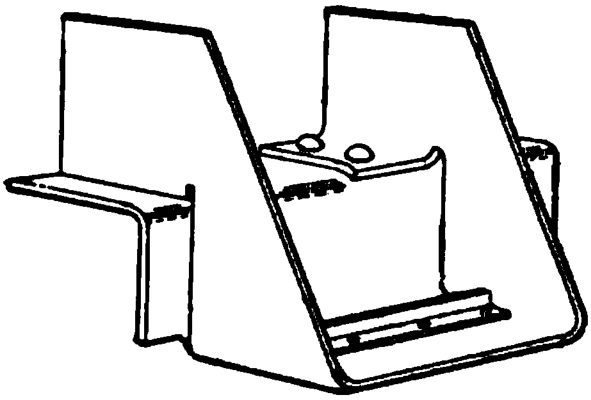


Fig. 48. Duplex Wall-hanger for Large Wooden Girder

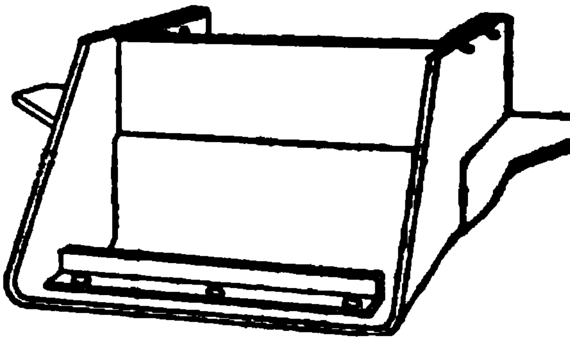

Fig. 49. Duplex Extra-heavy W hanger for Large Wooden Girde

boxes is obviously greatly superior to the ordinary method of anchoring bea or girders to walls, and the use of such hangers will undoubtedly save much which would be caused by the falling of the walls. These are almost invarial

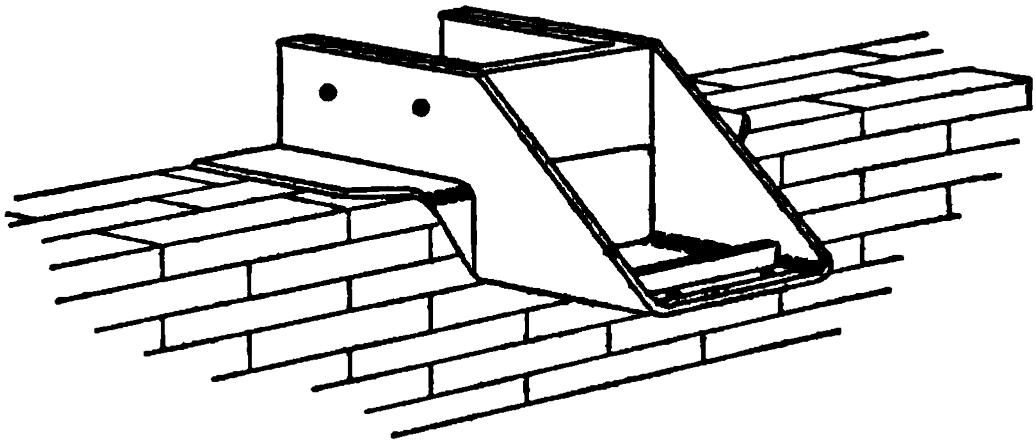

Fig. 50. Application of Wall-hanger to Brick Wall

pulled down by the ORDINARY IRON ANCHORS when the beams fall. Fig. shows the application of a WALL-HANGER.

14. Weakness of Wrought-Iron Stirrups when Exposed to Fire

Stirrups and Fire-Tests. Referring to this subject, Professor J. B. Johns of Washington University, said: "The recent fire-tests of STEEL STIRRUPS brick walls which were made under my supervision in this city (St. Lou show very conclusively that unprotected stirrups are extremely danger These stirrups become red-hot in a few minutes and then rapidly char burn away the ends of the beams; and they also bend down, so that in f twenty to thirty minutes after the fire reaches the stirrups, the beam is drop right out of the twisted steel by the straightening out of this bend or twist."

The Duplex Hangers possess an advantage over STEEL STIRRUPS becau being of malleable iron, they are not as quickly affected by heat, there no twists or bends to straighten, and the bearing in the trimmer or header i a great degree protected by the form of construction. During the severe at Paterson, N. J., February 9, 1902, some DUPLEX WALL-HANGERS were s jected to a most severe test without apparent injury. It is undoubtedly d able that all structural iron should be protected from fire, but it is almost practicable to effectively protect the STIRRUPS used in connection with woo beams without going to a greater expense than the character of the construc warrants.

15. Post and Girder-Connections

[Iron] Cap-Plates, Wooden Bolsters, etc. Whenever a building is con-[str]ucted with wooden posts extending through several stories, each upper post [sh]ould rest on an IRON CAP-PLATE, fitted over the post below, and never on a [gir]der or even on a WOODEN BOLSTER. A BOLSTER would not be objectionable [we]re it not for the fact that the pressure under the post is generally sufficient to [cru]sh the fibers of any kind of wood. Then, too, there is always some settle-[men]t due from shrinkage. As posts are used expressly for the support of beams [and] girders, the IRON CAPS must, of course, extend sufficiently beyond the upper [po]st to afford ample bearing for the end of the girder. This bearing in square [inc]hes should be equal to at least one-half the load on the girder divided by the [saf]e resistance of the wood to crushing across the grain, as given in Table IV, [pag]e 454.

[Ex]ample. A 12 by 14-in yellow pine girder is designated to support a possible [loa]d of 38 000 lb. What bearing should it have at the ends?

[So]lution. The safe resistance given for long-leaf yellow pine to crushing across [th]e grain is 350 lb per sq. in. One-half the load on the girder is 19 000 lb, [an]d hence the bearing area should be 19 000 divided by 350 or about 54 sq in. [A]s the breadth of the beam is 12 in this would require a bearing lengthwise [of] the girder of 4½ in. In no case should the bearing be less than that required [by] the above rule.

16. Form and Material of Post-Caps

Cast-Iron versus Steel Post-Caps. Formerly CAST-IRON POST-CAPS were [use]d for the framing of the girders at the columns and posts. But the uncer-[tain]ty attached to the use of cast iron, and the necessity of extremely heavy [part]s to assure safe construction have led most engineers to specify STEEL POST-[CAP]S, as they are unquestionably the strongest form of construction for fram-[in]g posts and girders. The use of STEEL POST-CAPS is to be recommended, there [bein]g no uncertainty regarding the strength of steel as there is concerning the [stre]ngth of cast iron used for post-cap construction. Internal stresses due to [une]ven cooling may seriously affect the strength of a CAST-IRON CAP, while a [hon]eycombed casting may be used, undetected, and affect the safe carrying [cap]acity; so that failure of the cap may occur even from the vibration due to [the] machinery in the building.

[C]ast-Iron Post-Caps are still used in some localities and a few of the com-[mo]n forms as well as those of STEEL POST-CAPS are shown. Fig. 51 shows a [cap] which is frequently used for light construction. Fig. 52 shows a similar [cap] for a cylindrical post. These caps permit the use of girders wider than the [post]. When the girders and floor-beams are in place, and especially when the [buil]ding is occupied, there is no danger of the girders or posts slipping on [the] plate; in fact it would require a greater force to move them. The girders [shou]ld be tied together longitudinally by IRON STRAPS spiked to their sides. [Man]y persons, however, consider it important in a building of SLOW-BURNING [CON]STRUCTION, to have the posts tied together in vertical lines, and the girders [tie]d in such a way that they will be self-releasing without pulling down [the p]osts. Figs. 53 and 54 show two POST-CAPS which fulfill these requirements. [In] these caps the ends of the girders are not fastened by bolts or spikes, but [are] held in place and tied longitudinally by means of the LUG L on the GOETZ [cap] and by PINS on the DUVINAGE CAP; so that in case the girder is burned to [the b]reaking point, it can fall without pulling on the post. Provision is also [mad]e for bolting the cap to the upper post. The author doubts very much,

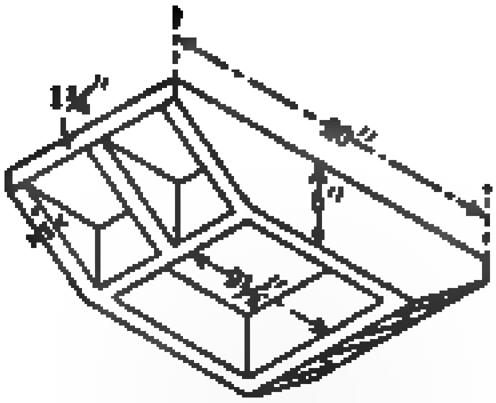

Fig. 51. Cast-iron Post-cap for Square-section Wooden Post

High Sides

er, if posts bolted together in this way will stand after the girders have as the planking will be likely to pull the posts over, even if they do not as quickly as the beams. Fig. 55 shows another form of CAST CAP with ides, allowing lag-screws to be driven in the holes to tie the girders.

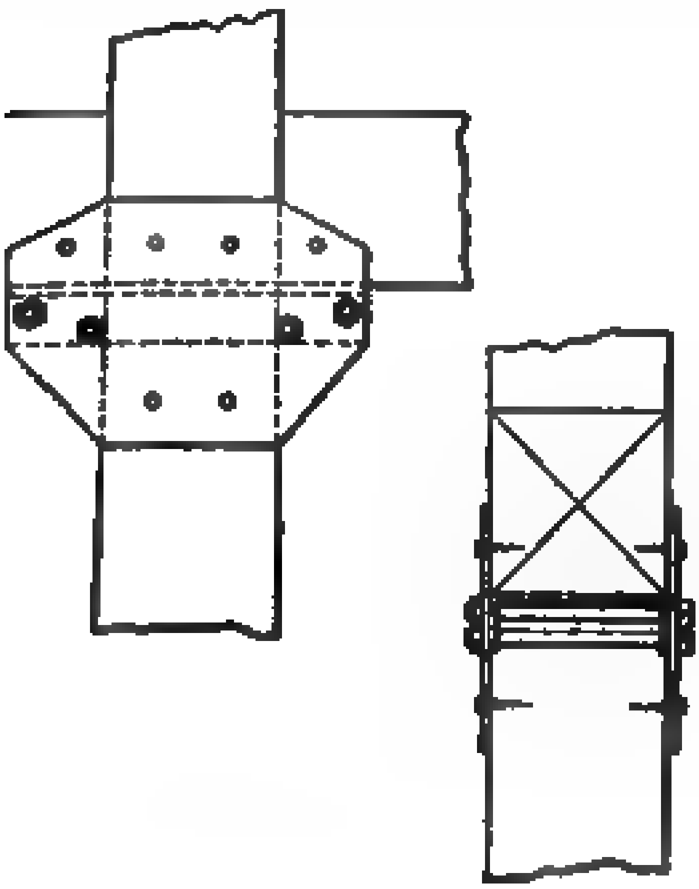

Fig. 56. Steel Post-cap with Side-plates and Brackets

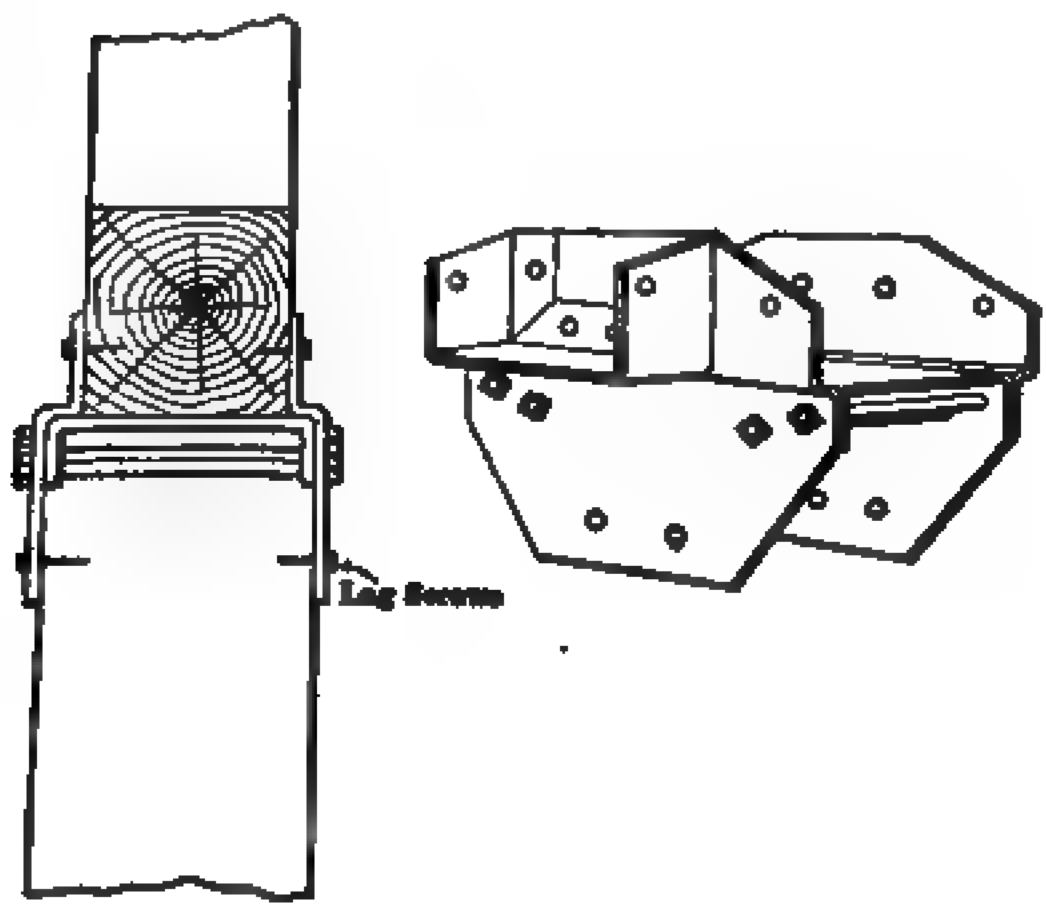

Steel Post-caps for Posts Varying in Section. Second Figure Shows Four-way Beam-construction

Post-Cap, which is approved by the National Board of Fire Under- d bears their label, is shown in Fig. 56. This POST-CAP is made up of plates and heavy steel brackets, all held rigidly together by means avy bolts. The posts and girders are fastened to the cap by means of

Fig. 58. Steel Post-cap. One-way Beam-construction

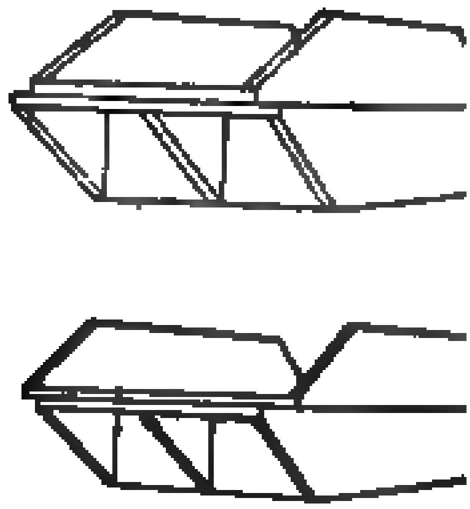

Fig. 59. Malleable-iron Po caps

Fig. 60. Steel Post-cap for Continuous Post

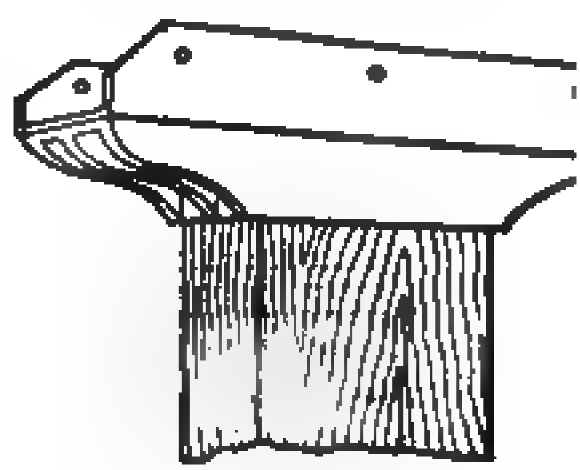

Fig. 61. Malleable-iron Post-cap Steel Top-plate

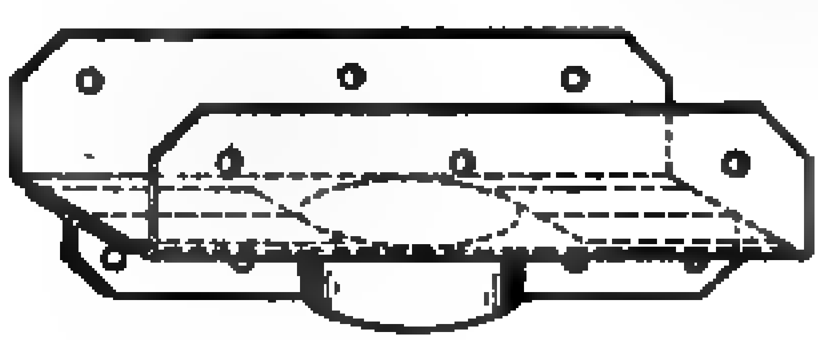

Fig. 62. Steel Post-cap for Cylindrical Wooden Post. Perspective

screws, permitting the girders to release themselves in case of fire. By method the entire construction is tied together vertically and longitudinally. is cap, on account of its simple design, lends itself readily to every form of struction desired.

Various Types of Post-Caps. Fig. 57 illustrates one POST-CAP in which e width of the girder is less than that of the post below, and also another POST-

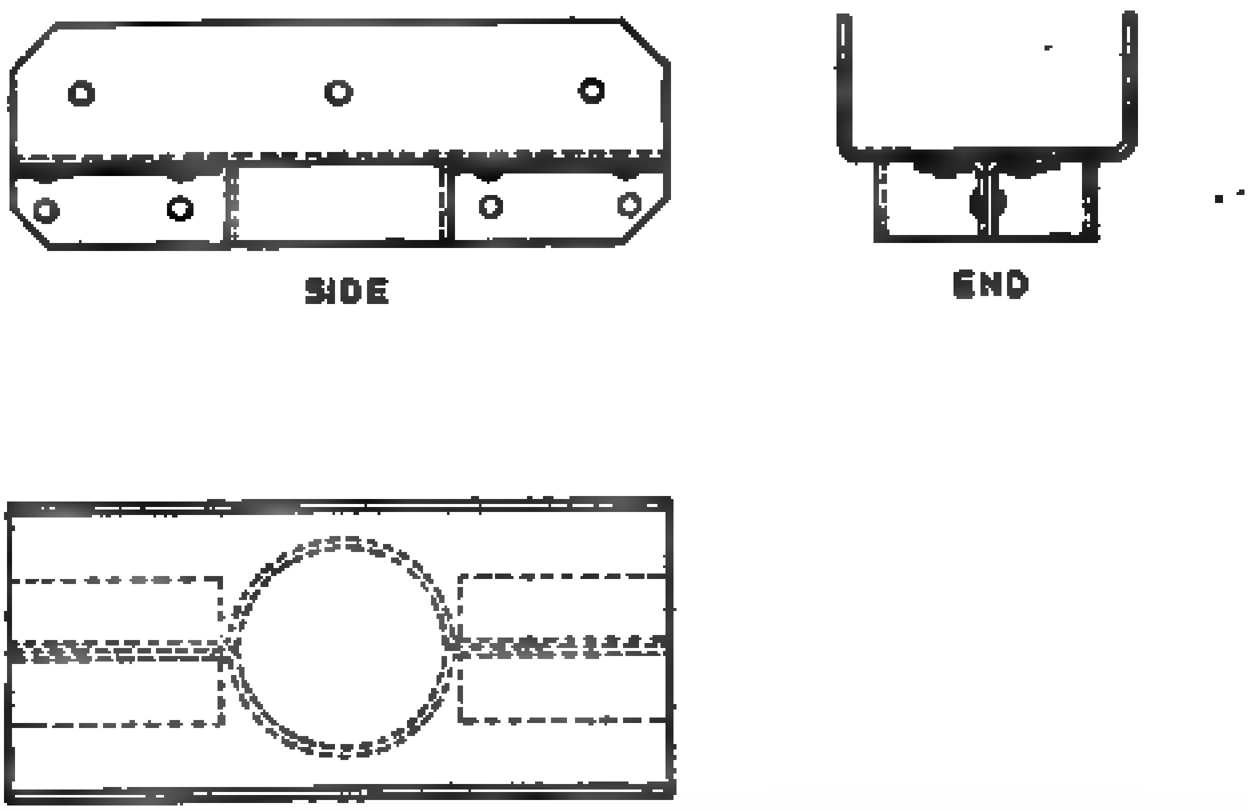

Fig. 63. Steel Post-cap for Cylindrical Wooden Post. Elevations and Plan

p in which the width of the girder is greater than that of the post below. In latter FOUR-WAY BRACKETS are riveted to the side-plates to provide for the R-WAY CONSTRUCTION. Fig. 58 shows a ONE-WAY CONSTRUCTION. Fig 60 ws a POST-CAP which is used when it is required to run a post through two ries. This is what is known as a CON-UOUS POST-CAP. The bracket instead being made clear across the cap is made ut on both sides and fitted into ulders notched into the post, so as make a more rigid construction. Fig. shows two POST-CAPS made of malleable n which are preferable to cast-iron caps they will not break off in case of a fire en cold water comes in contact with m. This danger is present when CAST-N POST-CAPS are used. The cap shown made in two parts so that it will fit ts and girders of different sizes. This , also, is approved by the Board of e Underwriters. Fig. 61 shows a COM-ATION POST-CAP, the upper part of which is made of steel plate, and the r part of malleable iron. Figs. 62 and 63 show STEEL POST-CAPS FOR D POSTS. They are also frequently used for pipe-columns and concrete-l columns. (See, also, Steel-Pipe Columns, page 469 and Lally Columns, s 474 and 477.) Fig. 64 shows a STEEL POST-CAP intended for lighter

Fig. 64. Steel Post-cap for Light Construction

construction. Fig. 65 shows VAN DORN POST-CAPS. Fig. 66 illustra STAR POST-CAP which is made of a bent steel plate with a fin projecting into a slot in the post. Both are approved by the Underwriters. It is ne

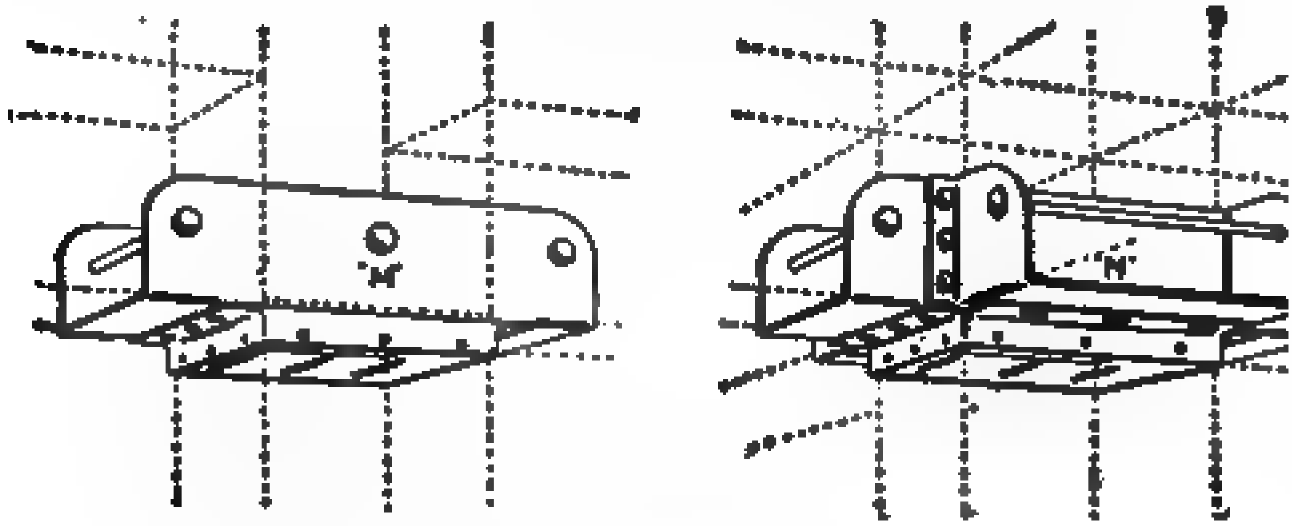

Fig. 65. Van Dorn Steel Post-caps

to slot out the post in order to insert this fin. POST-CAPS which co encircle the top of the post in a socket, to a great measure tend vent the twisting effect of the post, which is so noticeable when th are of wood. There is an o to the use of the FOUR-WAY P when the girders are of wood, the floor-beams that are hung girder drop a distance equal shrinkage in the girder, if th are hung in stirrups, or by this amount if they are DUPLEX HANGERS. The bea ported on the POST-CAP can at all, and consequently the be higher over the beam by the posts, than over mediate beams. In one where deep beams were unevenness in the floor a nearly an inch and was v able. Wherever wooden

Fig. 66. Star Steel Post-cap with Fin

used it is, therefore, a much better construction to support all of beams from the girders, in which case the shrinkage will be unifo steel girders there is no shrinkage, and a beam may be placed o posts with advantage.

17. Roofing-Materials

Warehouse-Roofs are almost always flat and, like floors, should ous from wall to wall, without openings. The occupancy of su calls for little light, and hence skylights and other roof-structures quired.

Dampness and Leaks. Stored goods may be very easily damag and roofs, therefore, should be of such construction that they will p ness, either through leakage or condensation. While roofs are usu flat as possible, the incline should be sufficient to drain readily, a

s should be of sufficient capacity to quickly drain the roof of a maximum ount of water.

ag or Tin are almost exclusively used on buildings of this type, although halt or other mastics are sometimes used with good results.

ag Roofs should be constructed generally as described on pages 1595 1599 and should be not less than 5-ply, with the maximum amount of coating. e flashings and counterflashings should be of copper or heavily-coated best e-plates.

in Roofs should be laid with the best open-hearth, palm-oil-process terne-es, laid on felt or other suitable material which will avoid condensation and as a fire-retardant.

nvas Roofing will stand hard usage, as is shown by its continued use on s of vessels and steamers; but it is not adapted to large buildings.

ovisions for Flooding Roofs. When warehouses are located in congested icts, surrounded by higher buildings, or by buildings of light construction zardous occupancy, their roofs should be so constructed that they may be d during severe fires in such surrounding buildings. This can be accom-d by using good roofing-materials, making high flashings, waterproofing alls above the roof-line, and providing roof-outlets of types that will allow acing of stoppers at the scuppers. (See Fig. 11.)

18. Partitions

n-bearing Partitions. This refers only to those light walls or enclosures separate rooms, etc., and not to those walls which divide the building into s. PARTITIONS, as here defined, bear no floor-loads. Buildings of the URNING TYPE, for occupancies described above, need but few partitions, se should be built of non-inflammable materials, preferably metal lath ster on light, metal studding. All cupboards, closets, lockers, etc., in ing of this type should be of metal, or other equally non-inflammable al.

19. Doors and Shutters

Underwriters' Specifications. Doors and shutters should be built as in the Rules and Requirements of the National Board of Fire Under-for the construction and installation of fire-doors and fire-shutters, as ecifications are accepted by architects and builders as the standard.

Openings should be limited to 80 sq ft, or less, each, and all communica-tween buildings or sections of a building protected with double, auto-ding doors.

20. Fire-Protection

atic Sprinklers, supplied with an ample quantity of water at a good are needed in mills, storehouses, factories, warehouses, etc., where ble goods are made or stored, or where large values are at stake. They ct, be installed in buildings of any type of construction and occupancy, ost effective in buildings of FIRE-PROOF or MILL-CONSTRUCTION.

Standpipes, with outlets in each story, in the basement and on the d be installed at points readily accessible in case of fire, and should icient quantity of good hose attached at each outlet.

ozzles. If a building is badly exposed to other buildings of inferior n or hazardous occupancy, a Monitor-nozzle of large size, located f, is advisable.

Public Water-Supplies. If these are not available, a private fire-se[...] may be advisable.

Competent Supervision. All of the above FIRE-PROTECTION EQUIPM[...] should be installed by men familiar with their operation, and supervised [...] competent FIRE-PROTECTION ENGINEERS, under plans approved by underwr[...] having jurisdiction.

21. Cost* of Mills and Factories Built on the Slow-Burning Princi[...]

Difficulty of Estimating Costs from Tables. The cost of a buildin[...] this type of construction depends upon the cost of material plus the co[...] labor, and as the cost of either varies greatly in different localities the co[...] similarly constructed buildings must also vary. Even if the cost of labor [...] materials does not vary, the cost of buildings of the same area will depend [...] upon the height, floor-loads, distance between bearing-points, design, etc.; [...] it is difficult to deduce a table accurate enough for use in computing even [...] approximate cost of buildings per square foot of floor-areas. One firm [...] architects † states: "Experience has taught us that estimating the cos[...] a building either by the SQUARE-FOOT METHOD or the CUBIC-FOOT MET[...] has proved dangerous and misleading, and it was abandoned by us m[...] years ago except to obtain a general idea of the cost of a building. [...] have found that the only reliable way to approximate the cost of a buil[...] is to block it out and to figure the approximate quantities, which at the ma[...] prices prevailing at the time the building is to be erected, will give the appr[...] mate cost of said building." Owing to the high cost of lumber, a FIRE-PR[...] building will cost but little, if any, more than a building of MILL-CONSTRUCT[...] and owing to this fact it is always advisable to determine the cost of build[...] of both types before deciding upon the type to be used. Buildings of M[...] CONSTRUCTION are becoming obsolete in some localities, and owing to the l[...] rate of insurance on buildings of FIRE-PROOF CONSTRUCTION, those of the l[...] type are much preferred, as in the end they cost less. It is not always sa[...] compare the TOTAL COST OF LABOR with the cost of the LABOR PER DIEM[...] the cheaper labor is often the more expensive in the end, this depending la[...] upon the locality and the conditions imposed. Tables showing the approxi[...] cost of buildings of the MILL-CONSTRUCTION type are computed from the [...] of mill-buildings of light construction (cotton-mills with lateral beams [...] and are not adapted to computing the cost of heavy warehouses or si[...] factory-construction. The figuring of the cost of such buildings from the [...] PER SQUARE FOOT gives, at the very best, only approximate results; and [...] discrepancy of but 1 ct per sq ft will sometimes amount to thousands of do[...] the method is hardly accurate enough to estimate even the approximate c[...]

The Cost of Buildings of Mill-Construction in New England. [...] following eight buildings were designed by Lockwood, Greene and Com[...] of Boston, Mass., who submit data and descriptions of buildings of MILL-[...] STRUCTION with their COST PER SQUARE FOOT. These buildings are, with a [...] exception, situated within a limited area where cost of labor and mat[...] vary but little. The floor-loads vary from 75 to 150 lb per sq ft, and the [...] runs from $0.715 to $1.56 per sq ft. Considering the textile-mills only, [...] average cost is $1.038 per sq ft, while the average cost of all these buildin[...] $1.113 per sq ft.

† Farrot & Livaudais, Ltd., New Orleans, La.

A Cotton Spinning-Mill. This mill has an attached picker-house, office d dye-house wings, and was built in Rhode Island in 1911. The following the details of construction: main mill, four stories; size, 263.17 by 131.67 ft; o-story picker-house, 42.67 by 131.67 ft; one-story dye-house 55 by 85.67 brick stair-tank, and other towers; walls of hard bricks; plank and wearing-rs on transverse I-beam framing, supported by cast-iron columns, except five bays, where both transverse and longitudinal framing is used; slag roof-on plank on wooden transverse rafters; floors built for a live-load of 75 lb r sq ft. The cost of the buildings was $0.965 per sq ft.

A Four-Story Cotton-Mill. This mill is without basement. It was built, ther with the fan-room and repair-shop additions in Georgia, in 1910. The wing are the details of construction: mill, four stories; size, 272 by 128 ft; e and repair-shop, one story in height and 122.67 by 36 ft in plan; regular l-construction, that is, brick walls, hard-pine transverse floor-framing, wooden mns and plank floors, except for six bays of the fourth floor which have l I-beam longitudinals in addition to the hard-pine transverse timbers, and sixteen bays of the roof-framing which have both longitudinal and transverse d-pine timbers, these having been found necessary in both cases because of omission of the alternate columns. These buildings have extensive monitors, -tooth skylights, stair-towers, etc. The floors are designed to carry a live d of 75 lb per sq ft. The cost of the building was $0.715 per sq ft.

Cotton-Mill of Irregular Shape. This mill is considerably wider at end than at the other and has a basement at one end. It was built in sachusetts in 1911. The following are the details of its construction: mill, stories; length, 311.67 ft and average width, 75.42 ft; five-story wing, 6 by 40.01 ft, with extensive pent-houses; stair and elevator-towers and ights; brick walls, transverse wooden floor-framing, supported by cast-iron mns and brick walls; conditions at site demanded extensive foundations; dows in fourth and fifth stories of one wall protected by wire-glass in metal es; and floors built for a live load of 75 lb per sq ft. The cost of the buildings $1.172 per sq ft.

One-Story Machine-Shop. This was built near Boston, Mass., in 1910. main building is 200 by 136.375 ft with a connecting wing, 50 by 39.33 ft. s brick walls; longitudinal, steel, I-beam framing; transverse, steel, saw-h skylight framing; plank roof covered with tar and gravel; 20-ft longitu-l and 16-ft transverse bays; steel I-beam columns; 4½-in cement floors pt for three bays which have a 1-in maple overflooring, a 1-in North Caro-pine, intermediate layer, a 3-in kyanized spruce-plank layer, and 4½ in of oncrete; and extensive saw-tooth skylights. The cost of the buildings $1.288 per sq ft.

Building for Manufacturing Automobiles. This building has forge-extensions and was built in Connecticut in 1910. The main building our stories and a basement and is 54 by 151 ft in plan with a one-story sion, 50 by 149 ft, with extensive pent-houses and monitors. The factory-ng has brick walls, transverse yellow-pine framing on heavy wooden col-and on walls, floors of 1-in maple overflooring over 4-in yellow-pine planks, f of 3-in yellow-pine planks covered with tar and gravel, and a 4½-in t, basement-floor. The extension has brick walls; a brick-on-edge floor n a 4-in course of cement concrete on earth; steel roof-trusses, of 47-ft, pan placed 10 ft on centers; tar-and-gravel roof; and extensive monitors. oors are built to carry a live load of 125 lb per sq ft. The cost of the ng was $1.075 per sq ft.

A Two-Story Wooden Box-Factory. This factory has no basement. It was built near Boston, Mass., in 1909. In plan it is 155 by 305 ft and its average height is 32.5 ft. It has brick shafts; transverse wooden framing for the first floor; transverse beams supported by longitudinals for the second floor and roof; wooden columns and plank floors; and wooden monitors. The floors are designed to carry a live load of 150 lb per sq ft. The cost of this building was $0.84 per sq ft.

A One-Story-and-Basement Weave-Shed. This was built near Boston, Mass., in 1909. It is 213 by 244.17 ft in plan, with extensive entrances, towers and saw-tooth skylights. It has brick walls; longitudinal I-beam girders supporting transverse I-beam girders in the first story, resting on brick piers; transverse hard-pine girders supporting longitudinal girders for the saw-tooth skylight-framing; heavy, wooden floors and roof; wooden columns; an earth basement-floor; and foundations on concrete piles. The floors are designed to carry a live load of 100 lb per sq ft. The cost of the buildings, on the one-story basis, was $1.56 per sq ft.

A Two-and-One-half Story Picker-House. There is, also, a two-and-one-half story picker-house and a one-story connecting passage between the two buildings mentioned above for the cotton mill of irregular shape, which were built in Massachusetts in 1911. The picker-house is 64 by 95 ft in plan; the waste-house 21 by 4[illegible]; the covered bridge 10 by 40 ft; and the average height of the building 42.5 ft. The walls are of brick. The picker-house has transverse wooden framing supported by wooden columns and has plank floors. The waste-house wing has transverse, steel I-beam framing and no columns, and concrete-slab floors. The floors are designed to carry a live load of 75 lb per sq ft. The cost of the building, including plumbing, was $1.29 per sq ft.

The Cost of Buildings of Mill-Construction in Philadelphia, Pa., and Vicinity. The following five buildings were designed by Stearns & C[illegible] Philadelphia, Pa., who submit data and descriptions, with the COST PER SQUARE FOOT. These buildings are within a very limited area, being in or within [illegible] miles of Philadelphia, and are of somewhat heavier construction than [illegible] described above, the floor-loads varying from 120 to 150 lb per sq ft and the cost ranging from $0.86 to $1.23 per sq ft. The average floor-load is 132 lb and the average cost $1.02 per sq ft. The two spinning-mills mentioned are designed for average floor-loads of 120 lb and their average cost was [illegible] per sq ft.

A Chocolate-Factory. This was built in Philadelphia, Pa., on open ground. It has an ornamental exterior; walls of Sayer and Fisher bricks with terra-cotta trimmings, and a main building, 83 by 303 ft in plan and two stories in height. One section of the building, 60 ft in length, is three stories high. The story heights are 14 ft from top to top of floors. The floors are designed to carry a live load of 150 lb per sq ft. It has foundations of concrete; heavy plank floors on heavy timber-framing; a slag roof; all stairways and elevators in brick towers; and openings in division walls equipped with fire-doors. The cost of the building, excluding plumbing, heating, electric work, elevators, fire-protection and mechanical equipment, was $0.86.

A Four-Story-and-Basement Chocolate-Factory. This building was erected in Philadelphia, Pa. It is 44 by 130 ft in plan, with average story heights of 13 ft. It was built in a congested part of the city, between other buildings. The cost of underpinning and shoring the adjacent buildings is included in the cost given. It has plain brick walls; slow-burning floor-construction of heavy, wooden timbers, with finished flooring of maple; stairways and elev[illegible]

brick enclosures; and a slag roof. The floors are designed to carry a live d of 150 lb per sq ft. The cost of the buildings including plumbing, but luding heating, electric work, elevators, fire-protection and mechanical ipment, was $1.23 per sq ft.

Spinning-Mill. This building was erected in Philadelphia, Pa., on ground en and easy of access. Its exterior is of brick, without ornamentation. It 4 by 268 ft in plan, three stories in height, the stories throughout being 15 ft n from top to top of floors. The floors throughout are calculated to carry a e load of 120 lb per sq ft. It has walls of brick; a slow-burning floor-con-uction with finished flooring of maple; a slag roof; and stairways and ele-tors in brick enclosures. The cost of the building, excluding plumbing, ting, electric work, elevators, fire-protection and mechanical equipment s $0.93 per sq ft.

Spinning-Mill. This building was erected in Philadelphia, Pa., on ground n and easy of access. Its exterior is a plain brick design. It is 69 by 269 ft plan and three stories in height, the story-heights throughout being 15 ft from top to top of floors. The floors throughout are calculated for a live d of 120 lb per sq ft. It has brick walls with concrete foundations; a slow-ning floor-construction with a finished flooring of maple; a slag roof; all irways and elevators in brick enclosures; and all openings in division walls ipped with fire-doors. The cost of the building excluding the plumbing, ting, electrical work, elevators, fire-protection and mechanical equipment, s $1.07; and the cost of the building including the plumbing, heating, elec-al work, elevators and fire-protection, but excluding the mechanical equip-nt, was $1.34.

Clothing-Factory. This building was erected in Woodbine, N. J., on nd open and easy of access. Its exterior is of brick, without ornamentation. s 45 by 179 ft in plan and three stories in height. The basement is 10 ft in ght, and the other stories 12 ft in height from top to top of floors. The rs are calculated throughout for a live load of 120 lb per sq ft. It has walls rick; slow-burning floors with yellow-pine finished flooring; a slag roof; and tairways and elevators in brick towers. The cost of the building, exclud-heating, electrical work, fire-protection and mechanical equipment, but in-ing freight-elevators and plumbing, was $1.01 per sq ft.

he Cost of Buildings of Mill-Construction in the Middle West. following six buildings were designed by F. G. Mueller, Hamilton, Ohio, submits data and descriptions with the costs of buildings of heavier con-ction. The floor-loads vary from 200 to 300 lb and the cost from $0.62 0.96 per sq ft. The paper-mill at Taylorsville, Ill., is partly of concrete truction, and was built at a cost of $1.30 per sq ft. Exclusive of the last-ed building, the average floor-load is 230 lb and the average cost $0.805 q ft.

Addition to a Paper-Mill. This was built in Dayton, Ohio. It is a story brick building, 116 by 79 ft in plan. The first story is used for paper-ge and the second story as a finishing-room. The first floor is of cement cinder fill; and the second floor of 2¾-in yellow-pine planks with an over-ng of ⅞-in maple, supported by 8 by 14-in beams, 14 by 16-in girders and r 10-in wooden posts. The floors are figured for a live load of 200 lb per . The roof is supported by six steel trusses and 4 by 10-in wooden purlins, covered with 1¾-in sheathing and composition roofing. The foundations f concrete. The cost of the building, exclusive of the plumbing and heat-vas $0.75 per sq ft.

An Addition to a Foundry. This one-story, brick, foundry-building erected in Hamilton, Ohio, is 432 by 63 ft in plan, and has a one-story wi 86 by 46 ft in plan, and a one-story cupola-house, 28½ by 26½ ft in plan. has a wooden floor in the wing only and dirt floors elsewhere. It has conc foundations; a composition roof on 2¼-in sheathing, supported by 12 by 1 girders, 6 by 12-in beams and 6-in cast-iron columns; an elevator in the cup house; and all doors of tin-clad construction. The cost of the building $0.836 per sq ft.

A Paper-Mill. This was built in Monroe, Mich., and is a one-story-a basement brick building, 185 by 87 ft in plan, with an end-wing 234 by 35 It has heavy beam and girder floor-construction, designed to carry a live l of 300 lb per sq ft; concrete foundations and a basement-part, 130 by 87 It is designed for one paper-making machine and four beaters, has a composit roofing and one skylight over the boiler-room. The cost was $0.88 per sq ft

A Paper-Mill. This is an irregular-shaped brick building erected in Ken worth, La., and is 356 by 168 ft in plan. About one-third of it is two sto and the remainder one story in height. It has a heavy wooden, beam, gi and post-construction; a stone foundation on cypress-grillage footings; floors designed to carry heavy paper-making machinery with a live load 250 lb per sq ft. The cost of the building was $0.96 per sq ft.

A Warehouse. This is a one-story-and-basement brick building, erecte Hamilton, Ohio, and is 38 by 50 ft and designed for a live load of 200 lb pe ft. It has a cement floor in the basement; 10 by 14-in girders, 8 by 12-in be and 10 by 10-in posts supporting 3⅝-in flooring; 10 by 14-in girders and 1 round, wooden posts carrying 2¼-in sheathing and composition roofing. cost of the building was $0.62 per sq ft.

A Paper-Mill. This was built in Taylorsville, Ill., and has a main buildi two stories in height and 49 by 130 ft in plan; a one-story part, 138 by 8 in plan; and a one-story wing, 42 by 144 ft in plan. There is a basement u almost the entire building. The foundations are of concrete and there cement floors in the basement. The first floor is of reinforced-beam, gi and slab-construction, designed for a live load of 250 lb per sq ft; the sec floor of mill-construction, supported by cast-iron columns, 14 by 18-in woo girders and 12 by 16-in wooden beams; and most of the roof is supported steel trusses and wooden purlins. The second floor was designed for a live l of 150 lb per sq ft. There are extensive skylights, pent-houses, etc. The of the building was $1.30 per sq ft.

The Cost of Buildings of Mill-Construction in Toronto, Can The building described in the following paragraph was designed by Sproat Rolph, of Toronto, Canada, who submit data of a warehouse-building with floor-openings and windows and other outer wall-openings protected in approved manner, and erected at a cost of $1.12 per sq ft.

A Five-Story-and-Basement Seed-Warehouse. This was built Toronto, Canada, and is 111 by 140 ft 3½ in in plan. The floor-heights ar ft 1 in, and the total height is 66 ft. The floors are built of 2 by 6-in piece pine on edge and the bays measure 12 ft 5 in by 13 ft. The beams are of long- yellow pine, 14 by 18 in in section; the posts of similar material, varying f 8 by 8 in to 16 by 16 in; the walls are of hard, red bricks with gray stone ings; and the sashes and frames are of steel throughout. The building has t elevators in a brick-enclosed shaft and one staircase in a separate brick The floors are designed to carry a live load of 250 lb per sq ft. The c the building, exclusive of the heating and lighting, was $1.12 per sq ft.

…he Cost of Buildings of Mill-Construction in Northwestern Canada. …e following four buildings were designed by J. H. G. Russell, Winnipeg, …ada, and are warehouses of very superior, heavy construction, widely …rated in location, yet varying little in cost. The floor-loads used vary …m 300 to 350 lb, live load, per sq ft and the cost varied from $1.41 to $1.54 … sq ft. The average cost was $1.46 per sq ft.

A Seven-Story-and-Basement Warehouse. This was built in Winnipeg, …nada, and is 50 ft 6 in by 119 ft 9 in in plan. The floors are of 6-in spruce with …in maple overflooring. All floors are on heavy girders and columns; the …vators are in brick shafts; and the walls are of brick, except the first story …nt wall, which is of cut stone. The floors are designed to carry 300 lb per …ft, live load. The cost of the building, exclusive of the heating, elevators, …, was $1.46 per sq ft.

A Three-Story-and-Basement Warehouse. This was built in Winnipeg, …nada, and is 62 ft 6 in by 86 ft 6 in in plan. Heavy fir timbers were used for …ming. It has a 6-in fir-plank solid floor with ⅞-in maple overflooring; …rs and elevators in brick towers; brick walls with the openings in the rear … sides of the building protected. The floors were designed to carry a live …d of 350 lb per sq ft, and the cost of the building, excluding the heating, etc., …s $1.41 per sq ft.

A Warehouse. This is a six-story-and-basement building, erected in Saska…n, Canada, and is 50 by 112 ft in plan. The floors are of 6-in fir, with ⅞-in …ple overflooring, and are supported by heavy fir timbers. The building has …ck walls with a front of pressed bricks and cut-stone trimmings; some of the …nings are protected by wire-glass windows; and the stairs and elevators are in …ck shafts. The floors were built to carry 350 lb per sq ft, live load, and the …lding cost, exclusive of the heating, elevators, etc., $1.44 per sq ft.

A Five-Story-and-Basement Warehouse. This was built in Edmonton, …ada, and is 50 by 137 ft in plan. The floors are of 6-in fir with ⅞-in maple …rflooring. The building has brick walls and the front and one side wall …faced with pressed bricks with stone trimmings. It has the openings in …rear wall protected and the stairs and elevators are in brick shafts. The …s are strong enough for two additional stories and the floors are designed …carry 350 lb, live load, per sq ft. The cost of the building, exclusive of …ting, elevators, etc. was $1.54 per sq ft.

…he Cost of Buildings of Mill-Construction in Vancouver, Canada. … building described in the following paragraph was designed by Dalton & …leigh, Vancouver, Canada, who give data of a warehouse with floors designed …arry an average load of 500 lb per sq ft and costing $1.09 per sq ft. Although …heaviest timbers and the heaviest wall-hangers and beam-hangers were …l, and the floors built of the maximum thickness, the cost was extremely … This no doubt was partly due to the proximity of the timber and the …ities for transporting it by water.

Warehouse for the Storage of Heavy Hardware. This was erected …Vancouver, Canada. The main building has four stories and a basement, …is 85 ft 6 in by 115 ft 6 in in plan. The office-wing has four stories and a …ment and is 60 by 40 ft. There is, also, a four-story and half-length-base…t building, 38 by 120 ft, connecting with the two upper stories of the main …ling by means of a steel bridge 40 ft long. The walls above the basement …f hard-burned brick and the concrete basement walls and floors are treated …hydrolite. The main girders are set 23 ft on centers and vary in section …12 by 16 in to 18 by 24 in and are all one-piece sticks. The posts, set 11 ft

10 in on centers, vary from 12 by 12 in in one piece, to 20 by 38 in, in t pieces. The joists, set 4 ft on centers, vary from 8 by 16 in to 16 by 24 in in piece. The floors are made of 4 by 6-in and 4 by 4-in pieces, laid solid, top flooring made of 2 by 6-in, edge-grain, tongued and grooved pieces, two layers of asbestos between, weighing 10½ ounces per sq ft. All the bers are of fir. There are three brick-enclosed elevators with fire-doors, one elevator in a wooden shaft, built "solid" of 3-in. thick pieces. The of front is of pressed bricks and has plate glass, marble steps and copper t The windows are glazed with wire-glass in metal frames, and there are doors on the outer door-openings. The roof is made of a 6-ply composition a gravel coating. The live load used for the floors varied from 1 000 lb sq ft on the ground floor to 250 lb on the top floor, the average live load b 500 lb per sq ft. The walls and posts were designed to carry two additi stories, with a live load of 225 lb per sq ft. The cost of the building, exclu of the heating and office and warehouse-fixtures, was $1.09 per sq ft.

22. Cost* of Brick Mill-Buildings of Slow-Burning Constructio

Approximate Cost of Brick Mill-Buildings. Mr. C. T. Main† has ma series of diagrams showing the cost in New England, in 1910, PER SQUARE F OF FLOOR SPACE, of BRICK MILL-BUILDINGS of different sizes, from one to stories in height, and of the type known as SLOW-BURNING. The calculat are made for total floor-loads of about 75 lb per sq ft. The figures taken f the diagrams are given on the following page. The costs include ordi foundations and plumbing, but no heating, sprinklers or lighting.

Modifications of the Costs given in Table I: (1) If the soil is poor or conditions of the site are such as to require more than ordinary foundati the cost will be increased.

(2) If the building is to be used for ordinary storage-purposes with low st and no overflooring, the cost will be decreased from about 10% for la low buildings to 25% for small, high ones, about 20% being usually a allowance.

(3) If the building is to be used for manufacturing and is substantially b of wood, the cost will be decreased from about 6% for large, one-story build to 33% for small, high buildings; 15% would usually be a fair allowance.

(4) If the building is to be used for storage and built with low stories and stantially of wood, the cost will be decreased from 13% for large, one-s buildings to 50% for small, high buildings; 30% would usually be a fair al ance.

(5) If the total floor-loads are more than 75 lb per sq ft the cos increased.

(6) For office-buildings, the cost must be increased to cover the exte architectural treatment and the interior finish.

(7) Reinforced-concrete buildings, designed to carry floor-loads of 100 l less per sq ft will cost about 25% more than those of the slow-burning of mill-construction.

* These are pre-war prices, but the data are retained for purposes of compariso relative costs in the analysis made. For the cost of reinforced-concrete mills, wareho etc., see pages 1613 and 1618.

† Engineering News, January 27, 1910.

Table I. Cost of Brick Mill-Buildings per Square Foot of Floor-Area

Length in ft / Width in ft	50	100	150	200	250	300	350	400	500
					One story				
25	$1.90	$1.66	$1.58	$1.54	$1.51	$1.49	$1.48	$1.47	$1.46
50	1.52	1.29	1.21	1.18	1.16	1.15	1.14	1.13	1.13
75	1.41	1.21	1.12	1.08	1.06	1.04	1.03	1.02	1.02
125	1.32	1.09	1.02	0.98	0.96	0.94	0.94	0.93	0.92
					Two stories				
25	2.00	1.62	1.52	1.47	1.44	1.41	1.39	1.38	1.36
50	1.50	1.21	1.13	1.09	1.06	1.05	1.04	1.03	1.02
75	1.34	1.08	1.01	0.97	0.94	0.92	0.92	0.91	0.90
125	1.22	0.97	0.90	0.86	0.84	0.82	0.81	0.80	0.86
					Three stories				
25	1.98	1.57	1.47	1.42	1.39	1.38	1.36	1.35	1.34
50	1.47	1.17	1.07	1.03	1.01	1.00	0.98	0.98	0.98
75	1.30	1.05	0.98	0.94	0.91	0.89	0.88	0.87	0.86
125	1.18	0.93	0.86	0.82	0.80	0.78	0.77	0.76	0.76
					Four stories				
25	2.00	1.61	1.50	1.45	1.42	1.40	1.38	1.37	1.36
50	1.38	1.17	1.10	1.05	1.02	1.00	1.00	0.99	0.98
75	1.32	1.08	0.97	0.93	0.90	0.88	0.88	0.87	0.87
125	1.20	0.93	0.85	0.81	0.78	0.77	0.76	0.75	0.74
					Six stories				
25	2.10	1.72	1.57	1.51	1.48	1.46	1.44	1.43	1.42
50	1.53	1.21	1.12	1.08	1.05	1.04	1.03	1.02	1.02
75	1.35	1.08	0.98	0.94	0.92	0.90	0.89	0.88	0.86
125	1.22	0.96	0.86	0.82	0.79	0.78	0.77	0.76	0.76

e COST PER SQUARE FOOT of a building 100 ft wide is about midway between tha e 75 ft wide and one 125 ft wide; and the cost of a five-story building about mid between the costs of a four-story and a six-story building.

ditional Data for estimating costs of foundation-walls and other wall iven in the following table:

II. Cost of Walls in Brick Mill-Buildings of Slow-Burning Constructio

Number of stories	1	2	3	4	5	6
ndations, including excavations						
st per lin ft:						
Outside walls	$2.00	$2.90	$3.80	$4.70	$5.60	$6.50
Inside walls	1.75	2.25	2.80	3.40	3.90	4.50
k walls						
st per sq ft of surface:						
Outside walls	0.40	0.44	0.47	0.50	0.53	0.57
Inside walls	0.40	0.40	0.40	0.43	0.45	0.47

Columns, including piers and castings, cost about \$15 each.

Assumed Height of Stories: From ground to first floor, 3 ft. Build 25 ft wide, stories 13 ft high; 50 ft wide, 14 ft high; 75 ft wide, 15 ft h 100 ft and 125 ft wide, 16 ft high.

Cost of Floors: 32 cts per sq ft of gross floor-space, not including colun 38 cts, including columns.

Cost of Roof: 25 cts per sq ft, not including columns; 30 cts, incluc columns. Roof to project 18 in on all sides of buildings.

Stairways, including partitions, \$100 each flight. Include two stairways one elevator-tower for buildings up to 150 ft long; two stairways and two ele tor-towers for buildings up to 300 ft long. In buildings over two storie height, three stairways and three elevator-towers for buildings over 300 ft l

Plumbing Fixtures. In buildings of more than two stories figure \$75 each fixture, including the piping and partitions. Allow for two fixtures each floor up to 5 000 sq ft of floor-space, and one fixture for each additi 5 000 sq ft, or fraction thereof, of floor-space.

CHAPTER XXIII

FIREPROOFING OF BUILDINGS

By

RUDOLPH P. MILLER

SUPERINTENDENT OF BUILDINGS, NEW YORK CITY

1. Definitions, Areas, Heights, and Costs

Definitions. The term FIRE-PROOF, while now quite well understood by rchitects, is still used in a very broad sense by the public. To be strictly re-proof, a building must be constructed and finished entirely with incom-stible materials, and any of these materials, such as steel or iron, which are riously affected by heat or streams of water must be efficiently protected other materials which are not so affected. This precludes the use of wood, hether exposed or not exposed, also all exposed steel or iron, common glass, d most building stones. It is safe to say that there are very few buildings this country that are absolutely FIRE-PROOF. There are many, however, at could not be destroyed by fire, and in which the salvage would probably mount to from 60 to 80%; and it is the latter class which is generally meant hen the term FIRE-PROOF is used. Incombustible buildings, and buildings of oden construction protected to a greater or less degree from the flames, are metimes advertised as FIRE-PROOF; but such buildings should be considered erely as SLOW-BURNING. It is undoubtedly the duty of every architect to be ll informed concerning the fire-proof qualities of all materials that enter to the construction and finishing of buildings, and to know how to use these aterials to the best advantage. His choice and use of materials is then limited ly by the character of the building and the interests of his clients. It is ended to furnish this information in a concise manner in this chapter. The tional Fire Protection Association recommends the discontinuance of the m FIRE-PROOF, and the use of the term FIRE-RESISTIVE in its stead. The mer term is the one used in the building laws of all the larger cities.

Municipal Definitions. Municipal definitions as to what constitutes FIRE-OOF CONSTRUCTION have a great bearing on the construction of buildings thin their jurisdiction. None is entirely comprehensive and the detailed uirements must be consulted in each case. The Chicago definition is ical of most of them.

Chicago Definition.* "The term FIRE-PROOF CONSTRUCTION shall apply to buildings in which all parts that carry weights or resist strains,† and also all erior walls and all interior walls and all interior partitions and all stairways l all elevator enclosures are made entirely of incombustible materials, and in ich all metallic structural members are protected against the effects of fire coverings of a material which shall be entirely incombustible, and a slow heat ductor, and hereinafter termed FIRE-PROOF MATERIAL. Reinforced concrete

Quoted matter is left in its original form. The editor-in-chief is not responsible for syntax, punctuation, etc.

Stresses are meant.

as defined in this ordinance shall be considered fire-proof construction, wh built as required by Section 550."

When Fire-proof Construction Should be Employed. A building sho be designed, built, and finished to conform to the purpose for which it is to used. A building containing but little inflammable material, and that no great value, need not be as thoroughly fire-proof as one designed for the stor of valuable goods, or for the protection of life in case of fire. The height o building is an important factor in determining whether it should be fire-pr or not. The rate of increase in the difficulty of coping with fire in a build is greater than that of the increase in the height. The area covered by building, also, is important, although in most instances interior division-w may be provided which practically cut up a building into a series of sma buildings. Some of the limitations placed upon non-fire-proof buildings various municipal laws will be found in the following classification and in Tabl page 813.

Limiting Areas for Non-Fire-proof Buildings.

New York City,	7 500 sq ft on an interior lot.
	12 000 sq ft on a corner.
	15 000 sq ft when facing three streets.
Chicago, Ill.,	9 000 sq ft if of ordinary joisted construction.
	12 000 sq ft if of slow-burning construction.
St. Louis, Mo.,	7 500 sq ft.
Boston, Mass.,	10 000 sq ft.
Cleveland, Ohio,	Mill-Construction:
	20 000 sq ft when facing streets on four sides.
	15 000 sq ft when facing streets on three sides.
	12 000 sq ft when facing streets on two sides.
	9 000 sq ft when facing streets on one side.
	5 000 sq ft on any lot when of hazardous occupancy.
Cleveland, Ohio,	Ordinary Construction:
	12 500 sq ft when facing streets on four sides.
	10 000 sq ft when facing streets on three sides.
	7 500 sq ft when facing streets on two sides.
	5 000 sq ft when facing streets on one side.
	2 000 sq ft on any lot when of hazardous occupancy.

Cost of Fire-proof Construction. F. W. Fitzpatrick, found, previou 1903, that fire-proof construction for office-buildings, hotels, etc., adds fr 9 to 13% to the cost of ordinary construction with wooden joists. For st and warehouses the difference will often be less than 5%.* Walter F. Ballin stated (1909) that reinforced-concrete construction cost from 10 to 15% m per square foot of floor-surface than mill-construction and about 25% less th steel-frame and terra-cotta fire-proof construction.† Figures given by J. P. Perry (1911) indicated that reinforced-concrete construction added from 2 to 2 to the cost of mill-construction for commercial buildings, with an averag 6.7% for various localities and all classes of buildings in the United Sta The increase in cost of structural-steel fire-proof construction over reinforc concrete construction averaged 6.4% for fourteen buildings of all classes various localities.‡ More recent comparisons are not available, but it be safely asserted that the increased cost of fire-proof construction over m

construction and ordinary joisted construction is less than indicated by t figures.

Divisions of the Subject. In constructing fire-proof buildings it is ne sary to consider:

(1) Materials to be used.
(2) Form of construction.
(3) Protecting devices.
(4) Extinguishing appliances.

This general order is followed in the discussion of the subject in this chap

2. Fire-Resistance of Materials

Effect of Heat on Building Materials. All materials of construction more or less injuriously affected by high temperatures. Furthermore, an INC BUSTIBLE material is not necessarily FIRE-RESISTING, as, for instance, s The value of various materials in fire-proof construction is indicated in following paragraphs.

Brickwork. Common brickwork, when of a good quality, will stand expo to severe fire for a considerable length of time. Experience has shown t thick walls are less affected by heat than thin walls, and that hard-bur bricks stand better than soft or underburned bricks. In the Baltimore San Francisco fires, it was demonstrated that for outside walls brick is supe as a fire-proof material to any other material used in wall-construction.

Stone in General. Very few stones successfully stand the action of sev heat, and consequently stone in general should be used very sparingly in f proof buildings, and certain kinds of stone not at all.

Granite will explode and fly to pieces or disintegrate into sand when expo to flames.

Limestone and Marble are usually ruined if not totally destroyed by ordinary fire. They are the least desirable of all stones for use in a fire-p building, and the granites come next.

Sandstone when fine-grained and compact sometimes stands fire with serious injury, but in the case of a severe conflagration it is generally so ba affected that it has to be replaced.

Terra-Cotta is made from clay by mixing it with water into a plastic ma shaping the same into the form desired and baking it at a high temperature kilns. For the usual structural form the shaping is generally done by forc the plastic mass through a special die by means of machinery. Ornamen terra-cotta must generally be shaped by hand.

Ornamental Terra-Cotta. This material, and especially that which has glazed surface, is well adapted for the trimmings of a building that is intend to be fire-proof. It should, however, be made heavy enough to carry both own weight and its share of the wall-load.*

Structural Terra-Cotta. Terra-cotta, as used for floor-arches, column a girder-protection, and for building light, hollow walls, is made of three diffe ent compositions, the material being known as DENSE, POROUS, and SEI POROUS, according to the method of manufacture.

Dense Tiling is made from a variety of clays. Some manufacturers u

* Fire Prevention and Fire Protection, J. K. Freitag.

me or less fire-clay, and combine it with potter's clay, plastic clays, or tough ick-clay. It is very dense and possesses high crushing strength. In outer lls exposed to the weather and required to be light, it is very desirable. Some anufacturers furnish it with a semiglazed surface for the outer walls of build-gs. For such use it has great durability, and effectually stops moisture. In ing dense tilling for fire-proof filling, care should be taken that the tiles are e from cracks, sound, and hard-burned.

Porous and Semiporous Terra-Cotta is made by mixing sawdust with the y, the sawdust being destroyed by the action of the heat, leaving the material t and porous. A small proportion of fire-clay mixed with the plastic clay desirable but not essential. The proportion of sawdust should be from to 35%, according to the toughness of the clay used. Care is required in e process of manufacture to have the work of mixing, drying, and burning oughly done. The burning should be done in down-draught kilns, by a ick process. The product should be compact, tough, and hard, and should g when struck with metal. Poorly-mixed, pressed, or burned tiles, or tiles m short or sandy clays, present a ragged, soft, and crumbly appearance, and e not desirable. When properly made, porous terra-cotta will not crack or ak from unequal heating, or from being suddenly cooled with water when in heated condition. It can be cut with a saw or edge-tools, and nails or screws n be easily driven into it to secure interior finish, slates, tiles, etc. As a ccessful heat-resistant and non-conductor for the protection of other materials, must be ranked very high.

Semiporous Tiling. This material was introduced by those factories which e pure fire-clay in the manufacture of tile, to enable them to compete with e standard porous material. During the process of grinding the clay, about % of ground coal is mixed with it. This coal aids in the burning of the terial and also makes it lighter and more or less porous. Tiling made by s process is admitted to be a much better fire-resistant than the solid or se material. E. V. Johnson says: "personally, I believe that good semi-ous fire-clay tile is fully as efficient as a fire-resisting material as the standard kes of porous terra-cotta."

Strength of Terra-Cotta. (See, also, page 276.) In tests made at Columbia iversity for the building authorities of New York City on terra-cotta blocks en from material delivered in the open market, the following CRUSHING ENGTH was developed:

Table II. Crushing Strength of Terra-Cotta

Description of material	Position of cells in test	Compressive strength, lb per sq in	
		Gross area	Net area
ense tile	Vertical	1 864	4 721
	Horizontal	585	2 613
miporous tile	Vertical	1 027	2 168
	Horizontal	257	1 008

he inequality in strength of the two materials can be overcome by using ker webs and shells for the semiporous or porous material. In the matter

of WEIGHT, porous and semiporous terra-cotta have the advantage over de tile. Dense tiling, when heated and cooled by water, is liable to crack fi the sudden contraction; "blocks with two or more air-spaces are very li to have the outer webs destroyed under this action. Even if not cooled w water, other fires have shown that hard-burned terra-cotta will crack and to pieces under severe heat alone." * The experience of the recent confla tions in Baltimore and San Francisco fully bears out this statement. collapse of the floors of one of the buildings in Baltimore was largely due the weakening of the terra-cotta arches by reason of the breaking off of outer shells. Porous terra-cotta is non-heat-conducting in itself, and the b qualities will usually resist fire and water successfully; but if the product not burned at a sufficiently high temperature to consume all of the sawdust, throwing of cold water upon the heated surfaces will cause an expansion disintegration due to the absorption of the water and its conversion into stear Porous terra-cotta absorbs water freely, and if allowed to freeze when we more or less injured. If the process is permitted to continue, the blocks beco so weakened that they are unsafe for use.

Concrete Blocks and Concrete Tiles.† Numerous forms of building blo and tiles are manufactured of Portland-cement mortar or concrete for use substitutes for brick, stone, and terra-cotta. Concrete blocks are made the DRY PROCESS by tamping a dry-concrete mix into shape in forms, or by WET PROCESS which consists of pouring a semiliquid or SLUSH-MIX into mo and curing the product by air or steam. A third method, known as PRESSURE-PROCESS, is similar to the first, mechanical or hydraulic press being substituted for the tamping. Concrete hollow tile is being made the same uses as terra-cotta tiling, for partitions and floors in general, for enclosure-walls as well as for partitions in residences. For wall-bear purposes, the tiles are usually filled solid for a layer or two where the bea rest upon them. In hollow-block construction, distinction should always made between the strength of the blocks when laid with the core-holes verti and when laid with the core-holes horizontal, as the strength, in the lat position, approximates only one half of what it is in the former. The specifi tions of the American Concrete Institute, 1917, are generally accepted as best practice in the manufacture of concrete blocks. (See, also, Chapter I page 233.)

Concrete Tile. Concrete building tiles have been used for residences Chicago, Ill., Rochester, N. Y., and the suburbs of New York City. T shape and size of the blocks vary with the make of the product. In size shape they resemble terra-cotta tile, though the walls and webs are thic A WET-PROCESS tile was tested by the Bureau of Buildings, New York C in 1911, and showed a COMPRESSIVE STRENGTH in pounds per square in shown in Table III, page 817.

The Trout Concrete Tile Corporation of Flushing, N. Y., has develope method of making hollow tile whereby lightness is combined with streng The Trout tile is made in a hydraulic machine, with a pressure of 1200 lb each sq in of net area of the tile. While this pressure is being applied, particles of concrete are automatically moved about until the voids are fill and the result is a dense, hard product of even quality. This process perm the making of tile with thin walls, thereby reducing the weight to a minimu A tile 8 in high, 8 in wide, and 15¾ in long, with two cells, and with wa

nd webs 1 in thick, weighed 91.7 lb. Its compressive strength is given in e last line of Table III.

Concrete. Stone concrete, under the action of heat, is affected much the me way as brickwork The heated surface expands, and as the concrete is very poor conductor, the other surface remains cool and either cracks or uses warping. The heat also affects the strength and texture of the concrete, using a disintegration of the concrete to a depth of about 1 in. Often the rface spalls off with a report. If water is applied after the heat, the surface washed away to the depth of the affected part. These effects vary somewhat ith the stone used in the aggregate. Siliceous gravel has been found by tests d in actual fires to be very destructive to concrete. Granite, on account of e difference between its coefficient of expansion and that of the concrete, is ely to spall. Limestone calcines under the action of heat and is liable to struction for some depth by the water. Trap-rock is a satisfactory material use, from the standpoint of fire-resistance as well as that of strength. If ere is no application of water after the fire and the surface is allowed to cool gradually, the concrete may set again and become hard. It is not well wever, to rely on this. (See, also, Chapter III, page 245, for the effect heat on concrete fireproofing.)

Slag Concrete. Blast-furnace slag has been used as the aggregate in conte, with satisfactory results as to both fire-resistance and strength.* Care st be exercised in the selection of the slag. R. L. Humphrey says that y acid slag should be used and that it must be "dense, tough, and free m sulphur." Sanford Thompson states that the slag must be "air-cooled, shed, screened from dust, and free from foreign material," and that "exceptal care must be used in proportioning, mixing, and placing." †

Cinder Concrete. Cinder concrete, because of its porous character and the ture of its aggregate, makes an excellent fireproofing material. Tests and experience of conflagrations would indicate that it is the best. Care must, wever, be taken in the selection of the cinders. They must be clean furnaceders, free from unburnt coal. When properly selected and proportioned,

For a series of tests and description of materials, see pamphlet issued by the Carnegie l Company, 1911, Furnace Slags in Concrete. See, also, Proc. Am. Soc. for Test. ., 1914. A full discussion of slag concrete is published in the Iron and Coal Trade iew (London), for Nov. 22 and 29, 1918.

Engineering Record, March, 1917.

cinders produce good concrete, but generally a very non-homogeneous mate is obtained, so that its strength is variable and doubtful. If ground machinery before mixing, a better and more reliable concrete is produc In using cinder concrete in floor-construction the working loads are gener determined from load-tests and a high FACTOR OF SAFETY is used. The for practice in New York City was to take one tenth of the BREAKING-LOAD the WORKING LOAD. The building code now prescribes a formula for co puting the strength of cinder-concrete floors, within certain limitations.

Corrosive Action of Cinders. When cinder concrete is used to enc steel, either as a protective covering or as a part of a concrete construction, corrosive effect of cinders must be guarded against. A discussion of t subject will be found in Chapter XXIV, pages 960 and 961.

Mortars, Plasters, and Plaster of Paris. Mortar and plaster must nec sarily enter into the composition of all masonry buildings, whether built brick, stone, or terra-cotta. That ordinary lime mortar, when well made, endure for unlimited periods of time, in dry situations, has been proved actual use. Hydraulic-cement mortars are equally durable in wet or da places. For laying brickwork or tilework in first-class buildings, cement-an sand mortar is preferable to any other; and cement mixed with lime mor gives greater strength than lime and sand alone. Regarding the fire-pr qualities of mortars and plaster compositions there has been much controver the truth of the matter seems to be that all such compositions will withsta the action of heat up to a certain degree, when they are affected in one w or another, depending not only upon the composition but in large measure up their body, and upon the way in which they are used. Lime mortar for wa was formerly considered as the most satisfactory, so far as fire-resistance concerned; but since the improvements in cement-manufacture, cement mort is generally preferred. Lime plaster, applied on wire lath, will withstand a hi degree of heat without injury, but is liable to be washed away in places streams of water. Gypsum plasters, usually termed hard wall-plasters, patent plasters, when applied to brickwork or metal lath, are superior in he resistance to common lime, and the patent plasters will stand the combin effects of fire and water longer than the common mortars.

Plaster of Paris. Compositions of plaster of Paris (gypsum) and brok bricks, wood chips, or sawdust are non-conductors of heat and possess fir resisting properties of considerable importance; and on account of their ligh ness and cheapness, are often used in fire-proof or semi-fire-proof building In France such compositions have been used for generations to form ceilin between beams, and their durability and fireproofing qualities are unquestion in that country. Plaster of Paris compositions when subjected to severe he are softened on the surface, and when water is thrown upon them they wa away to some extent.

Asbestic Plaster. A plaster made by mixing Asbestic with freshly slack lime-putty has been used to some extent in New York City. Asbestic is ma from a serpentine rock, mined near Montreal, Canada, and contains a larg proportion of asbestos. "Claims of great fire-resisting properties are made f this material, as well as resistance to the effects of water during fire; crackin and discoloration due to the percolation of water or acids are also claimed to avoided. The plaster is tough and elastic, and it will receive nails withou chipping or cracking. The weight is said to about half that of ordinar cement mortar." Asbestic was subjected to a severe fire-and-water test i the presence of the officials of the Supervising Architect's office at Washingto D. C., "and the plaster did not crack or drop, but remained intact. All

walls, ceilings, and columns of the appraiser's warehouse in New York City were covered with a coat of Asbestic, from $\frac{1}{8}$ to $\frac{1}{4}$ in thick, applied on the concrete or terra-cotta surfaces. The great objection to the use of this material lies in its slow drying, the time required for a thorough drying out being usually very long." *

Asbestos-Products. Asbestos fiber combined with cement is manufactured in the form of steam-packings, corrugated sheathings, roof-coatings and shingles, wall-boards and building-lumber, insulating sheathing and blocks, asbestos theater-curtains, various forms of preservative and fire-resisting compounds, and substitutes for wall-plaster and stucco. The value of these products lies in their low heat-conductivity and incombustibility.

Asbestos Building Lumber is made in standard sheets, 42 by 48, and 42 by 96 in in size, and varying in thickness from $\frac{1}{8}$ in (about $1\frac{1}{4}$ lb per sq ft in weight) to 1 in (about $10\frac{5}{8}$ lb per sq ft in weight). When seasoned it is harder than ordinary wood, takes nails and screws, and it can be manipulated with heavy tools and machinery such as are used for working iron. It is too hard for ordinary wood-working tools. It is sufficiently elastic to withstand ordinary vibration, expansion, and contraction of surrounding parts, wind-pressure, and blows; and in large pieces, it can be bent around slight curves without splitting.

Asbestos Corrugated Sheathing is corrugated asbestos building-lumber, reinforced with sheet steel of from No. 24 to No. 27 United States gauge, or with open-wire netting. It is applied in the same way that corrugated iron is applied, either nailed to wooden strips bolted to the purlins, or clipped directly to the purlins by clips of hoop-iron or wire. It comes in standard sheets, $27\frac{1}{2}$ in wide and in lengths of 4, 5, 6, 7, 8, and 10 ft.

Asbestos Roofing-Shingles, suitable for wooden-roof construction, possess fire-resisting qualities far superior to wooden shingles. The advantages claimed are their fire-proof qualities, toughness, elasticity, and lightness in weight; ease of manipulation, cutting, sawing, and shaping to fit dormer windows, chimneys, etc.; and their immunity from the corrosive action of salt air. The principal companies manufacturing asbestos building-products are the Johns-Manville Company, New York City; the Keasbey & Mattison Company, Ambler, Pa.; and the Asbestos Manufacturing Company, Lachine, Canada.

Robertson Process Metal consists of steel sheets of from No. 26 to No. 20 United States gauge, enveloped in successive layers of an asphaltic compound containing heavy natural oils, an asphalt-impregnated asbestos-felt, put together under great pressure, and a patented water-proof coating. The sheets are made flat, corrugated, or beaded. It forms an incombustible roofing, siding, sheathing, and interior-finish material. The manufacture of this product is controlled by the H. H. Robertson Company, of Pittsburgh, Pa.

Steel and Wrought Iron. Wrought iron and steel will expand, bend, and twist under a moderate degree of heat. Inasmuch as a temperature of 1 700° F. is not unusual in fires, these materials should not be used in fire-proof construction without proper protection. Fire tests at the Continental Iron Works in 1896 showed that unprotected steel columns under load began to fail when the temperature reached about 1 100° F.† In the Baltimore and San Francisco fires there were many instances of failure in steel columns due to lack of or to insufficient protection.

Cast Iron. "As the result of tests and actual experience in conflagrations it may be stated that unprotected cast iron can stand practically unharmed up

* Freitag.

† See Engineeering News, Aug. 6, 1896.

to temperatures of 1300 or 1500° F. while carrying very heavy loads, even w frequent applications of cold water while the metal is at a red heat."* In tests at the Continental Iron Works, referred to in the preceding paragrap temperature of nearly 1300° F. was reached before the cast-iron columns bega fail. The contents of most mercantile buildings, when burning freely, wo probably generate a heat exceeding at times 2000° F. Consequently, cast- columns, when unprotected, are almost sure to fail in such a fire either by be ing or breaking. No building in which unprotected iron or steel columns used can be considered fire-proof; but in many classes of buildings unprotec cast-iron columns might safely withstand any heat to which they would prob be exposed. From a fire-resisting point of view, when there is no protec covering, cast-iron columns are unquestionably preferable to steel columns.

Fire-proof Wood. To meet the requirements of certain provisions of New York City Building Code, an attempt has been made to produce fire-p wood. The processes for rendering wood fire-proof, in general, consist in pregnating its fibers with certain chemicals. After the fireproofing-proc the lumber should be thoroughly kiln-dried before it is used. The softwo are more easily thoroughly treated than the hardwoods, the resinous wo being particularly difficult to handle.

"The treatment of the wood to render it fire-proof slightly raises the ignit point of the wood. The treated wood is harder to light than the untrea wood, taking two to three times as long to ignite. The amount of wood destro when exposed to the action of a flame is from 5 to 12 per cent greater in case of an untreated wood than in the case of a treated wood. The untre wood furnished more flame than the treated wood. The untreated wood sustain flame longer than the treated wood after the source of heat been removed. From this it can be seen that the fire-proofed wood is likely to ignite and less likely to cause the spread of fire than the untre wood."†

Among the disadvantages of fire-proof wood should be mentioned an incre difficulty in working the wood, and a tendency to dull woodworking-tools rapidly than with untreated wood. Hence an increased cost in the use of proof wood. The salts used in the process of fireproofing being hygrosc tend to keep the woodwork damp. Hardware or other metalwork in co with fire-proofed wood is liable to corrode. The strength of the wood is affected, and in some cases the wood becomes quite brittle. These two mentioned faults can be largely overcome by neutralizing the fireproo solution by a proper mixture of acid and alkaline salts.

The test, known as the timber-test, applied to fire-proof wood in New City, consists in placing a stick of the treated wood, ¾ by 1½ in in cross-se and 8 in in length, for two minutes over a crucible gas-furnace in which a stant temperature of 1700° F. is maintained; then removing the test-p noting the time it continues to flame and glow; and then scraping awa charred wood and determining the percentage of unburned wood. The ditions of acceptance are that, "the flame and glow should disappear w ten to twenty seconds after the removal of the test-piece from the furnace the unburned and uncharred section at the center of the specimen shou not less than 50 to 70 per cent of the original cross-section, depending o variety of wood under test." If the wood has been thoroughly treat splinter of it after having been exposed to flame and withdrawn, will

* Freitag.

† See Insurance Engineering, Vol. IV, page 551; also Professor Norton's B No. 1 to the Boston Manufacturers' Mutual Fire Insurance Company.

glow or flame. Other tests have been suggested and used but need not lescribed here.

Fire-Glass. The introduction of this material has made it possible to se fire-protection in many cases, without the necessity of disfigurement due re-shutters. Wire-glass is either RIBBED, ROUGH, MAZE, COBWEB, or POLISHED TE, with wire embedded in its center during the process of manufacture. The temperature at which the wire is embedded in the glass insures ad- on between the metallic netting and the glass, and the two materials become and inseparable, so that if the glass is broken by shock, by intense heat, or other cause, it remains intact." It is this property of remaining intact gives it its fire-retarding qualities. Although fire and water may cause ks to spread throughout the glass, the wire holds the pieces so firmly that es cannot pass through it. Many severe tests during actual fires have tively demonstrated the truth of the above claim. For warehouses and ries the RIBBED OR MAZE glass is generally preferable; but for offices, or ever clear transparent glass is desired, the POLISHED PLATE is nearly if quite as acceptable as the same glass without the wire, the effect being the as that obtained by looking through a window with a screen on the out- Where FIRE-RESISTANCE is the desired feature, the following requirements ld be satisfied. The thickness of the plate at the thinnest part should t less than ¼ in, and the plane of the wire mesh should be midway between wo surfaces of the glass. No wire should be smaller than No. 24 Brown arpe gauge. The unsupported surface of the glass should not exceed q in in any case and should be contained in a metal frame not larger than 9 ft between supports. The chief manufacturers of wire-glass in this coun- are the Pennsylvania Wire Glass Company, Philadelphia, Pa; the Mis- pi Wire Glass Company, New York; the Western Glass Company, Streator, and the Highland Glass Company, Washington, Pa. As now manufactured e continuous process, it is rolled in lengths up to about 10 ft and in thick- s up to ½ in.

sm Glass. Prisms installed for the purposes of increased light are usu- not contained in frames which are designed to withstand severe heat. dimensions of the unsupported electro-glazed panel should not exceed in either direction. The polished plate in prism-glass units should not d 4 in in either direction, with a minimum thickness of 3/16 in. In Report of the Insurance Engineering Experiment Station, C. L. Norton describes es of comparative fire-tests on electro-glazed Luxfer prisms, 0.35 in thick in square; electro-glazed plate, ¼ in thick and 4 in square; and ¼-in wire- The results of these tests indicate that the three materials, in sheets up by 30 in, are of equal value in FIRE-RESISTANT PROPERTIES and remain ctive operation up to the time when the temperature of melting glass is d. (See, also, page 1578.)

-proof Paint. Numerous so-called FIRE-PROOF PAINTS have been in- ed in recent years. When applied to woodwork they provide a more or fective protection against fire and may, for this reason, prevent the of fire. The following regulations regarding fire-proof paint were in the annual report of the Manhattan Bureau of Buildings, New York, 4.

The term FIRE-PROOF PAINT shall be understood to mean any prepara- ed to cover the surfaces of wood or other materials for the purpose of ing the same against ignition.

No fire-proof paint will be considered satisfactory unless it so protects od or other material to which it is applied that the same will not flame

or glow after having been subjected to the flame of a gasoline torch for minutes.

"(3) Before applying fire-proof paint to any material the surfaces must cleaned.

"(4) Application of fire-proof paint must be repeated whenever it is fo that the material to which it is applied is no longer protected to fulfill Spe cation No. 2."

8. Column-Protection

Girder and Column-Protection. As the columns and girders of a build form the BACK-BONE of the structure, it is of vital importance that they be thoroughly protected from heat. As a rule, the manner of protecting th structural elements depends quite largely upon the floor-system adop Where concrete is used for the floor-construction it is generally also emplo for incasing the columns and girders; where hollow tile is used in the floors, same material is almost invariably employed for protecting the steel fra The methods used for protecting girders are described in Subdivision 4 of chapter. (See, also, pages 780 to 782.)

Necessity for Column-Protection. It is now generally recognized that and steel columns should be incased with some material that will thoroughly tect the metal against fire. In 1896 a committee of the American Society Mechanical Engineers, in conjunction with representatives from other organi tions, made a series of fire-tests on full-sized unprotected cast-iron columns steel columns, loaded to their figured safe capacities. These tests showed the steel columns failed at an average temperature of 1 150° F., and the c iron columns at an average temperature of 1 300° F., the failure setting in a an exposure to the fire of from 23 minutes to 1 hour and 20 minutes, or average duration of about 50 minutes. In order to determine the value several materials as satisfactory protective coverings, the Bureau of Buildi

Table IV. Tests of Protective Coverings

Materials under test	Temp. on face of protective material, degrees Fahr.	Temperature of plate at back of protective material, degrees Fahr.		
		Before heating	After heating for 2 hr	Heat trans-mission
Terra-cotta: dense, hollow, 2 in thick..	1 700	75	223	148
Terra-cotta: semiporous, solid, 2 in thick	1 700	73	244	171
Plaster of Paris and shavings, 2 in thick	1 700	69	159	90
Plaster of Paris and asbestos, 2 in thick.	1 700	70	163	93
Plaster of Paris, wood fibers, and infusorial earth, 2 in thick	1 700	72	167	95
Concrete of ground cinders, 1 3/16 in thick	1 700	73	363	290
Cinder concrete, on metal lath, 2 in thick	1 700	66	248	182
Metal lath and patent plaster, about ½ in thick over 1 in air-space	1 700	76	296	218

ʏ York City made a series of tests on the HEAT-CONDUCTIVITY of these als. A cast-iron plate covered with the material under test was subjected mperature of 1 700° F. for two hours over a crucible furnace, and the the plate noted at regular intervals of time. The results of the tests are in Table IV on page 822.

Figs. 2, 3, and 4 show common methods of protecting cylin-olumns, and Figs. 5 and 6 columns of rectangular cross-section. The ard, shown in Fig. 1, is often employed in mercantile and manufacturing gs and put on to a height of 4 or 5 ft above the floor. The efficiency of struction is greatly increased by wrapping the columns with wire lath plastering, although it is not a common practice. To insure the protec-the metal under the most trying conditions, it is imperative that the

Solid-tile Pro-n. Cylindrical mn

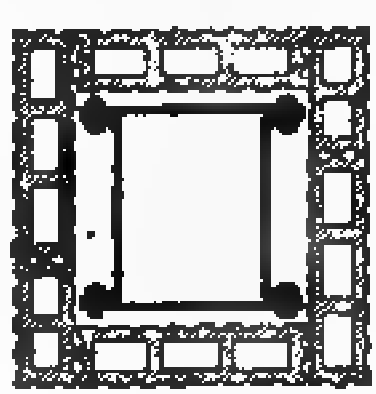

Fig. 5. Hollow-tile Protection. Built-up Box Column

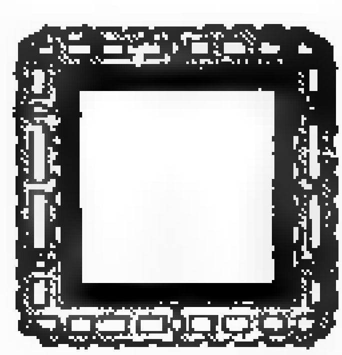

Fig. 6. Hollow-tile Protection. Square Column-section

protective covering shall not be detached by the streams from the firem hose, and thus expose the steel. This can be positively guarded against by using two layers of tiling or concrete and wrapping the inner layer metal lathing. Fig. 7 shows a column protected in this way, the construc being essentially that adopted in the Fair Building in Chicago, Ill. inner layer of tiles is wrapped with wire lath embedded in the mortar, and spaces between the and metal are f solid with cement m tar.

Concrete Colu Protection. W concrete is to be for column-protec the way to obtain most efficient const tion is undoubted surround the metal cinder concrete, po inside of a plank f set around the colu a coat of liquid ce being first applied a brush to the m The plank form sh be set at least 2 in side of the metal. It is generally conceded that this forms one of the m efficient fire-casings for columns, and, in addition, lends added stiffness to the members embedded in it. It is advisable to reinforce the concrete or anchor i

Fig. 8. Concrete Column-protection and Wooden Form

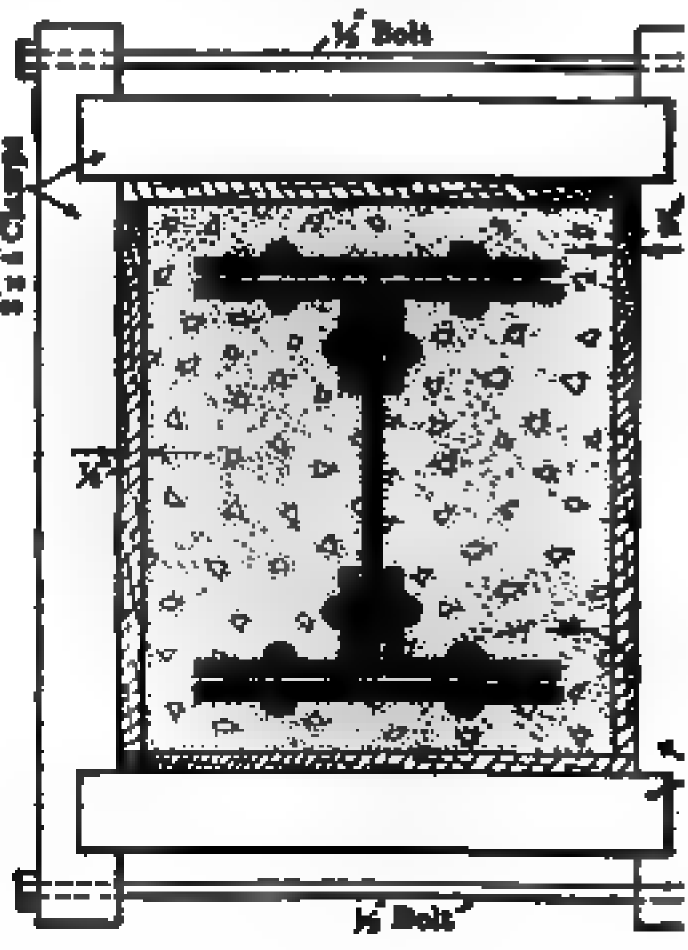

Fig. 9. Concrete Column-protection Wooden Form

ms of metal lath to the steel column. There are two general methods in in applying the concrete. Fig. 8 illustrates a column which is first wrapped ally with No. 10 gauge galvanized wire, 12 in on centers, to afford a key the concrete. The wood forms are placed the full length of the column, the concrete poured from a hole in the ceiling above. A slush-mixture of r cinder or stone concrete of 1 : 2 : 5 mix may be used. Fig. 9 shows a form ugh boards, made in sections from 4 to 6 ft in length and provided with s at each end. The concrete may be thoroughly tamped about the column ach section is placed and filled. Fig. 10 shows a method of furring the m with stiffened wire lath, which serves as a substitute for the wooden s and at the same time anchors the concrete to the steel. A similar

Furring

Concrete Column-protection. Wire-lath Furring

Fig. 11. Metal-lath and Plaster Column-protection

l may be employed to obtain an air-space by placing immediately the column an envelope of metal lath with a 2-in layer of concrete. y buildings with reinforced concrete floors, the columns are protected by plaster on metal lath. When only a single covering is provided, tection cannot properly be considered fire-proof; but when two cover- provided, as in Fig. 11, they are probably all that is necessary for cast lumns. The greatest defect in lath and plaster for fireproofing is that ter is liable to be dislodged by the force of the water from the firemen's When there are two coverings, however, this danger is reduced to a mini- (See, also, Chapter XXII, Figs. 23, 24, and 25.)

er Column-Covering. Plaster-blocks have been used in buildings as n-covering, but their use is not to be recommended While it is true ir NON-CONDUCTIVITY is in their favor, it is difficult to secure them They are easily washed away by hose-streams and subject to greater than other materials. In unimportant work their cheapness may, at stify their use.

ction of Connections between Columns and Girders. The most parts of the coverings of columns, whatever the materials used, are those about the connections with the beams and girders. Concrete edly is better adapted for covering these parts of the column than any terial, because, being elastic, it can be made to fit into any space and ny form of connection.

The Cement-Gun. During recent years, a new method of prote structural steel by means of the CEMENT-GUN has been introduced. This consists essentially of two superimposed tanks, forming two compartm from the bottom of which a dry mixture of sand and cement is ejected by pressed air through a hose-line with a nozzle at the end. To this nozzle a s hose delivers a supply of water under pressure, which is applied to the dry stituents just before they emerge from the nozzle. The mortar issuing in form of a spray shoots out from the nozzle with considerable force and pinges on the surface of the steelwork. The columns of the fifty-five-s Woolworth Building in New York City are provided with a 1½-in coatin cement mortar applied in this way, and coated on the outside with a thickness of terra-cotta. The steelwork, also, of the new Grand Central minal Buildings in New York City are protected with a 2-in coat of ce mortar or Gunnite. By this means, inaccessible corners are readily prote without the use of forms. Tests have shown that Gunnite is superior in te and compressive strength, permeability, absorption, porosity, and adhesi good hand-made products of the same kind.*

Recesses for Pipes. "As a matter of economy, both in original cost in the matter of space, it has been the common practice to run water-p waste-pipes, and vent-pipes immediately alongside the steel columns and in the fire-resisting covering."† This is undoubtedly bad construction, as Fre

FIG. 12. Tile Column-protection with Pipe-space

FIG. 13. Concrete Column-p tion with Pipe-space

illustrates by explaining its disastrous results in recent conflagrations; a the better types of fire-proof buildings, the pipe-space is now separated fro columns by the fireproofing. Fig. 12 shows a method of running the in some fire-proof buildings, and it is probably as satisfactory as any arr ment in which the pipes are to be run beside the columns. Fig. 13 sho somewhat similar method in which concrete, metal lath, and plaster are ployed for the fireproofing.

4. Fire-proof Floor-Construction

Fire-proof Floors. In the study of fireproofing-materials by far the est attention has been given to FLOOR-CONSTRUCTION; and of the very number of types which have been developed, the characteristic and le ones are here considered.

* Engineering News, 1912, Vol. 67, page 26; and Vol. 68, page 1086.
† Fire Prevention and Fire Protection. J. K. Freitag, page 374.

lequirements for a Fire-proof Floor. It goes without saying that a fire-
f floor must be made of incombustible materials. It seems unnecessary,
, to mention that it must resist as much as possible the transmission of
; so as to afford thorough protection to the metal incased by it or forming
ssential part of it. The materials used should not disintegrate or otherwise
when exposed to heat or flame. They should also resist the action of water
may be used to extinguish a fire. The floor-construction should be essen-
y water-tight, so as to prevent damage by water in stories below. It should
esigned to safely carry its load at all times. The New York City Building
: describes certain acceptable forms of fire-proof floors, but also provides for
cceptance of other forms which successfully meet the prescribed fire and
gth tests. Fully eighty tests have been made under the auspices of the New
City authorities and these, together with a few made by the authorities of
cities, comprise practically all that have been made in this country. The
h Fire-Prevention Committee of London has also made a number of such
s*

e Tests for Floors. The STANDARD FIRE TEST of the American Society
esting Materials† is essentially the same as that required by the New
City Building Code and as the one used by the British Fire Prevention
nittee. Briefly, the New York test consists in subjecting the floor in ques-
carrying a load of 150 lb per sq ft, to a fire maintained at 1700° F. for four
; and then in applying a stream of water, at 60-lb nozzle-pressure, for ten
es, the floor being considered satisfactory if there has been no appreciable
oration due to the test and if it has resisted the passage of flames during
st.

es of Floor-Constructions. In considering the several systems of floor-
uction, they are for convenience divided into the following types or
:

(1) Brick arches,
(2) Terra-cotta or tile floors:
- *a.* Segmental,
- *b.* Flat side-construction,
- *c.* Flat end-construction,
- *d.* Reinforced-tile arches,
- *e.* Guastavino,

(3) Concrete floors:
- *a.* Segmental,
- *b.* Flat reinforced floors,
- *c.* Sectional systems,

4) Gypsum floors,
5) Metal-lumber-construction.

Floor-Arches. The first attempt at fire-proof floor-construction
wrought-iron beams was made by using BRICK ARCHES sprung between
ns and resting on the bottom flanges, as illustrated by Fig. 14. When
n of construction is used the bricks should be hard, well-burned bricks,
r bricks of good shape, laid to a line on centers without mortar, with
er edges touching; and all the joints should be filled in with cement
The bricks of one line should break joints with those of the next adjoining,
ase there is more than one row, the joints of one row should also break

ist of these tests made in the United States and in London, see Proc. Am.
est. Mats., Vol. VI, page 128.
ear Book, Am. Soc. Test. Mats.

joints with those of the row above or below. The arches need not be over 4 thick for spans between 6 and 8 ft, provided the haunches are filled with a g cement and gravel concrete, put in rather wet. The RISE of the arch sho be about one-eighth the span, or 1½ in to the foot; and the most desirable s

FIG. 14. Brick Floor-arch

is between 4 and 6 ft. The building laws of many cities provide that when spans exceed 5 ft the arches must be increased in thickness, generally to 8 The HAUNCHES should be filled with concrete, level with the top of the a In first-class fire-proof construction the bottom flanges of the beams should protected by terra-cotta SKEWBACKS, as in Fig. 15 which shows the construc

FIG. 15. Brick Floor-arch. Government Printing Office, Washington, D. C.

used for the floors of the principal stories of the Government Printing Offic Washington, D. C.* A 4-in brick arch of 6-ft span, well grouted and levele with Portland-cement concrete, should safely carry 300 or 400 lb to the sq foot. Experiments have shown that brick arches will stand very severe po ing and a great amount of DEFLECTION without failure. The WEIGHT of a f such as is shown in Fig. 14, is about 40 lb per sq ft, without the concrete f finish. TIE-RODS, as described on page 865, should always be provided. brick arch is the strongest type of arch for the span it occupies, with the ex tion, perhaps, of the stone-concrete arch. It is perhaps, also, the most expen Its weight necessitates a heavier framework than is required for other t and, on account of its appearance, it is adapted only to buildings of the wareh type.

Terra-Cotta or Tile Floor-Arches. TERRA-COTTA OR TILE as a fire- material, and the relative merit of dense, porous, and semiporous tile have discussed on page 815. For floor-construction the semiporous tile is prob the best as it is a compromise between the advantages and disadvantages o dense and porous tile, particularly as to strength and fire-resistance. As

* A description of the structural features of this building may be found in the Eng ing Record for Dec. 6, 1902.

d on page 827, five different types of terra-cotta floor-construction, including ger number of systems, will be discussed. For these a great variety of es and sizes of blocks, of the dense, porous, and semiporous material, are afactured in this country. The largest company devoted to the manu-re and erection of hollow-tile fireproofing-material is the National Fire fing Company, New York and Chicago. Another large company is Henry er & Son, New York. Any one of the large companies can make any of blocks desired, except such as are covered by letters-patent, and, as a they can make them in dense, porous, and semiporous material.

lvantages of Tile Floor-Arches. Many architects prefer the use of A-COTTA ARCHES in buildings because the setting of them causes less dis-ance to the mechanics of other branches of the construction. During the ng of CONCRETE ARCHES the continual dripping of water and bits of con-interferes seriously with other work. The work of installing tile arches erally more rapid than for other types and it is not necessary to wait for to dry out. The quality of terra-cotta can be readily judged from its rance, not only before it is put in place but also after it is set. Thus it does equire the constant supervision necessary for materials that are mixed y are put in place.

advantages of Tile Floor-Arches. The principal DISADVANTAGE OF ARCHES for floor-construction is the difficulty of adapting any system to ling of irregular-shaped spaces. The arches must be set between I beams nnels, and to get the best effect the supporting beams must be parallel or so. Tile arches, especially of the END-CONSTRUCTIONS, are weakened by holes for pipes than are the monolithic floors. As there is no bond en the rows of tiles in the END-CONSTRUCTION arch, if a single tile in a row out or omitted, there is nothing to hold up the remaining tiles in the row the adhesion of the mortar in the side joints. In this respect SIDE-D arches have an advantage over the END-CONSTRUCTION. Where it is ary to use considerable concrete filling over the arch the weight of the onstruction will usually greatly exceed that of the concrete systems, and lditional weight means, also, additional expense. The floor-blocks are o breakage and chipped blocks in the floor are not unusual.

ection of Floor-Arches. Flat arches of hollow tile require close INSPEC-uring erection to see that broken or imperfect tiles are not used; that s in END-CONSTRUCTION tiles abut opposite each other; that all joints perly mortared and that all of the steelwork is properly protected. Much orkmanship has been allowed to pass in order to avoid delay, and also it cannot be discovered until the centering is removed. A tile arch ly looks better on the top surface than it does on the bottom.*

ing of Tile Floor-Arches. Tile arches are always SET on wooden s suspended by bolts hooked over the tops of the I beams. For all spans and over, the centers should be slightly CAMBERED. Before any floor-are set, all girders projecting below floor-beams should be completely on the bottom and sides, independently of the floor-construction. To the steel from rust it should have a good coat of Portland-cement mortar he tiles are applied. After the centers are in place the beam-tiles should d under the bottom of the beams and mortar slushed on the sides. The ides of the SKEWBACKS which rest against the floor-beams should then ed with just enough mortar to give them a perfect bearing, and shoved

* areless workmanship possible in the setting of tile arches was clearly set forth cle in Engineering News, April 14, 1898.

up against the beams. After this, the INTERMEDIATE BLOCKS, with their r on one end and one side covered with a full bed of mortar, should be shov into place. The KEYS* should have mortar on both sides and one end, if sn METHOD KEYS are used, and they should fit snugly, but not tight. "Under no c ditions should a key be rammed in place. It is better to use a smaller key and out the space left with either a solid slab of tile, or, if the opening is too sm with a piece of slate."* "In setting tile arches it is very common to build arches in STRING-COURSES, first fitting all the skews, then all the intermediat and finally all the keys. This is bad practice, as it loads the center, both pla and stringers, to excess, causing too great a deflection. In the END-CONSTR TION the arches should be built one by one, each being complete before next is started. In SIDE-CONSTRUCTION, where joints are broken longitu nally, the arches should be keyed up or completed at the first point where intermediates meet the lines of the key, thus completing the successive arc as rapidly as possible."† All JOINTS in the arches should be filled with mort especially at the top.

Wetting the Floor-Tiles. In warm weather all hollow tiles, whether de or porous, should be well wet or water-soaked before laying. In freezing weat they must be kept dry.

Mortar for Setting Floor-Tiles. "Mortar for setting porous hollow should never be made of cement and sand alone, as such mortar is too SHO rolls off the tile, and does not insure a full joint."* A good mortar is m by mixing the cement and sand in the proportion of 1 : 3, and adding c lime putty or hydrated lime to the extent of 10% of the cement-content. T mortar should be thoroughly worked. Hot lime mortar should never be us In dry weather the centers can be removed in 36 hours after the tiles are in pl but it is much better to allow 48 hours and even longer in cold or wet weather

Filling above Tile Floor-Arches. The strength of all tile arches is grea increased by wetting their top surface and covering it with a rich cinder c crete, mixed with Portland cement, well tamped and brought level with tops of the steel beams. If the floors are to be finished in wood, NAILING-STR are required to secure the flooring. These nailing-strips are usually dove shape in cross-section, about 2½ in wide at the top, 3½ in at the bottom from 1¾ to 2 in thick. It is preferable to lay them at right-angles to the s beams, so that they may be secured to the top flanges by metal clips, as in Fig.

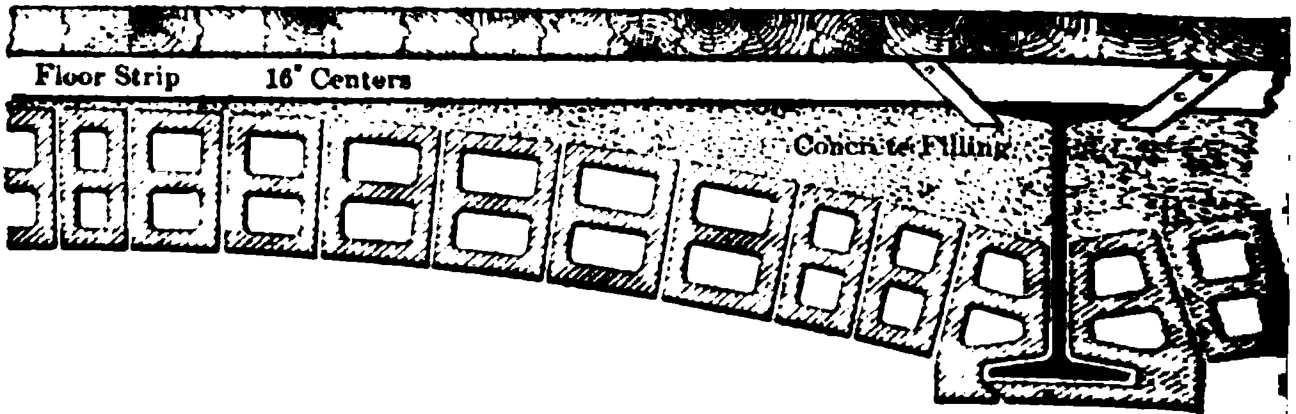

Fig. 16. Segmental Tile Floor-arch

Before the nailing-strips are laid, all piping and wiring which must go or through the tile arches should be put in place. After the nailing-stri in place the tops of the steel beams should be covered with a thin coat of

* E. A. Hoeppner. † Freitag.

d-cement-and-sand grout, applied with a brush. The spaces between the ing-strips should be filled with a 1 : 8 or 1 : 10 cinder concrete, finished ut ½ in below the tops of the strips. Some architects claim better results i strips of rectangular section, with nails driven horizontally into the ver-l sides to form the grip in the concrete. This method avoids the loosening e strips and flooring from any shrinkage of the strips.

le Filling-Blocks. In cases where the tops of the tile arches are 2 in or e below the tops of the steel beams, hollow tile blocks are sometimes used illing to the top of the beams, as in Fig. 23. These blocks are lighter than concrete, but they do not strengthen the arches.

ment Floors. If the floors are to be finished with cement, the cement and rete should be at least 2½ in and preferably 3 in thick above the steel beams, hould be blocked out in sections of not over 6 ft square, with joints extend-hrough the concrete. When practicable the joints in one direction should er the beams.

ather-Protection. Terra-cotta arches should always be protected against r snow, especially in freezing weather, as both the blocks and the mortar e joints are injured by freezing. Porous terra-cotta, especially, may be y ruined by freezing when soaked with water.

tection of Ceilings from Stains. "If plastered ceilings are to be used, rra-cotta work should be protected against the smoke or soot from the g-engines. Stains are also quite liable to occur from the effects of iron clay, or from the cinders in the concrete over the arches, if the floor is d to become wet."* To prevent these stains several kinds of hydraulic have been used, some of which have proved very effective.

mental Tile Floor-Arches. "This form of arch is the strongest and st. It is particularly adapted to warehouses, lofts, factories, sidewalks, ever great strength is required and a flat ceiling is not necessary. When strong arch is required in deep beams and a flat ceiling is also demanded, sult can be obtained by using a metal-lath ceiling suspended below the ."† These arches are usually formed by either 6 or 8-in hollow tiles, the SIDE-CONSTRUCTION principle and bonded endwise like a brick vault.

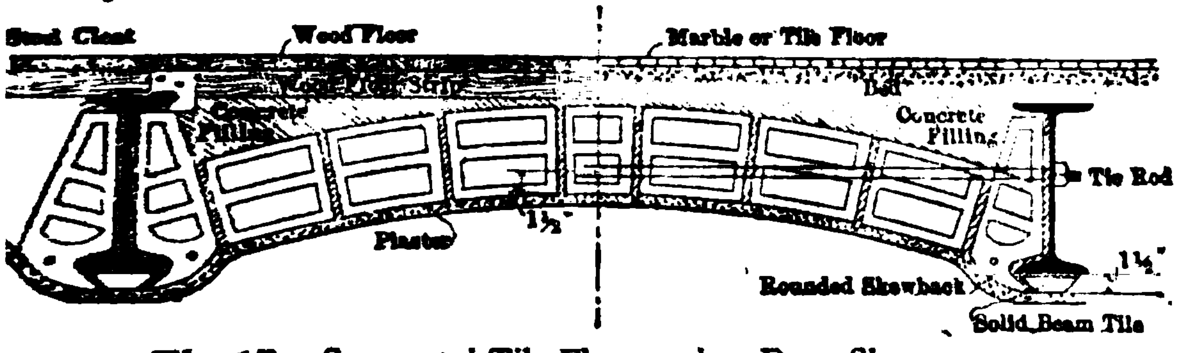

Fig. 17. Segmental Tile Floor-arch. Deep Skew

n be used for spans up to 20 ft, but it is better to limit the span to ; ft. "END-CONSTRUCTION blocks may be used, but they are unsatisfac-less the arches are of uniform span and rise throughout. The rise of -CONSTRUCTION arch can be varied by increasing the thickness of the lower part of the mortar joint, but this cannot be done with the END-CTION method."†

* Freitag.
† Bevier, National Fire Proofing Company, New York City.

Figs. 17 and 18 show typical forms of SEGMENTAL ARCHES. The w
of the arch-tiles will run about 26 lb per sq ft for 6-in tile and 32 lb for

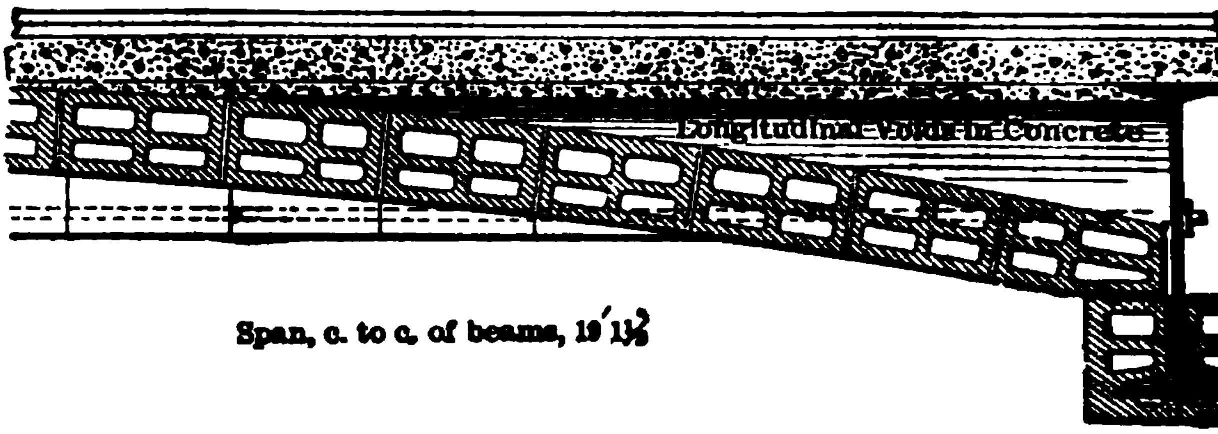

Fig. 18. Segmental Tile Floor-arch. Deep Beam. Dropped Skew

tile. To these weights should be added the weight of concrete filling, floo
plaster, etc.

Thickness of Webs. "For general use the WEBS of segment-tile shoul
½ in thick for semiporous tile and ¾ in for porous tile. The SKEWBACK sh
be at least ¾ in thick for the first-named material and 1 in for the second.
printing-establishments or any other building where a large amount of v
tion occurs the webs of all tiles must be designed in proportionate thickn
the load they are required to carry."* These thicknesses apply to Ch
practice more particularly, where a stronger tile is produced than in the East,
New York City webs are generally ⅝ in thick for semiporous and 1 in for p
tiles.

Rise of Segmental Floor-Arches. The RISE of the soffit of the arch a
the springing-line should be from one tenth to one eighth the span. The gr
the rise the less will be the THRUST of the arch. No single-cell tiles s
ever be used in any form of terra-cotta arch-construction.

Filling the Haunches. The HAUNCHES of SEGMENTAL ARCHES shou
filled with good cement concrete-leveled up to a point not less than 1 in
the CROWN of the arch. For short spans cinder-concrete filling may be
but for wide spans it is better to use gravel concrete, as the concrete
contributes to the strength of the arch at the haunches.

Tie-Rods. The THRUST of segmental arches is very considerable, so t
is important to provide TIE-RODS between the beams. A formula for dete
ing the STRESS in the tie-rods and their diameter is given on page 865.
most effective the tie-rods should be placed at the center of the skew. P
the tie-rods in this manner, however, may cause them to project belo
SOFFIT of the arch, giving an unsightly appearance to the ceiling. It i
more difficult to protect them when in this position.

Strength of the Segmental Semiporous-Tile Floor-Arches. Th
LOADS per square foot on 6 and 8-in segmental arches, with side-constr
semiporous tile, a rise of one-eighth the span, webs and shells ⅝ in thic
with a factor of safety of 7, as obtained from the tables of the Nation
Proofing Company are given in Table V.

Side-Construction Tile Floor-Arches. By this term is understo
flat-tile arches in which the voids in the blocks run parallel with the bea

10	443	529	....	....	....

e loads include the weight of construction; so that to get the safe live load, all
d load of arch-blocks, concrete fill, plastering, flooring, etc., must be deducted.

EAKING OF JOINTS that is effected in the setting of the blocks, by means ch the failure of a single block does not impair the strength of the arch l that block. The WEBS should not be less than 5/8 in thick. "RADIAL are sometimes specified but should be avoided, as they incur needless e in manufacture and endless confusion and delay in setting, without any

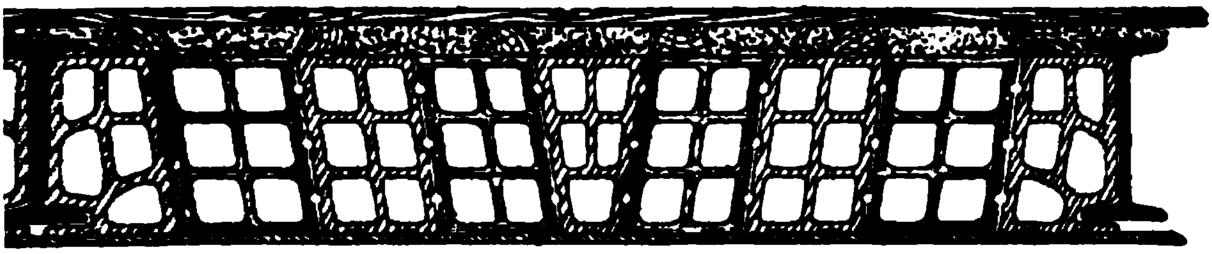

Fig. 19. Flat Tile Floor-arch. Side-construction

sating advantage." * In the SKEWBACKS a web should always be pro- cross the block at the lower flange of the beam, as at this point comes atest pressure in this block. Arches have collapsed because of failure ide this web. The DEPTH of the arch must be proportioned to the span the beams and to the load to be carried. For ordinary loads, a safe o make the depth of the block 1¼ in for each foot of span, plus the necessary for protection below the beams. SAFE LOADS for semiporous- es, side-construction, with webs 5/8 in thick and a factor of safety of 7, by the National Fire Proofing Company, are shown in Table VI.

Construction Flat Floor-Arches. In this construction the sides and the individual blocks run at right-angles to the beams, so that the pres- he blocks is endwise of the tile. It has been conclusively demonstrated low tiles are much stronger in END-COMPRESSION than transversely. jection urged against this construction is that it is wasteful of mortar cult to get the edges of the blocks properly bedded. They do require nore mortar, but the second objection is not serious, for, if the blocks o a proper bevel, the tighter they are set the stronger the arch."* The l blocks in the END-CONSTRUCTION are commonly made rectangular advancing by 1 in from 6 to 15 in in depth. The length and width, he blocks may be varied, but the standard size is 12 in for both dimen- he number of partitions or webs in the blocks varies with the size of

7 0	....	....	....	....	....	17

These loads represent the GROSS LOADS; so that for the SAFE LIVE LOADS the w of the construction, including the arch-blocks, fill, flooring, plastering, etc., mu deducted. For blocks with thicker webs the loads may be increased proportiona Where no loads are given in the table, the spans are considered excessive fo depth of block specified. The weights of arch given in the table are for the lig blocks. If thicker webs are used, the weight of block must be taken proportion greater.

the blocks and also with the strength desired. The 6-in, 7-in, and 8-in b usually have two vertical partitions and one horizontal partition, or one ve and one horizontal, for blocks 8 in wide. The 10-in and 12-in arches may either one or two horizontal partitions. Arch-blocks over 12 in deep s always have at least two horizontal partitions. In the strongest block voids are about 3 in square. "The arch-blocks must be set end to end in st courses from beam to beam, and cannot be set breaking joints, as in the CONSTRUCTION method."*

Thickness of Web. This should be at least ¾ in for porous and ½ i semiporous tiling. The thicker the webs the greater will be the strengt fire-resistance of the arch. The end-joints are always beveled, as in Fi the ends being parallel; thus all the intermediate blocks are made with the die.

Form of Skewback. An end-construction arch may have SKEWI formed of the same blocks, with notches in the ends of the blocks to fit ov

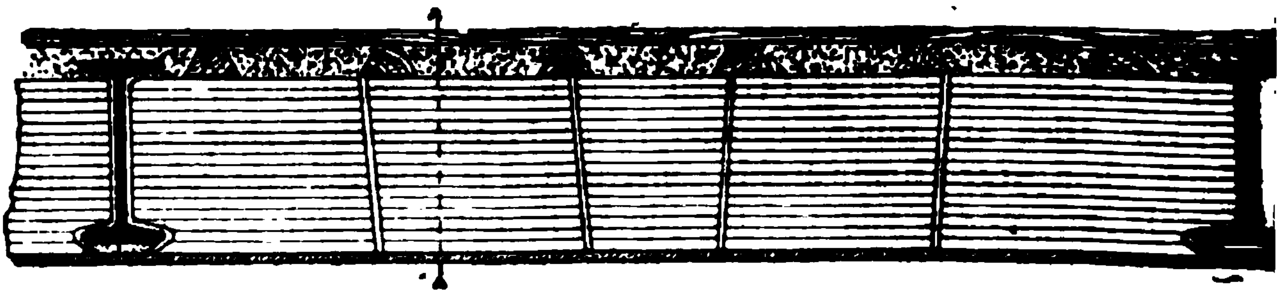

FIG. 20. Flat Tile Floor-arch. End-construction

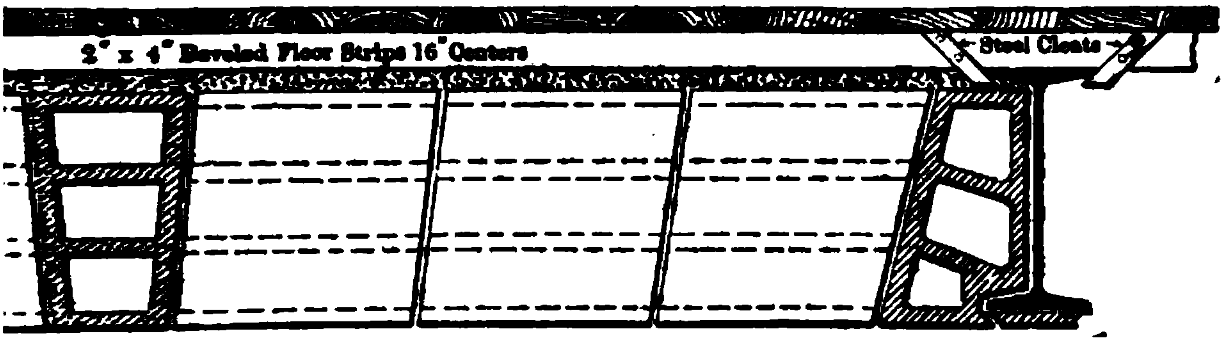
bottom flanges of the beams, as in Fig. 20. It is generally considered th end-construction skewback is much stronger than the side-construction

* Bevier.

but on account of the large amount of mortar lost in the voids and the
ulty of obtaining an even bearing with end-construction skewbacks,
also, because of the greater facility with which the side-construction skew-
s can be used, contractors generally prefer to use the latter; and this has
rise to the form of arch shown in Fig. 21. But a more important reason for
side-construction skewbacks with end-construction arches is the better
ction against fire that they afford to the beam or girder. To develop the
sary strength, side-construction skewbacks should have a large sectional
and a sufficient number of partitions, following, approximately, the lines of
t. With any form of skewback the recess for the beam-flange should be of
width, so that when the tiles are set the protecting flanges on the skew-
will not touch the bottom of the beams, but will be at least ¼ in below
. Many varieties of side-construction skewbacks are made to meet all
le conditions.

ys. Both end-construction and side-construction KEYS are used with
onstruction arches, the choice of the key depending principally upon its



21. Flat Tile Floor-arch. Combination End-construction and Side-construction

L. If the span of the arch is such that the standard intermediate blocks
e a key 6 in or more in width, the END-METHOD KEY is used, as in Fig. 20;
the space for the key is small, a SIDE-METHOD KEY, such as shown in Fig.
used. As the key is almost entirely in compression, a side-construction key
r less in width will usually give all the strength required, provided that the
ontal webs are in the same line with those in the intermediate blocks. E. V.
on, western manager of the National Fire Proofing Company, says: "We
the use of an end-construction key in all cases where possible. Our cus-
s to use side-construction keys for spaces of 6 in and under, and end-
uction keys for larger spaces. When using the latter keys we insert a
ire-clay slab between the ends of the tile."

sed Skewbacks. Where flat arches are sprung between 18-in, 20-in, or
beams it is necessary either to use a RAISED SKEWBACK or else to have a large
above the top of the tile arches which must be filled in some way. Raised
acks are preferable to a hollow space above the tiles and cheaper than
te filling. They are often used for roof-arches, because for that pur-
is seldom necessary to make the arches as deep as the beams, while the
ust be about on a level with the beams. Raised skewbacks are almost
made on the side-construction principle. Fig. 22 shows a typical form
ed skewback for end-construction arches.

t Versus Paneled Ceilings. In connection with the raising of the
above the bottom of the beams or girders, J. K. Freitag calls attention
advantages of FLAT CEILINGS, as follows: "Flat, unbroken ceilings are
to be preferred to any type of terra-cotta arch which may require a
d effect due to the projection of the girders or beams below the main

ceiling-line." A perfectly flat ceiling reflects more light, makes a better-ligh room, and deflects the heat. Paneling forms pockets for the retention of l and flame and greatly increases the exposed area.

Fig. 22. Raised Skews for End-construction Arches

Floor-Arches and Beams of the Same Depth. A deep block makes a m stronger floor than a shallower one, and for the same depth of beams a lig and cheaper floor A 12-in arch weighs less per square foot than a 10-in with 2 in of concrete filling; and it costs less.

Depth, Span, and Weight. The MAXIMUM SPANS for different depths the AVERAGE WEIGHTS per square foot of this type of arch, set in place, ar follows:

Table VII. Maximum Spans for Flat Tile Floor-Arches of Different De and Weights

Depth of arch, in	Maximum span, ft in	Weight per sq ft, lb

9	6 0	32
10	6 6	33
12	8 0	39
15	9 0	46
16	10 0	50

The weights per square foot, as given by different manufacturers vary grea due, no doubt, to the character of the material used and to the thicknes the webs.

The DEPTH OF ARCH most frequently used is 10 in, the girders being sp to use 10-in I beams for joists spaced from 5 to 6 ft apart. As a rule the d of the arch should be about equal to the depth of the beam, as it is just abou cheap and much better construction to use deeper tiles and less concrete fillin

Safe Loads for End-Construction Tile Floor-Arches. The STREN of flat arches of hollow tile depends upon the CRUSHING RESISTANCE of the m rial, the sectional area per linear foot of arch, the depth, and the span. For t reasons it is impossible to give a table for strength which applies to all arc The values given in Table VIII for END-CONSTRUCTION arches are based u arch-blocks of the cross-sectional areas, per foot, given in the second horizo

: of the table, and are intended to have a FACTOR OF SAFETY of 7, with the ght of the tile only, deducted. Mr. Hinton says: "The SAFE LOADS as they nd in the table afford a safe general statement of SAFE LOADS FOR ALL SECTIONS e they represent specifically a light section in the case of each arch."

per of the Pioneer Company, Chicago, Ill. The right to manufacture and is arch, in certain territory, has been granted to the National Fire Proofing any, and to Henry Maurer & Son, New York City. The original shape of the ile is illustrated in Fig. 24. Henry Maurer & Son have modified the shape t shown in Fig. 23, as they consider that this shape gives a stronger and y heavier arch than one of the original shape. The advantages of this re the reduction in weight for an equal strength, and the clear space of 5 ween the tiles, which avoids the cutting of the blocks for the tie-rods. rch can be adapted to any span up to 10 ft by using blocks of suitable depth.

Fig. 24. Johnson End-construction Tile Floor-arch. Original Form

The LIMIT OF SPAN, WEIGHT PER SQUARE FOOT, and SAFE LOAD of the Excel
arch (Fig. 23) is given by Maurer & Son as follows:

Table IX. Maximum Spans for Excelsior Tile Floor-Arches

Depth of arch, in	Limit of span, ft	Weight per sq ft, lb	Safe load per sq ft, lb
8	5 to 6	27	300
9	6 to 7	29	350
10	7 to 8	33	300
12	8 to 9	38	350

The National Fire Proofing Company has made arch-blocks as deep as 20
and as heavy as 56 lb per sq ft. This company and Henry Maurer & Son
semiporous material for the arch-blocks. It should be noticed that the a
made by the former has an END-CONSTRUCTION SKEWBACK, while the latter us
SIDE-CONSTRUCTION SKEWBACK. The National Fire Proofing Company f
merly used the side-construction skewback, but found that when arches of t
type were tested to destruction the skewbacks were almost invariably the p
which failed, hence their adoption of the end-construction skewback. He
Maurer & Son, however, have tested, without failure, Excelsior arches of 8 ft a
10-ft spans, and with skewbacks as shown by them, with loads of over 1 000
per sq ft. These arches have been extensively used in both eastern and west
cities

Reinforced-Tile Floor-Arches. In order to obtain a wide-span flat arch
to obtain a reduced depth of arch-block for the shorter spans, the manufactu
of terra-cotta have applied to their floor-construction the principle of rei
FORCEMENT WITH METAL, which is the basis of reinforced-concrete constructi
Compared with reinforced concrete, even when cinders are used for the ag
gate, the greater depth and hollow construction of these REINFORCED-T
ARCHES secure for them greater strength per square foot for the same wei
of construction. On the other hand, however, they are undoubtedly more
pensive than cinder-concrete floor construction, because of the material u
and the increased height of the building due to thicker floors.

The Herculean Arch.* These floor-arches are built of semiporous ter
cotta blocks, 12 by 12 in on top and varying from 6 to 12 in in depth, accord

* Patented and manufactured by Henry Maurer & Son, 1898 and 1900.

: span and load. In the sides of the blocks are grooves to receive 1¼ by ⅜-in T bars. The blocks are laid end to end the entire length of the with a bearing of from 4 to 6 in on the walls or girders, presenting two uous grooves, which are filled with cement mortar, and into which the s are then inserted. The T bars must, of course, extend the full length of an. The grooves in the next course are then filled with cement mortar e blocks pushed into place, thus thoroughly covering the steel with mortar. ints between the blocks are filled with cement mortar and the blocks are o break joint endwise, as in Fig. 25. This floor has been used for spans

Fig. 25. Herculean Reinforced, Tile Floor-arch

g from 19 to 23 ft. The WEIGHT per square foot given for the terra-blocks and steel T bars is 26 lb for blocks 6 in deep, 33 lb for 8-in blocks, r 10-in blocks and 51 lb for 12-in blocks. The manufacturers estimate E LOADS for this construction as follows:

For a 12-in arch with a 20-ft span, 400 lb per sq ft.
For a 10-in arch with a 16-ft span, 400 lb per sq ft.
For a 8-in arch with a 12-ft span, 150 lb per sq ft.

CHIEF ADVANTAGE of this construction is said to be its low cost as com-with the cost of systems equally fire-proof and requiring steel beams or 8 ft. It is particularly well adapted to buildings with masonry walls titions, as in such buildings little or no structural steel is required. The nstruction affords, also, an unusually smooth undersurface, thereby g the cost of plastering. No TIE-RODS are required for this floor.

Johnson Long-Span Flat Floor-Construction. This REINFORCED-OOR was invented by E. V. Johnson, and is now controlled and erected National Fire Proofing Company. Its general construction is as follows: orary flat centering is first erected, and over this is spread a layer of rtland-cement mortar about ¾ in thick. On top of this mortar is laid N FABRIC containing steel rods varying from ¼ to ½ in in diameter, ng to the span, and spaced from 2 to 8 in, center to center. Another the same mortar is then spread on top and hollow tiles, from 3 to 12 in in according to the span, are then set in the mortar and laid so as to BREAK

joint and to form continuous rows from one support to the other. A lay of concrete, also, about 2 in thick, is usually spread on top of the tiles. Fig. 2

Fig. 26. Johnson Reinforced, Tile Floor-arch

shows the general method of construction of this system, but without the rod which are inserted in place as the fabric is used. For short spans the fabr can be used without the rods. This system differs from the flat concrete syste only in the substitution of hollow tiles for the concrete in the upper portion the slabs, the strength of the floor depending upon the REINFORCEMENT ar the ADHESION of the cement mortar to the steel and tiles. As the tiles a covered both on the bottom and top with concrete, the FIREPROOFING PRO ERTY, also, is measured by the resistance of the concrete and not by that of th tiles. Tests have shown that the ADHESION of the mortar is perfect and that will stand a high temperature without injury. This construction can be us for any span up to 25 ft, the most ADVANTAGEOUS SPAN being about 16 ft. Th WEIGHT per square foot, including the fabric and the cement on the bottom ar in the joints, but not on top of the tile, is as follows:

Depth of tile, inches............	12	10	9	8	7	6	5	4
Weight per square foot, in pounds	60	55	45	42	37	34	26	24

The concrete above the tile should be figured at 12 lb per sq ft for each in in thickness. The STRENGTH of the floor, with 1 in of 1 : 3 Portland-ceme mortar on top of the tiles, is given in Table X.

The New York Reinforced-Tile Floor-Arch. This arch (Fig. 27) w designed by P. H. Bevier, of the New York City branch of the National Fi Proofing Company, for use "when a light and cheap but strong floor constru tion with a flat ceiling is required, and is particularly adapted to wide spa in shallow beams. When light floor-construction with deep beams is necessa it can be secured by setting the blocks level with the tops of the beams and usi a flat metal lath ceiling, or by omitting the ceiling a panel effect is obtaine When shallow beams are used the blocks are set level and 1 in below the botto of the beams. Light cinder concrete or dry cinders are used to level up to th top of the beams. A WIRE-TRUSS REINFORCEMENT, similar to that shown in Fi 28, used in this system, is shipped to the building in reels, and is cut to prop

The floor has successfully passed the fire and load tests of the
uildings, of New York, and as a result has been used in a number of
gs in New York. Load tests were made to determine the ULTIMATE
the 6-in arch on a 6-ft span, and it was found to be 1 600 lb per sq ft."

stavino Tile-Arch System. This is a method, devised by R.
of New York and Boston, of constructing floors, partitions, stair-

cases, etc., by means of THIN TILES, 1 in thick, about 6 in wide, and from 12 t 24 in long, all bonded together in Portland-cement mortar so as to make o solid mass. The floors are built by spanning the spaces between the girde with single arches, vaults, or domes, constructed of two, three, or more thic nesses of 1-in tiles, the number of thicknesses depending upon the dimensio of the arches or vaults. In its best application, steel is used in tension only i tie-members; and in place of steel girders, tile girders are constructed of th same material. Wherever steel is used it is embedded in the masonry constru tion. One of the earliest notable buildings in which this system was used is th Boston Public Library Building, completed in 1895. Some of the later importa constructions are the Cathedral of St. John the Divine, New York City; th Minnesota State Capitol Building, St. Paul, Minn.; the Girard Trust Company Building, Philadelphia; the Chicago and Northwestern Railway termin station, Chicago; the Pennsylvania and the New York Central Railroad te minal stations, New York City; and the Hall of Fame, University of New Yor New York City.

An illustration of the wide spans that can be safely used with this system construction is seen in the Cathedral of St. John the Divine in New York City The floor above the crypt, measuring 56 by 60 ft, with no interior support and designed to carry a safe load of 400 lb per sq ft, was constructed on th principle. Wherever a VAULTED CEILING is desired this form of constructio seems to be well adapted for use. Floors built in this way have been teste under the supervision of the New York City Building Department up to 3 700 l per sq ft, on spans of 10 ft. When used between I beams the only steel bean required are those spanning from column to column. Architects contemplatin the use of this system of construction are advised to consult the R. Guastavin Company before letting any contracts. Wherever vaulted ceilings are require this construction should be at least as cheap as any other form of equally fir proof construction, and it is often cheaper. One particular advantage of th system is that frequently the soffit-course of tile is of PRESSED OR GLAZED MATE RIAL, making a most effective and permanent finish, as in the case of the Cit Hall station of the New York City subway. This station was constructed f very heavy loads and without the use of steel.

Incidentally, attention may be called to the RUMFORD TILE developed in co nection with this construction, to be used as the first course of tile, that is, o exposed surfaces on the interior of auditoriums, on account of its sound-absorbin character. Professor Sabine of Harvard University concluded from his in vestigations that this tile "has over sixfold the absorbing power of any existin masonry construction, and one third the absorbing power of the best-know felt."*

Concrete Floors. Concrete used in fire-proof floors may be either PLAIN o REINFORCED. Without reinforcement its use is generally practicable for ver short spans only, on account of its weight. In this chapter it is considered onl as a FLOOR-FILLING between steel beams. Chapter XXIV is devoted to a di cussion of the principles governing the design and use of reinforced concrete.

Advantages of Reinforced Concrete for Floor-Construction. Althoug many ADVANTAGES are claimed for reinforced concrete over the tile system the principal advantage is that of economy, taking into account the cost o both the steel framework and the filling between. The other important ad vantages are less weight per square foot of floor (usually but not always th case), adaptability to irregular framing, and rapidity of construction. Excep in the immediate locality of the tile-factories, fire-proof floors of concrete c

* The Brickbuilder, January, 1914.

ally be placed at less expense than is incurred in setting floors of hollow tile; when the spans permit the use of cinder concrete, the concrete floors are ter than those of the tile, when both floors have the same strength. Some he long-span tile-systems, on the other hand, are much lighter than many e concrete floors that are now being built. The materials entering into the struction of reinforced-concrete floors are readily obtained in almost any lity, no specially prepared material is required, except perhaps in a few ial forms of reinforcement, and the work can be done almost entirely by illed labor. Less capital is required for concrete work than for the tile-structions, and no material need be carried in stock during an idle period, pt tools, mixing-machines, old centering, etc. That the above advantages real is sufficiently proved by the immense amount of reinforced concrete under construction throughout the world. Wherever a floor is to have a hed, cement surface, reinforced-concrete constructions are considerably per than any tile system, because in the former, the entire concrete is used ive strength, while with the flat-tile arches it merely increases the dead weight.

isadvantages of Reinforced Concrete for Floor-Construction. One ded DISADVANTAGE connected with concrete floor-construction is the inter-ce in a large measure with the progress of other parts of the work. During nstallation, there is a constant dripping from the floor, making it some-s impossible to continue other lines of work. After the completion of the s a long time is required, depending upon the weather, for the drying out, e interior finishing can proceed.

omposition of the Concrete. The materials used for concrete are dis-ed on pages 240 to 241 and on page 817. Portland cement, only, should ed in any floor-construction. For most reinforced-concrete floors, having an between the steel beams of 8 ft or less, CINDER CONCRETE is generally for the reason that concrete mixed with cinders is much lighter than that d with broken stone or gravel. The usual PROPORTIONS OF CINDER CON-E are one of cement, to two of sand, and five or six of cinders. For a first-concrete the cinders must be screened through a mesh not larger than n, and only hard-coal cinders should be used. Good cinders may some-s be obtained from power-plants using soft coal, but they must be well ened and free from ash. Concrete mixed with common ashes, a mixture oc-nally used, has little strength and is totally unreliable. For all spans ex-ing 8 ft, either GRAVEL OR BROKEN ROCK should be used, and these should ixed with one part cement, to two of clean sharp sand, and four of stone avel. The WEIGHT OF CINDER CONCRETE will vary from 80 to 110 lb per t, depending upon the coarseness of the material, the quantity of sand, and amount of tamping. For ordinary purposes a 1 : 2 : 5 cinder concrete ld be used, weighing 96 lb per cu ft, or 8 lb per sq ft per inch of thickness.

rms of Reinforcement. While steel in small sections is used almost ely for the reinforcement, there is a great variety in the shape and char-r of the metal employed. Different FORMS OF REINFORCEMENT are described discussed in Chapter XXIV. All of them may be used, and most of them ow being used in floor-construction. In addition to those forms discussed , others that are not readily adapted to beam-construction are used in -construction. Such are the METAL FABRICS described farther on under ifferent types of construction. The proper position for the reinforcement floor-construction is that in which it will take the TENSIONAL STRESSES, in floor-slabs, near the lower surface. The most logical form is that of OR BAR. A greater number of small rods or bars is preferable to a smaller ber of larger ones, because the proportion of the AREA OF ADHESION between

steel and concrete to the SECTIONAL AREA OF STEEL is greater in the former
This result is apparently attained in systems in which wire fabrics are
But the disadvantage in the use of the smaller reinforcement is the greater
sibility of CORROSION and consequent failure of the construction. There
further disadvantage in the use of wire fabrics; they are easily displac
the process of placing of concrete, either getting too low and becoming ex
to fire or corrosion, or getting too high with a corresponding weakening o
floor. Another detail that must be remembered when using metal fab
that the mesh must be large enough to allow a good BOND to be formed bet
the concrete above and below it. Reinforcements in the form of bars set
tically in the concrete have a tendency to SHEAR through slabs which are
heavy loads. The best and most LOGICAL REINFORCEMENT for fire-proof
consists of from ½ to ¾-in round or square rods, either plain or defor
spaced at varying distances to suit the spans and loads.

Necessity for Cross-Bars. Where wire strands or bars are used for forcement it is essential to have CROSS-BARS as well as TRANSVERSE TEN BARS, because, when the loads are heavy and concentrated, or when a h body falls upon a slab the concrete will crack between the carrying bars. can be readily demonstrated by testing with a drop-test a floor-slab that h cross-bars. When the load is UNIFORMLY DISTRIBUTED the cross-bars ar brought into play; floor-loads, however, are more often CONCENTRATED UNIFORMLY DISTRIBUTED

Segmental Concrete Floor-Arches. For heavy warehouse-floors ARCH SYSTEMS are preferable to the FLAT SYSTEMS, because in the forme concrete is used in its strongest form, and less reinforcement is required. warehouses, also, a ceiling formed of a series of arches is not objection For spans between floor-beams of 5 ft or less, a 1 : 6 gravel-concrete arch, thick at crown and without any reinforcement, should sustain, without c ing, a distributed load of 1 500 lb per sq ft. For spans exceeding 5 ft, the brated Austrian experiments (1891–1892) seem to show that the reinforci concrete with small I beams adds greatly to the strength of the arch; but small rods or netting are not of sufficient advantage to warrant the addit expense.* Tests made on arches of 8-ft span gave the following results:

A concrete arch, 3⅛ in thick, 9½ in rise, broke at 1 130 lb per sq ft. A M arch (wire netting), 1 15/16 in thick, 10¼ in rise, or about one half the thic of the concrete arch, failed at 1 217 lb per sq ft. A brick arch, 5½ in t 9.85 in rise, failed at 885 lb per sq ft. A hollow-brick arch, 3 15/16 in thick, in rise, failed at 401 lb per sq ft. A concrete arch, 13-ft span, 3 15/16 in thick, in rise, failed at 812 lb per sq ft. A Melan arch, 3⅛ in thick, 11.4 in rise, b at 3 360 lb per sq ft. The Melan arch had I beams 3⅛ in deep, spaced apart. The structure was one year old when tested.

The concrete arch, considered as a monolithic construction, if built of concrete, is superior to the brick arch. The cinder-concrete arch is in only in point of strength. Such an arch should be at least 4 in deep a crown, and the rise should be not less than one eighth the span. Cinder crete should not be used for spans exceeding 8 ft. The strength of such a for ordinary cinder concrete is about the same as that of a 6-in segmenta arch of the same span, as given in Table V. All arch systems, whether of co or tile, require tie-rods between the beams to take up the thrust of the a (See page 865.)

Weight of Segmental Concrete Arches. The weight of solid segm

* See Architecture and Building, Jan. 4, 1896.

...s may be found by the following formula which gives results approximately ...t when the rise of the arch is not more than one sixth of the span:

$$W = (w/12)(c + 4S/p)$$

...ich

W = weight of arch, in pounds per square foot;
w = weight of material, in pounds per cubic foot;
c = thickness of arch at crown, in inches;
S = span of arch, in feet;
p = ratio of span to rise of arch.

...ble XI gives the weight per square foot of arches having a thickness of 4 in ...crown and constructed of stone or gravel concrete, taken at 144 pounds per ...foot, for various spans and ratios of span to rise. For greater thicknesses ...crown these weights should be increased by 12 lb for each inch of additional ...ness. For other materials the weights are directly proportional to the ...ts of the materials. Thus, if cinder concrete weighing 102 lb per cu ft is ... the weight of the arch for any particular span and ratio of span to rise ...2/144, or 17/24, of the weight given in the table for the same span, ratio, ...hickness at the crown. Cinder concrete of good quality weighs, according ...nsity, from 96 to 108 lb per cu ft.

Table XI. Weight per Square Foot of Segmental Concrete Arches

Concrete taken at 144 lb per cu ft

...tio of ...an to rise	Thickness of arch at crown, in	Span in feet					
		5	6	7	8	9	10
6	4	88	96	104	112	120	128
6½	4	85	93	100	107	114	122
7	4	82	89	96	102	109	116
7½	4	80	86	93	99	106	112
8	4	78	84	90	96	102	108

...t Reinforced Floors. These floors consist of slabs of concrete, varying ...hickness according to the span and load, constructed between the steel ...-beams and reinforced near the lower surface with steel in one of the shapes ...red to on page 843, and further described under their respective names. For ...nary loads the thickness of the slab should be at least ⅝ in for each foot of ..., with a minimum thickness of 3½ in. Thinner slabs have been used, but ...thickness should be carefully considered for each particular case. The floor-...s are not usually of the same depth as the beams supporting them. The ...tion of the slabs, therefore, determines the character of the ceiling. When ...bottom of the slabs is placed at or below the lower flanges, a flat ceiling results, ...the space over the slabs must be filled to the underside of the flooring with ...incombustible material, thus often increasing the weight. When the slabs ...t at the top flanges, there is a paneled ceiling, unless a hung ceiling is pro-...d.

...rength of Flat Floor-Construction. The following empirical formula, ...esenting the practise established by the New York Building Code, is based on ...nvestigation of cinder concrete floor-construction made by Harold Perrine

and George E. Streban,* under the joint auspices of Columbia University the Bureau of Buildings, Manhattan, New York.

$$w = Kda/S^2$$

in which

w = safe load, in pounds per square foot, including the weight of slab;
d = distance, in inches, from top of slab to center of reinforcement;
a = cross-sectional area, in square inches, of the reinforcement, for foot of width of slab;
S = span, in feet, of slab;
K = a coefficient with values as follows: when cinder concrete is 26 000 if the reinforcement consists of steel fabric continuous supports; 18 000 if the reinforcement consists of steel rods or shapes securely hooked over or attached to the supports; and 1 if the reinforcement is not continuous over the supports; and stone or gravel concrete is used, 30 000, 20 000, and 16 000, res ively, for the corresponding conditions.

The material contemplated by this formula is a concrete consisting of one of Portland cement, and not more than two parts of sand, and five parts of s gravel, or cinders. The reinforcement consists either of steel rods or suitable shapes, or steel fabric. In case cold-drawn steel fabric is used, th sional reinforcement should not be less than 1⅓00%, and in case other for reinforcement are used, not less than 2⅓00%, the percentage being based o sectional area of the slab above the center of the reinforcement. For p protection against fire and corrosion the center of the reinforcement should least 1 in above the bottom of the slab, but there should always be at least of concrete outside of any part of the reinforcement. The formula should n applied to spans exceeding 8 ft. Cinder-concrete floors should be limit that span in any case.

Expanded Metal. This material is now so well known that it requires a brief description. The diamond mesh shown in Fig. 29 is used in floor

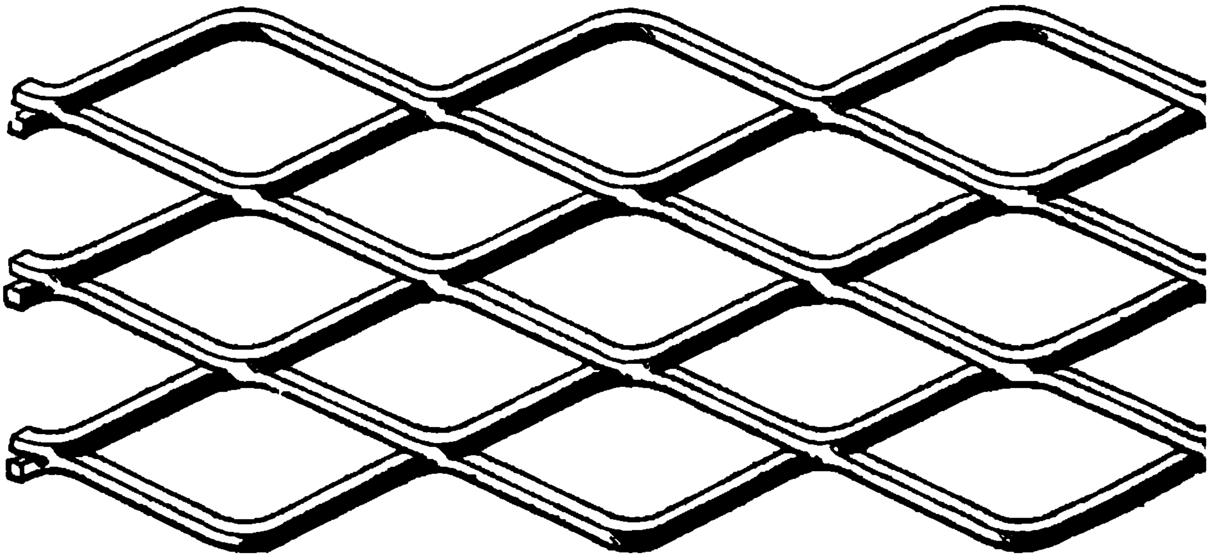

FIG. 29. Expanded Metal, Diamond Mesh

struction. For this purpose the 3-in mesh is used, the size of the mesh designated by the width of the diamond-shaped spaces. It comes in 8, 10, 12, and 16 ft long, and from 3 to 8 ft wide, according to the width mesh. It is made from a soft, tough steel of fine texture, varying in thic from No. 13 to No. 1, Stubbs gauge. The standard sizes offered by the

* Trans. Am. Soc. C. E., Vol. LXXIX. 1915, page 523.

ited Expanded Metal Companies and the Northwestern Expanded Metal mpany are in accordance with a decimal variation in cross-section, thus: 5, 0.30, 0.35, 0.40, etc., sq in per ft of width. The designations of the sizes cate the cross-sectional areas per foot of width, thus: 3–9–20 denotes a 3-in sh, No. 9-gauge plate, and a cross-sectional area of 0.20 sq in per ft of width. Sharon Steel Hoop Company and also the General Fire Proofing Company r from eight to ten sizes of expanded metal with a range sufficient to take t of the needs of concrete-floor designs.

Concrete and Expanded-Metal Floor-Construction. Of the numerous es of floor-construction possible with expanded-metal reinforcement, the shown in Fig. 30 is generally used and recommended. At the right hand

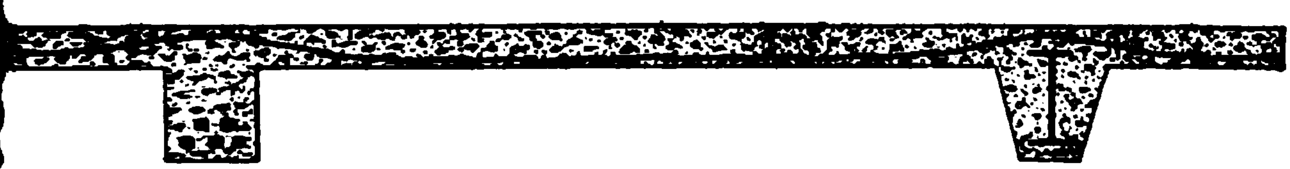

FIG. 30. Concrete Floor-construction. Expanded-metal Reinforcement

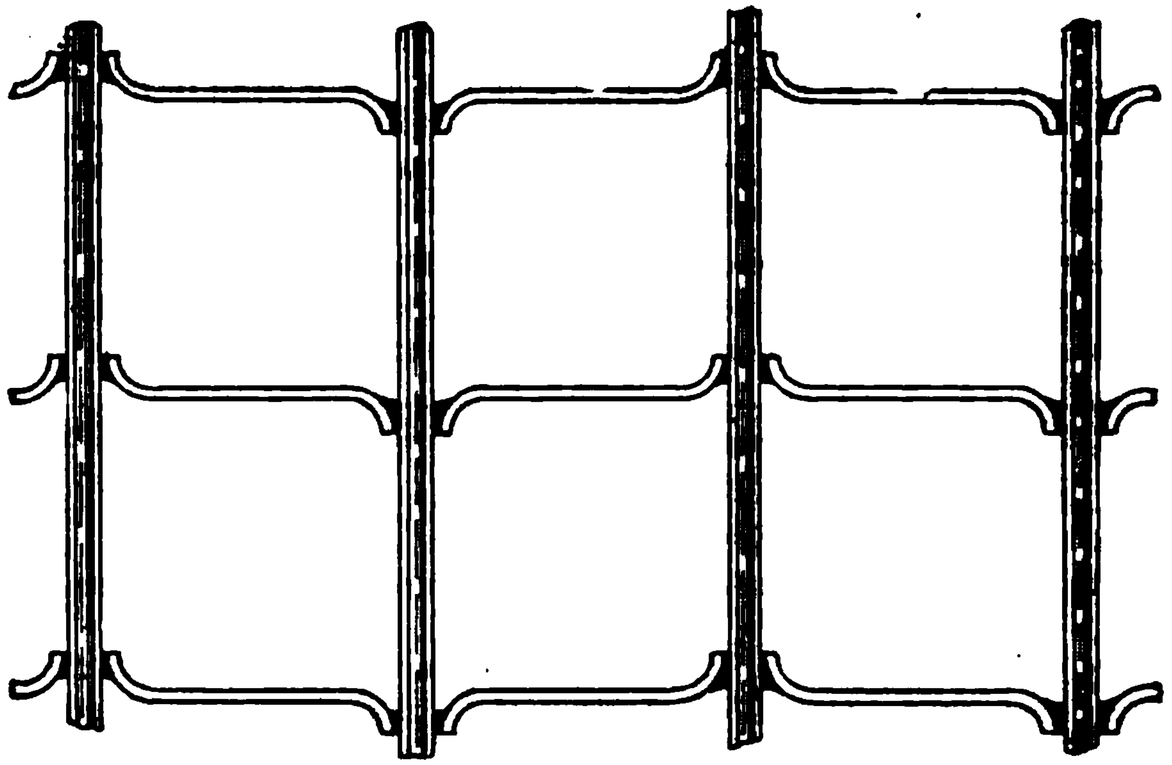
the figure is shown the construction when there are steel beams, and at the hand when there are reinforced-concrete beams. The advantages claimed expanded metal as a reinforcement are: a better arrangement in the con- e than is possible with an equal amount of material in any other form; great iency in the carrying of concentrated loads, due to the obliquity of the nds; a uniform distribution of small sections at frequent intervals, pref- ble to larger sections at greater intervals; an increased ultimate strength high elastic limit, due to the method of manufacture, thus combining advantages of a low-carbon steel with a high ultimate strength; and a hanical bond with the surrounding concrete. When used between I beams, hout other reinforcement, the spans usually vary from 6 to 8 ft, although ls 12 ft wide between beams have been constructed. In placing expanded al in the concrete, it is necessary to lap the sheets on the ends up to and uding 3–9–20, one diamond (8 in); from 3–9–25 to 3–6–60, one and a half monds (12 in); and heavier than 3–6–60, two diamonds (16 in).

Table XII. Properties of Rib-Metal

Size-number	Width of sheet, in	Area of metal per foot of width, sq in
2	16	0.540
3	24	0.360
4	32	0.270
5	40	0.216
6	48	0.180
7	56	0.154
8	64	0.135

ib-Metal. The Truscon Steel Company's factory, at Youngstown, O., is ufacturing a steel reinforcement for concrete floors consisting of a series traight ribs or main tension-members rigidly connected by light cross-ties nded from the same sheet of metal in the form of a mesh (Fig. 31). It anufactured from medium open-hearth steel in seven sizes of mesh, 2, 3, 4,

5, 6, 7, and 8 in, and in lengths up to 18 ft. It is supplied in either flat or cur sheets, and longer lengths and special sizes of mesh can be provided. The wi



Area of rib 0.09 sq in

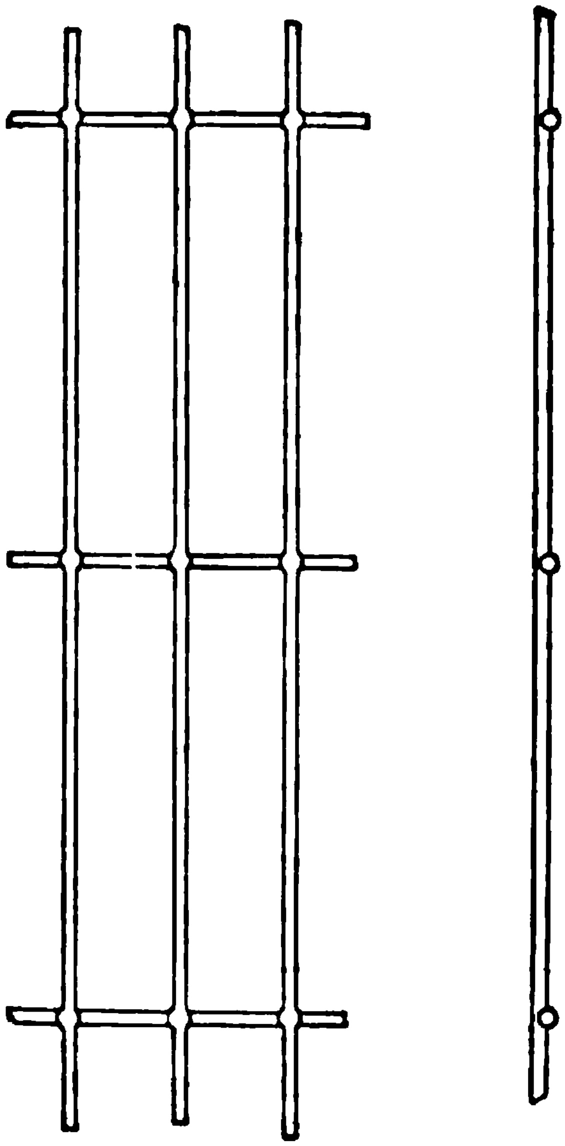

Fig. 32. Welded-metal Fabric. Clinton Wire Cloth

of sheet is governed by the size of m there being nine bars or ribs in each sh

Welded-Metal Fabric. The Wick Spencer Steel Corp. manufactures a wel fabric or mesh which has been extensiv used in the United States as a reinfo ment for concrete construction of all ki Fig. 32 shows the general style of the fal the meshes and wires of which can be va indefinitely, upwards from a 1-in m The advantage claimed for this fabric reinforcement for slab-construction is the carrying wires may be varied, bot size and spacing, to give the necessary for any given weight and span, and distributing or cross-wires, also, may varied in the same way. The directio the wires coincides with the LINE OF ST so that there is no tendency to distort rectangle of the mesh. The cross-w being welded to the carrying wires, rigidly held in place and prevent the fr from slipping in the concrete. The c is made that the elongation that takes in the carrying wire under the stress of h loading, is divided along the carrying as often as the cross-wires occur, instea being concentrated at one point as i case with loose rods or wires. In the m

monly used the carrying wires vary from No. 10 to No. 3 in size (Washburn Moen gauge), and are spaced from 1 to 4 in on centers; while the distributing wires vary from No. 11 to No. 6 in size, and are spaced from 3 to 12 in on ters. Welded metal is manufactured in long rolls, and by its use all joints laps are avoided. A floor can be made with a continuous metallic bond from to wall, that is, when the mesh is laid over the tops of the steel beams. The th of the rolls varies from 48 to 86 in.

Lock-woven Steel Fabric. This fabric* is made up in a rectangular mesh, usual spacing of the longitudinal wires being 3 in on centers and that of the nsverse wires 12 in on centers. These spacings can be easily varied to meet

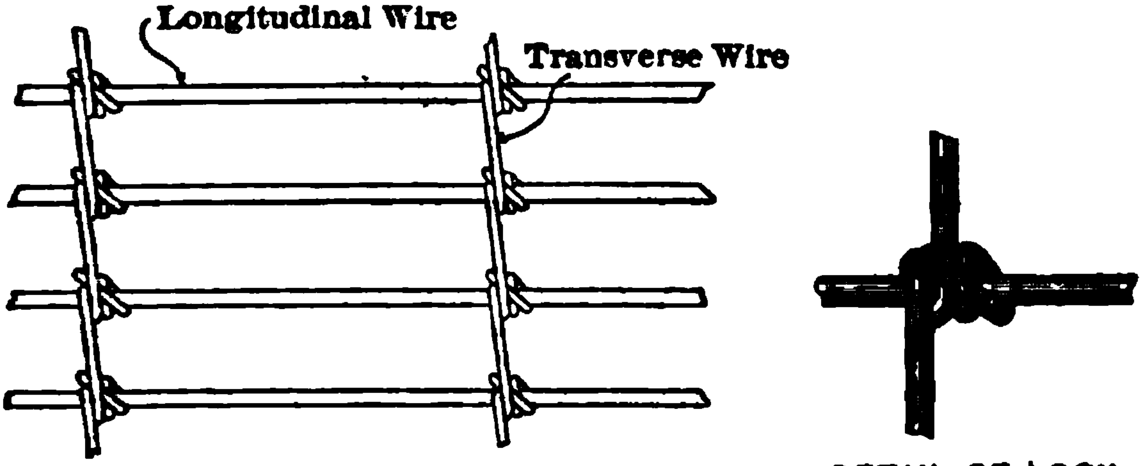

FIG. 33. Lock-woven Fabric

cial conditions. The fabric is usually made 54 in wide and comes in rolls taining from 150 to 600 lin ft, the 150-ft length being commonly used. While usual width of the fabric is 54 in, it can be varied in multiples of 1½ in from n up to a maximum of 54 in. The longitudinals or carrying wires of the ric are held in place by the transverse wires as shown in Fig. 33. The longi-

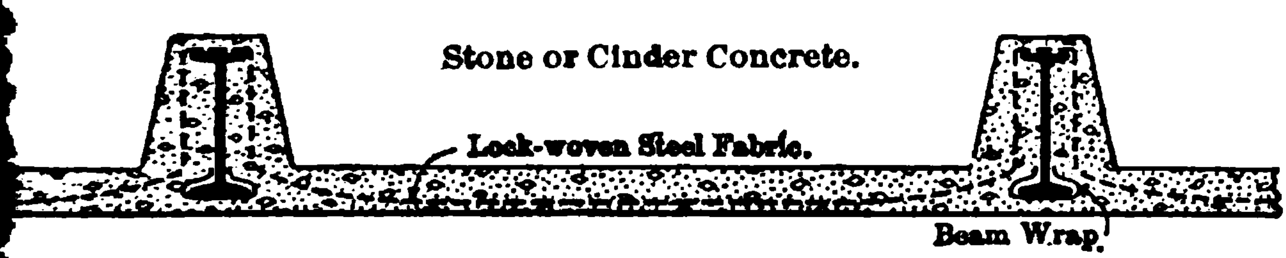

FIG. 34. Concrete Ceiling-slab Reinforced with Lock-woven Fabric

nal wires can be furnished in sizes varying from No. 14 to No. 7 gauge, the ional area of the fabric ranging from 0.0201 sq in to 0.1968 sq in per ft of th. Heavier fabric can be furnished to meet special conditions. The transe wires are usually No. 14 or No. 12. The longitudinal wires are made by a ial process which gives them an ULTIMATE TENSILE STRENGTH of from 150 000 80 000 lb per sq in, with a correspondingly high ELASTIC LIMIT. The fabric be furnished either black or galvanized. This fabric has the general advans common to any continuous, rectangular-mesh material, as it provides a TINUOUS BOND from end to end of a structure, and the wires are so placed that y lie parallel to the LINES OF STRESSES which they are called upon to carry. The dard type of construction for floor-slabs and roof-slabs is similar to that n in Fig. 30 for expanded metal. Where a flat ceiling is desired the type onstruction shown in Fig. 34 is very useful. Both of these types have been ed by the Bureau of Buildings of the City of New York on spans up to and

* Controlled by W. N. Wight & Company, New York City.

including 6 ft, for live loads running from 130 to 330 lb per sq ft; and on spa
7 ft, approvals have been given up to 175 lb per sq ft, and on spans of 8 ft, u
150 lb per sq ft. The arches were constructed of cinder concrete and the fig
given are based on a factor of safety of 10. In addition to its use for the
struction of floor-slabs and roof-slabs, the fabric is suitable for use in panel-w
sewers, penstocks, and tanks, and in all other places where a sheet-reinforcem
can be used to advantage.

Triangle-Mesh Wire-Fabric Reinforcement. Under this name the Am
can Steel and Wire Company is manufacturing a wire fabric of cold-drawn
wire for the reinforcement of fire-proof floors. A detail of the standard mat
is shown in Fig. 35. The triangular mesh is built up of either single or stra
longitudinals with the cross-wires or bond-wires running diagonally across
width of the fabric. It is claimed that the triangular mesh affords an
distribution of the steel, reinforcing in every possible direction, and that

FIG. 35. Wire-fabric Reinforcement, Triangular Mesh

strength is increased by reason of the truss-construction. For floor-reinf
ment, this fabric is used the same way that any of the other fabrics previo
described are used, and as indicated in Figs. 26, 30, and 34. The longitu
wires in Triangle Mesh are invariably spaced 4 in on centers, but the diag
wires may be spaced either 4 or 8 in apart. The manufacturers can fu
different styles, giving variations in the cross-sectional area from about 0.0
in to about 0.395 sq in per ft in width of the fabric, or a variation in weigh
square foot of from 0.2 to 1.6 lb. The material is furnished either galva
or plain. The longitudinal wires are made of either a single wire or of tw
three wires stranded. The cross-wires or bond-wires are of either No. 1
No. 12¼ gauge. Special sizes of additional area can be furnished upon app
tion to the company. This fabric is said to have an ultimate strength of no
than 85 000 lb per sq in.

Dovetailed Corrugated Sheets. Ferroinclave. Sheets of thin steel c
gated so as to form dovetailed grooves have been used as a reinforcement and
tering for concrete-steel, the dovetailing serving to unite the sheets to the
crete. The Brown Hoisting Machinery Company of Cleveland, Ohio,

tented, under the name Ferroinclave, a tapered corrugation which is small ugh to hold hard mortar, and hence can be plastered on the under side. Fig. shows a partial section of the Ferroinclave corrugated sheets, the depth of the rugations being ½ in, the distance from center to center of corrugations 2 in, d the corrugations, with the opening between the edges, ⅞ in. The tapering of e corrugations is of especial advantage for roofs, as it allows the sheets to be pped at the end-joints, making a roof absolutely tight, even if water should etrate the cement coating. The principal advantage in the use of corru- ted sheets for floor-construction is that they sustain the concrete, when the ns are of moderate width, before it has set, thus saving the cost of centering d the time required to put it in place. This advantage, however, appears to offset by the high cost of the sheets when they have to be shipped. For roofs, wever, this construction is light and relatively cheap, as the total thickness ed not exceed 1¼ in for spans of 4 ft 10 in. To make the roof water-tight me water-proof covering is required. With a good coat of hard plaster or uged mortar on the under-side, the iron will not be affected by heat in case of e until a considerable time has elapsed; and even if the mortar on the under- ide should be more or less dislodged by the streams of water, it can be replaced,

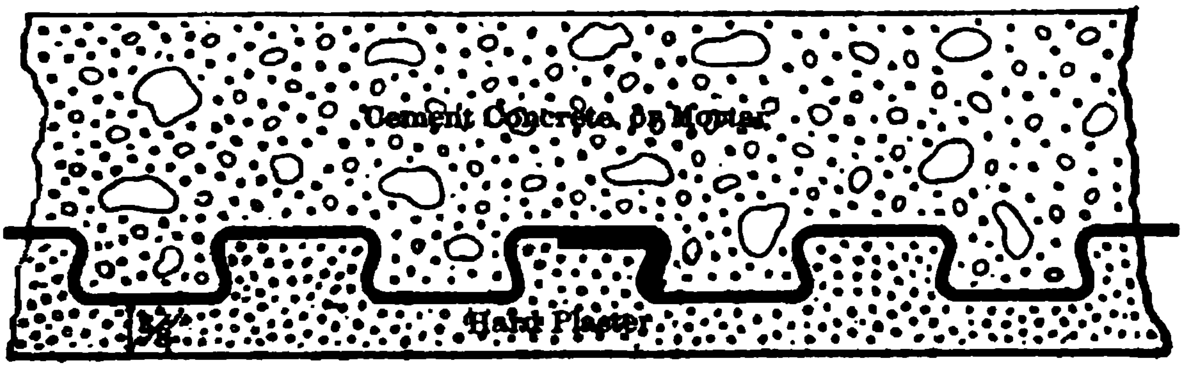

Fig. 36. Ferroinclave Reinforcement for Concrete Floors

t a very slight expense. Another advantage in the use of Ferroinclave for roofs that a building can be covered and made water-tight in the most severe winter eather and the cement applied during the following spring.

Ferroinclave is made in sheets 20 in wide and up to 10 ft long, and it is usu- lly of No. 24 gauge. For roofs it is attached to purlins in the same way that on roofing is attached, the most economical spacing of the purlins being 4 ft 10½ center to center, which accommodates sheets 10 ft long and leaves an end- p of 3 in. For the cement top coat on roofs, a mixture of one part Portland ment to two parts sand, applied to a thickness of ⅜ in above the top of the eets, is sufficient. For floors a rich gravel or crushed-stone concrete should be ed, the thickness being governed by the span and the loads to be supported.

The following table shows the ultimate strength of No. 24 Ferroinclave with fferent thicknesses of concrete, as determined by actual tests with sheets 20 in ide over a 4-ft 10½-in span:

hickness in inches of 1 : 2 mortar above the metal	1½	2	2½	3	3½	4
ltimate strength in lb per sq ft for a span 4 ft 10½ in	615	915	1220	1560	1860	2120

A factor of safety of 6 should be ample for ordinary loads.

Ferroinclave is especially adapted for the roofs and floors of large manufac- ring plants, and may be used to advantage for partitions, stair-treads, vats, ater-closet partitions, and fire-proof doors.

Berger's Multiplex Steel Plate. Fig. 37 shows a section of a corrug steel plate manufactured by the Berger Manufacturing Company, Can Ohio, for floor and roof-construction, the plate being an invention of G. Fugn As shown in the illustration, it consists of a series of vertical corrugation sheet steel, painted or galvanized, ending at the top and bottom in three l circle arches, separating the vertical sides of the corrugations from each o and giving stiffness to the top and bottom of the plate. The plate is made depths, *D*, of 2, 2½, 3, 3½, and 4 in, and in corresponding widths of 13½, 14½, and 15 in. The maximum length of plate is 10 ft. It can be made of gauge of steel, from No. 24 to No. 16, but No. 18 is as heavy a weight a generally required. For floors and roofs, the corrugated plate is laid on to the beams and the top portion filled with concrete and leveled off about above the plate. For wooden floors the nailing-strips may be embedd the concrete and the bottom of the strips raised only about ½ in abov top of the plate. The construction is very light and strong and require centering. It cannot be plastered, however, on the under side; and whe

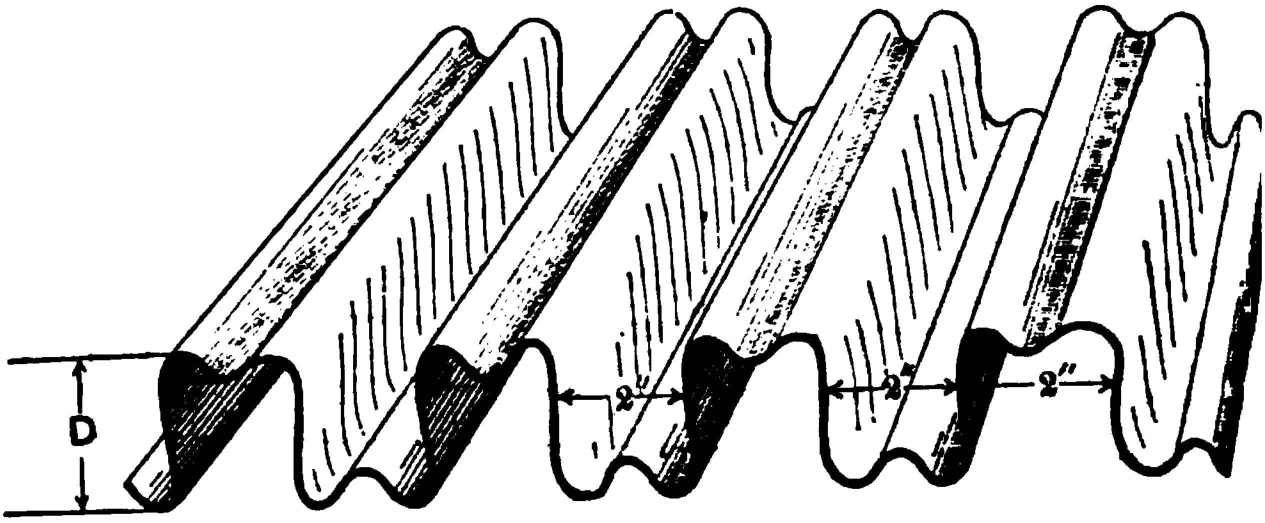

FIG. 37. Berger's Multiplex Steel Plate

plaster ceiling is required it must be constructed independently of the plat means of furring-strips and metal lath. The weight of the 4-in plate, wit 1 : 2 : 5 furnace-slag concrete leveled 1 in above the top of the plate, is ab 40 lb per sq ft, and the safe load for a 10-ft span is given at 270 lb per sq While this floor has several practical advantages, it cannot be consid thoroughly fire-proof, because the metal is exposed on the bottom. But a plastered ceiling on the under side, the iron would probably not be affe by any ordinary fire before the latter could be controlled.

Permanent Centering. Numerous forms of sheet-metal fabrics have b developed in recent years for use as floor-reinforcements. They consist, erally, of steel plates pressed into series of solid ribs, variously spaced, betw which the metal is stamped or perforated, or deployed into an open mesh-w The characteristic form is shown in Fig. 38. The mesh is kept small eno to prevent ordinary concrete from passing through. For use as a reinforcem the sheets are furnished either in flat or segmental form. A 1 : 2½ : 5 ston cinder concrete may be used, the thickness depending upon the span and the l to be provided for. For spans exceeding from 3 to 5 ft, according to the gaug metal, the sheets must be temporarily supported until the concrete has set. difficulty of providing efficient fire-protection on the underside of reinfo ments of this type, and around the lower flanges of the supporting steel be is a serious disadvantage. Besides, the bond between the metal and the f concrete is on one side of the sheet only. Some of the forms now on the mar

with their special characteristics, are briefly described in the following paragraphs.

Rib-Truss. These plates, manufactured by the Berger Manufacturing Company, Canton, Ohio, are designed with five longitudinal ribs, 6 in on centers, and ½, ¾, 1, and 1½ in high. The metal between the ribs is slit into trusses which are further reinforced with beads at right-angles to the main ribs. The standard sheets are 24 in in width and are carried in stock in lengths up to ft, and made of No. 24, 26, 27, and 28-gauge metal.

Self-Sentering. In this form, manufactured by the General Fireproofing Company, Youngstown, Ohio, the ribs are 1¾ in in height, 3⅝ in on centers, and connected by expanded metal. The sheets are 29 in in width and come in lengths from 4 to 12 ft, varying by units of 1 ft. Self-Sentering is made of Nos. 26, and 28-gauge metal. (See, also, page 885.)

Hy-Rib. Hy-rib metal, now controlled by the Truscon Steel Company, Youngstown, O., is made in sheets measuring 10½ in from center to center of side ribs and having four ribs 1³⁄₁₆ in in height; and also in sheets 14 in in width having three ribs. There is also a type known as the Deep Rib. The lengths are 6, 8, 10, and 12 ft. The sheets are of No. 24, 26, or 28 United States gauge, and are furnished either flat or in various types of curves. (See, also, page 886.)

Corr-Mesh. Corr-Mesh is manufactured by the Corrugated Bar Company, Inc., Buffalo, N. Y., which supplies, also, special clips for splicing and fastening the mesh to the supporting members. It is made in two types. One has ribs ¾ in high, spaced 3¾ in on centers; the other type has ribs ⁹⁄₁₆ in high, spaced on centers. For the ¾-in-rib Corr-Mesh the sheets are 13 in wide, and for ⁹⁄₁₆-in-rib Corr-Mesh they are 18 in wide. The mesh is furnished in United States standard gauges, Nos. 24, 26, and 28. Standard sheets are 6, 8, 10, and in length. No allowance need be made for side laps, but at least 2 in should allowed for end laps.

Duplex Self-Centering. The Sharon Steel Hoop Company, of Youngstown, Ohio, manufactures the Duplex Self-Centering. It is 23 in in width, is finished in lengths of from 4 to 12 ft, and in Nos. 24, 26, and 28 metal, United States gauge. It weighs 1.37 lb per sq ft for the No. 24 gauge, 1.03 lb for the 26 gauge, and 0.86 lb for the No. 28 gauge; and it has a corresponding cross-sectional area per foot of width, of 0.411, 0.308, and 0.257 sq in

Sectional Systems. During recent years, the UNIT SYSTEM OR SEPARATELY MOLDED SYSTEM, consisting of shop-made reinforced-concrete members, such as

girders, lintels, floor-slabs, and wall-panels, made at a factory and shipped to sites of building operations, has been receiving considerable attention in t country. This system is more completely discussed in Chapter XXIV, p 953, under the title Separately Molded Construction. Separately mol members have been used between the steel beams of fire-proof floor-construct as a substitute floor-filling for the usual terra-cotta or concrete floor-arc The advantages of such systems, where they are practicable, are obvious. S members are usually made as large as can be conveniently handled and of c paratively long span.

Disadvantages of Sectional Systems. The reason that the SECTION SYSTEMS have not found favor is because they necessitate a fairly uniform spac of beams throughout a structure, and this is generally impracticable. casting of the parts has hitherto not been commercially successful, as the for although used repeatedly, have been more expensive than the usual centel at the building; and it is also generally necessary to use a concrete that is ric and more carefully prepared in order that it may stand the additional handli Even with all possible care, the breakages in transportation are considera As the methods of manufacture of factory-made members are constantly be perfected, chiefly in mechanical contrivances for cheapening the forms and red ing the handling during the process of manufacture, the economy of this syst is being substantiated, and particularly when it is used in combination wit light structural-steel fire-proofed frame.

Waite's Concrete Beam. In Fig. 39 is shown a type of SECTIONAL FLO CONSTRUCTION that has been used in a number of buildings by the Stand

Fig. 39. Waite's Concrete I Beams

Concrete Steel Company of New York City. The floor-construction consists series of concrete I beams 10 or 12 in in depth, supported on the lower flange the steel beams, which are spaced from 5 to 7 ft apart. The concrete beams set about 18 in apart and the spaces between the lower flanges are filled in a cinder concrete of the same composition as the I beams. On the tops of concrete beams is placed a metal fabric of small mesh on which a lean-conc slab is laid. This makes a comparatively light floor-construction, becau the large spaces between the concrete beams. The concrete I beams are at the shop and allowed to harden before they are sent to the building. the lower flange is inserted, as shown, a steel reinforcement, of small circ or other cross-section, to furnish the necessary tensile strength. The be are cast with the proper lengths, in accordance with the drawings; and slight variations at the building are made up by filling the spaces between ends of the concrete beams and the webs of the steel beams, and covering webs of the latter with concrete. A similar construction, consisting of a s

beams, with lower flanges 1¼ in thick and 12 in wide and stems 2 in thick 12 in deep, of 1 : 4 cinder concrete, reinforced with ⁵⁄₁₆-in rods near the es, and without floor-finish of any kind, successfully withstood the fire, r, and load tests of the New York City Bureau of Buildings after having constructed 28 days. This system has proved to be practical in cases in h a flat or level ceiling is required and the steel floor-beams are 10 in or e in depth. The cost of construction compares favorably with that of r flush-ceiling types.

he Siegwart Floor System. This system (Fig. 40), designed by Hans wart, of Lucerne, Switzerland, is in extensive use in that country. The

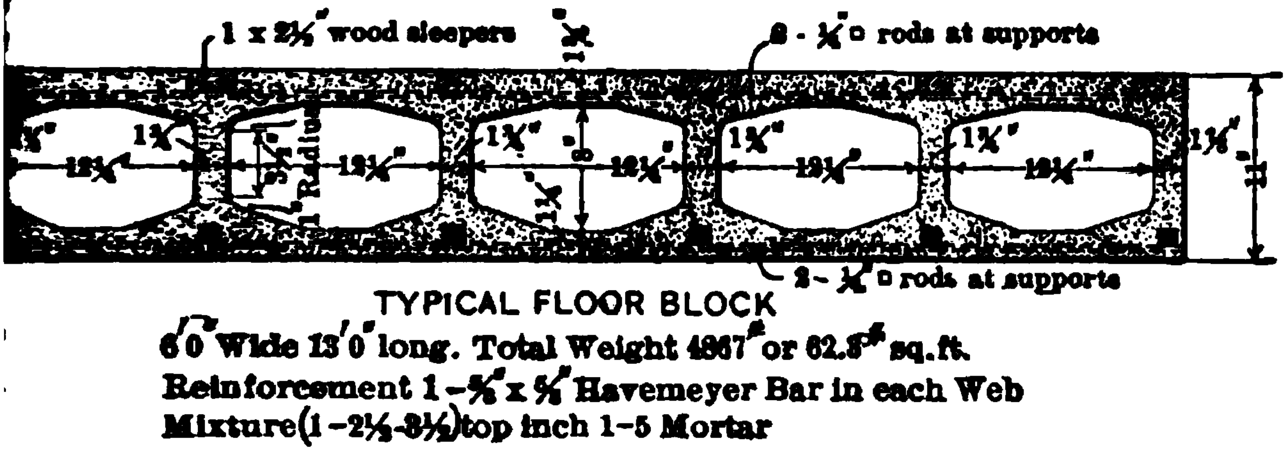

FIG. 40. Siegwart Reinforced-concrete Floor-construction

ional units are usually made 10 in in width, the height and reinforcement ying with the span and load. In a test on a beam of this type, designed to y a live load of 150 lb per superficial ft over a 16-ft span, the construction stood a satisfactory four-hour fire test with a load of 150 lb per sq ft, followed r the fire by a test with a load of 600 lb per sq ft. It is claimed for this em, that using the same working units for the strength of the material, the l weight of the construction is only one half that of a monolithic reinforced-rete floor designed to carry the same load with the same percentage of forcement. "The Siegwart Company claim their method to be much per than monolithic floors. From quotations furnished by their Canadian pany, the price in Montreal is quite a little less than the author's expe-e for monolithic floors in the same city, ranging from 17 to 26 cts per sq ft, ed for various spans and loads."* A modification of the Siegwart system been developed by Grosvenor Atterbury, and has been employed in two-story three-story residence-buildings for the Sage Foundation Homes Company rest Hills (Long Island), N. Y.

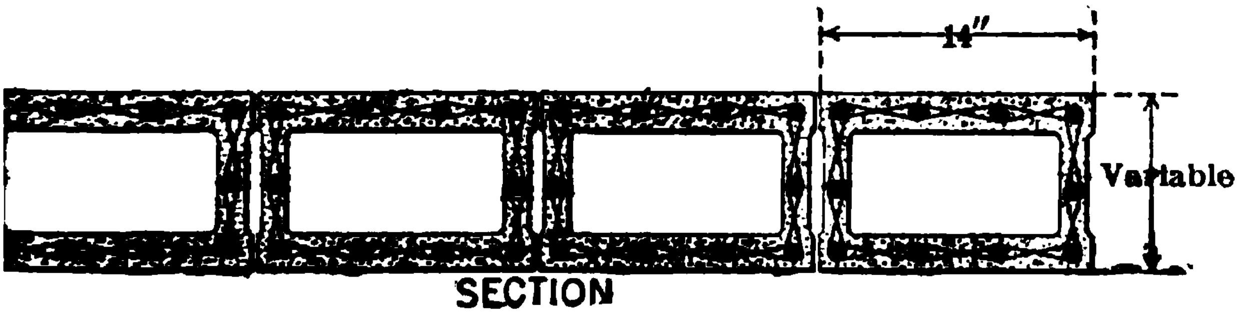

FIG. 41. Climax Reinforced-concrete Floor-construction

e Climax Floor System. This system (Fig. 41) was designed by S. M. lolph. The design is similar to that of the Siegwart floor system.

has. D. Watson, Concrete Construction with Separately Moulded Members and . Proc. Nat. Asso. Cement Users, Vol. VI, 1910.

The Vaughan Floor System. The Vaughan Company of Detroit, Mi is manufacturing a shop-made unit which is employed considerably throug the Middle West. The general form of this unit is like that of Waite's con beam, shown in Fig. 39.

The Watson Floor System. Two types of sectional floor systems for proof floor-fillings between steel beams are shown in Figs. 42 and 43. For

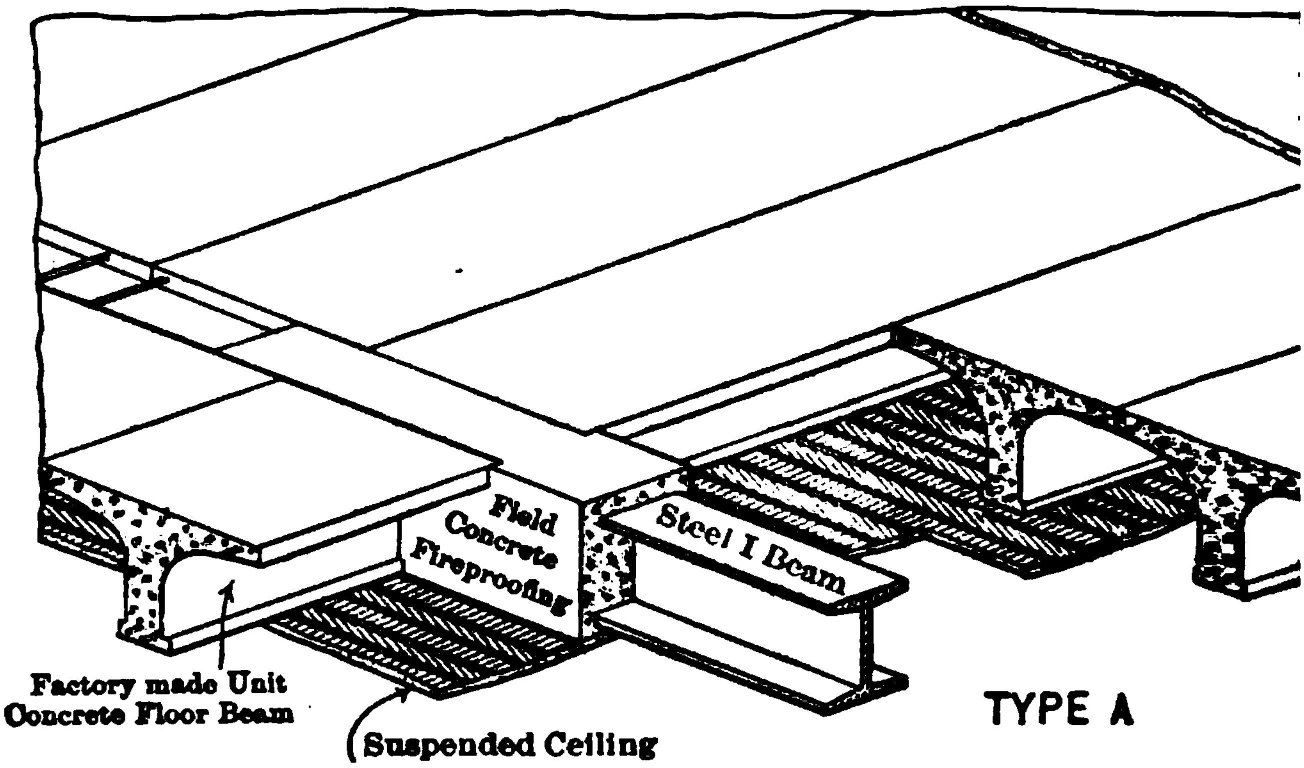

FIG. 42. Watson Reinforced-concrete Floor-construction. Without Slabs

spans and heavy loads, the T sections are used, laid side by side; and for s less than 20 ft and loads of 200 lb per sq ft or less, the beams are spaced on centers with flat slabs between. This system is controlled and installe the Unit Construction Company of St. Louis, Mo. Beams and girders

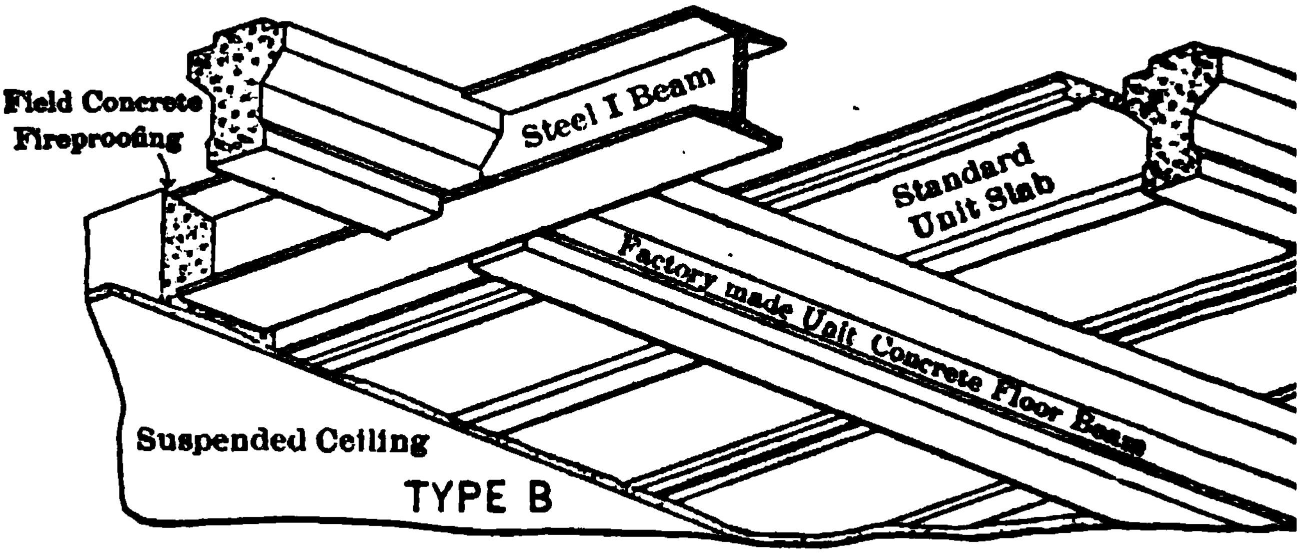

FIG. 43. Watson Reinforced-concrete Floor-construction. With Slabs

cast with unit frames in horizontal molds, and slabs are made on edge in forms. In the American School Board Journal for August, 1912, Theodo Skinner describes the construction and erection of a story-and-basement sc house with a structural-steel frame and shop-made reinforced-concrete j with unit-ribbed reinforced-concrete slabs.

Gypsum Floors. Gypsum has been extensively used for floors and ro fire-proof buildings. It furnishes a light construction which, with the additi

ntage of the rapidity with which it can be put in place, is economical not y with respect to the floor itself but also on account of a saving in the amount he structural steel supporting it. Another favorable feature is the great t-insulating property of gypsum, resulting in absence of condensation and a ction in the cost of heating the building.

he Metropolitan System. This construction consists of a series of steel les suspended from the supporting steel beams and encased in a slab of pure fined gypsum containing about 15% of wooden chips. The cables are generally posed of two No. 12 galvanized-steel wires, twisted. They are made contin- s over the supports, being securely fastened over the flanges of the end-beams hannels by heavy S hooks or other suitable means. The cables are spaced from 3 in apart, depending on the carrying capacity desired. They are held taut a ⅝-in round steel rod, laid at the middle of the span at right-angles to their ection. The mixture of gypsum and chips is sent to the work in bags and ed on wooden centers, as in the case of concrete floors, wet, and allowed to . The sides and flanges of the supporting steel beams are encased in the same terial, all as shown in Fig. 44. The minimum thickness of floor-slabs is 4 in;

F

Fig. 44. Metropolitan Fire-proof Floor

usual thicknesses for roofs are 3 and 3½ in The finished slabs weigh about per sq ft per in in thickness. Spans of from 6 ft 6 in to 7 ft are said to make most economical arrangement, all things considered. Spans should not eed 10 ft. The safe gross strength of the construction may be determined the formula,

$$w = \frac{24Td}{bL\sqrt{9L^2+d^2}},$$

hich

=the safe gross load per sq ft of floor or roof-surface, in pounds;

=the safe tensile strength of the twisted cables, in pounds, which for the ordinary case of two No. 12 cold-drawn steel wires, may be taken at 365 lb;

=the deflection of the cable, in inches, and equals the slab-thickness less the sum of the protection of the cables at the center of the slab and over the supports, that is, ordinarily, the slab-thickness less 1 in;

=the spacing of the cables, in inches;

=the span, or distance, between centers of supports of the slab, in feet.

o tie-rods are necessary in this floor-construction; but in the end-bays, when lateral stiffness of the beams together with the compressive strength of the -slab is not sufficient, struts must be provided of such size and spacing as necessary to resist the pull of the cables. This floor-construction is con- d and installed by the Keystone Gypsum Fireproofing Corporation, New

Metal Lumber. A system of pressed-steel I joists, channel-joists, co joists, wall-ribbons, etc., has been developed as a substitute for ordinary wo framing in the construction of walls, floors, roofs, and partitions. In the construction, the I joists and channel-joists, of from No. 16 to 12 United St gauge sheet metal, are braced by metal bridging, to give additional rigidity. typical floor-construction is shown in Fig. 45. The steel floor-joists are cov above with a concrete slab reinforced with expanded-metal lath, and the l flanges are protected by a ceiling of metal lath and cement plaster attache the joists by means of the prongs. The metal-lumber joists frame into ordi steel girders, resting on a shelf-angle as shown in the drawing. The joists cut to length at the factory, properly marked and tagged and, with the erect diagrams, are shipped to the site. All joints and splices are riveted in the f The steel girders should be properly incased in some fire-proof covering.

Fig. 45. Berger's Metal Lumber and Concrete Floor-construction

materials for this floor-construction are manufactured by the Berger Manu turing Company, Canton, Ohio; the General Fireproofing Company, You town, Ohio, the Truscon Steel Company, Youngstown, Ohio; and the Nati Pressed Steel Company, Massillon, Ohio. They publish safe-load tables metal-lumber I joists and channel-studs for spans of from 4 to 20 ft. This tem, contemplating the use of steel joists and girders, not thoroughly inc with fire-proof materials, cannot ordinarily be considered thoroughly resistant, although a specially constructed floor with all the steel covered protected with fire-proofing-material has passed the fire test prescribed by New York Building Code. (See page 827.) It has been extensively use replace combustible building-construction, especially in residence-buildings.

Protection of Girders and Beams. No form of floor-construction ca considered thoroughly fire-proof unless it includes a protection of the l flanges of all steel beams and girders, or provides for the protection of all used in its construction or support. The material used for the protective co ing is generally the same as that used in the floor-construction itself.

ncipal materials are tile, either dense, porous, or semiporous; gypsum; and ncrete, either of cinders, stone, or slag Beam-protection, where the floor-nstruction incases the side of the beams, as in Figs. 17, 19, or 34, should ver be less than 1 in thick Where paneled ceilings are used, that is, where e lower part of the beams is below the lower side of the floor-construction, in Figs. 18 or 30, the protection should be increased to at least 1½ in at all nts.

Tile Beam-Protection. When tile is used, there are two types of protec-n. In one case the blocks incasing the bottom flanges of the steel beams meet

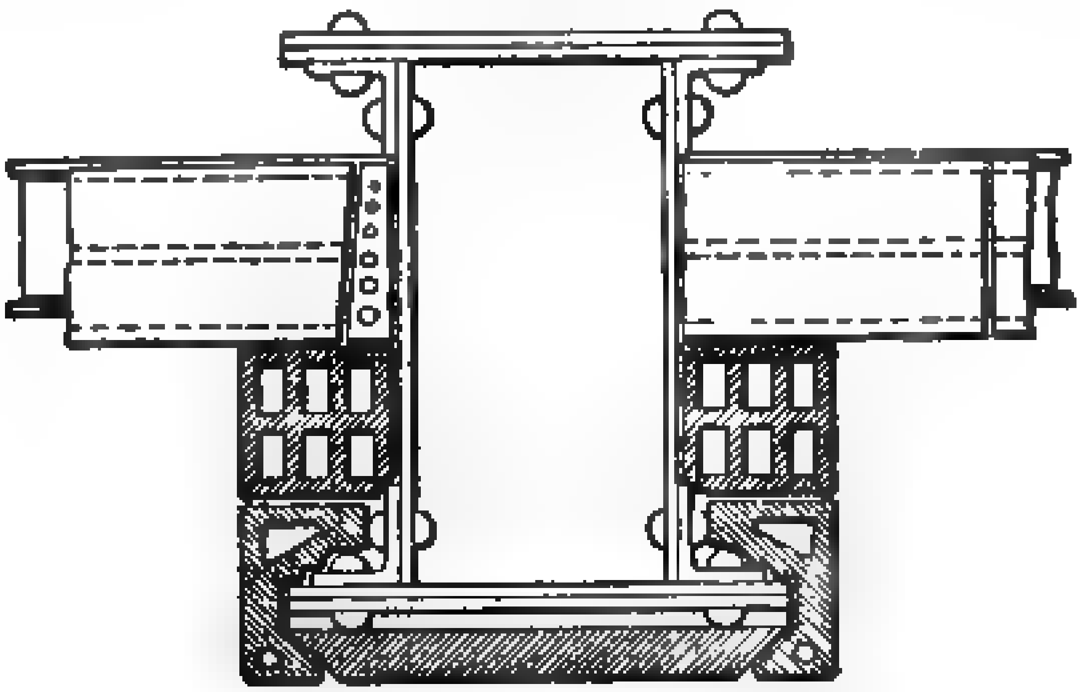

Fig. 46. Tile Protection for Box Girder

the middle of the lower side of the flanges; in the other, they simply turn er the edges of the bottom flanges and hold flat tiles with beveled edges

Fig. 47. Tile Protection for Single-beam Girder

at the lower side of those flanges. The latter is considered the better d, although in this method the danger of breakage of the part extending

under the flange is supplemented by the possibility of an omission of the protection-tiles. The blocks incasing the lower flanges may be the skewb of the arch, or they may be separate blocks. Different forms and condition illustrated in Figs. 15 to 24. Fig. 26 shows the entire beam protected by bl on both sides. Girders, which often project below the ceiling-line, are m more exposed to the effects of fire and water than the floor-beams, and should have, therefore, the most efficient protection. As a rule, such gi should be provided with not less than 4 in of terra-cotta protection at the s and 1½ in of solid tile on the lower side, with a space of ½ in between the t cotta tiles and the girder. Fig. 46 is a typical method of protecting girder means of hollow tiles. The bottoms of the skewbacks are prevented f spreading by wire ties placed in ~~the end-joints between~~ the soffit-tiles and ho into the round holes in the skewbacks. Single-beam girders are usually tected as shown in Figs. 22 and 47, the latter figure showing more particu the protection of a beam at the side of an opening in the floor.

Concrete Beam-Protection. A more thorough incasing of the webs lower flanges of beams and girders can be accomplished by the use of conc The superior fire-proof character of cinder concrete makes it the best mat for this purpose. If of sufficient thickness and properly applied, it will securely, without reinforcement, around the flanges of beams and gir But where it is less than 2 in thick, wire or metal lath, wrapped around flanges, should be embedded in it. A common form of concrete-protecti shown on right hand side of Fig. 30. Sometimes the soffit of the beam is tected by a concrete slab with an insulating air-space. This method is one may be advantageously used for the protection of girders. A fire test of form of girder-protection made in the Butterick Building, New York thoroughly established its efficiency. Hung ceilings are sometimes used a protection for the steel beams. This is very bad practice, as these cei are more than likely to collapse in a severe fire. The experience in the timore fire confirms this belief. (See, also, pages 780 to 782.)

The Fireproofing of Trusses. When steel trusses are used to suppor roof or several stories of a building it is very important that they be prote not only from heat sufficient to warp them, but also from expansion suffi to affect the vertical position of the columns on which they are supported. following description of the covering of the trusses in the Tremont Te Boston, Mass., furnishes a good illustration of the way in which this shou accomplished: "The steel girders were first placed in terra-cotta blocks o sides and below, these blocks being then strapped with iron all aroun girders, and upon this was stretched expanded-metal lathing, covered w heavy coating of Windsor cement; over this comes iron furring, which rec a second layer of expanded-metal lath, the latter, in turn, receiving the fin plaster. There is, consequently, in this arrangement for fire-protection, a dead-air space, then a layer of terra-cotta, a Windsor cement covering, an dead-air space, and finally, the external Windsor cement." Numerous s of terra-cotta tiles are made for incasing the structural shapes commonly in steel trusses. Some of these are shown in Fig. 48. The tiles should a be secured in place by metal clamps passing entirely around the envelo better still, by wrapping with wire lath. The tiling should then be plas with hard wall-plaster. Trusses, also, may be fire-proofed by complete casing the several members in cinder concrete, either with or without reinforcement. The method of incasing steel columns by means of the ce gun (page 826) is also applicable to the protection of steel trusses, and if o ficient thickness would probably serve as a suitable fire-protection; b

ble data on this latter point are as yet available. When trusses are to be proofed, the additional weight must be provided for in the strength of the es themselves.

SECTION OF STRUT

FIG. 48. Tile Protection for Members of Steel Trusses

Steel Framing for Fire-proof Floors. Before the framing-plans of a build- can be made, it is necessary to decide, in a general way, upon the SYSTEM FLOOR-CONSTRUCTION or fireproofing that will be employed. Thus, if any one the LONG-SPAN SYSTEMS, such as the Herculean, Johnson, and many of the crete systems, is to be adopted, the girders should be spaced so that the r-construction will span between them, without floor-beams, as shown Fig. 49, while if an ORDINARY FLAT-TILE ARCH is to be used, floor-beams will

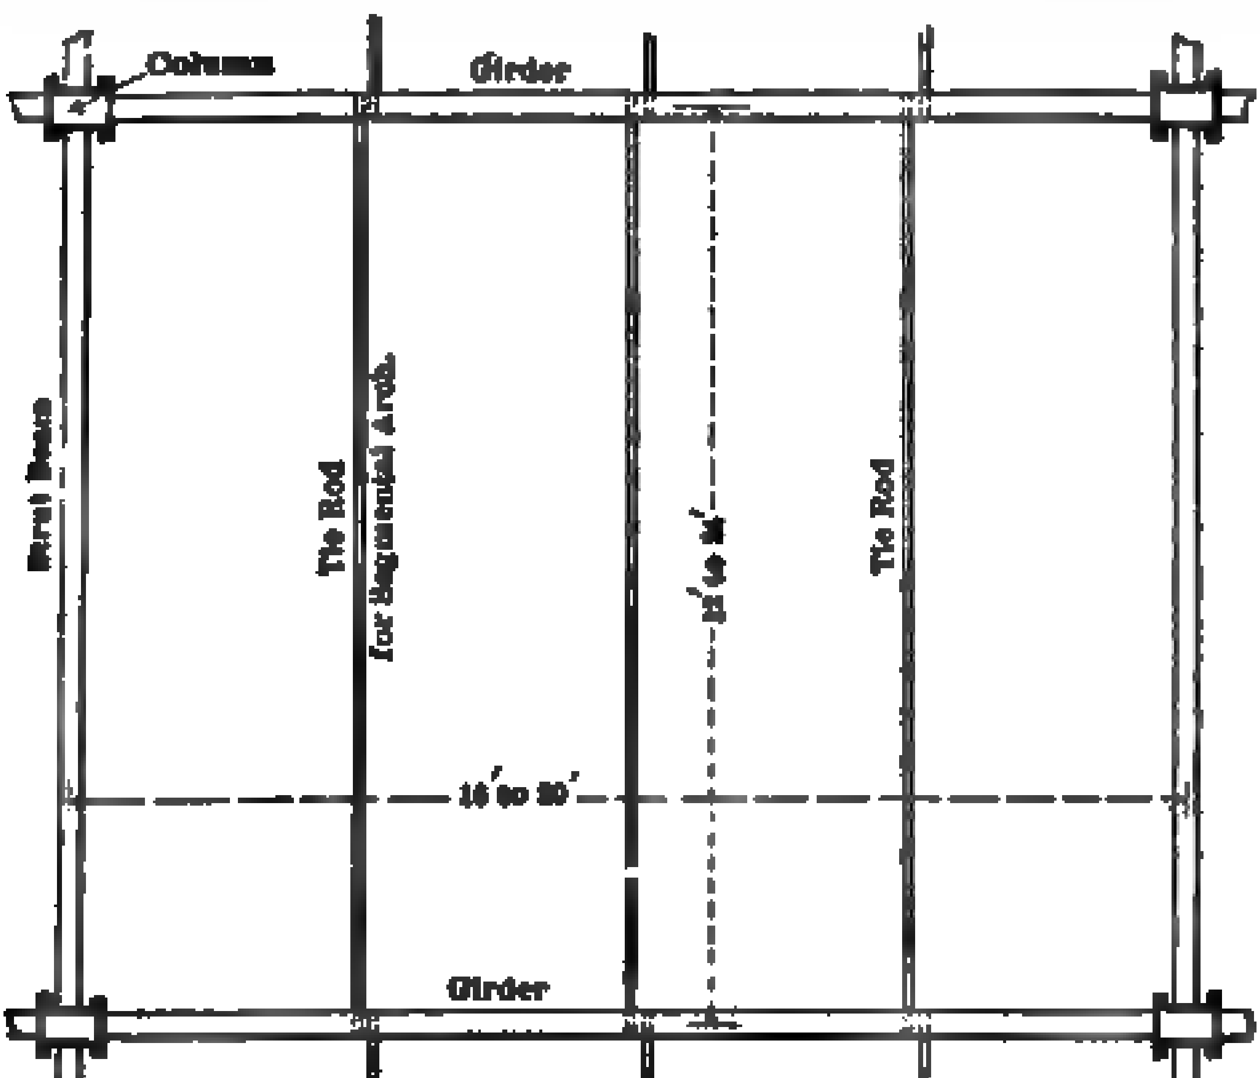

Fig. 49. Steel Floor-framing for Long-span Construction

be required, spaced from 5¼ to 9 ft apart, and these beams must be suppo
by girders, as indicated in Fig. 50. When there are no floor-beams, a stru
BEAM should be riveted between the columns, as in Fig. 49, to hold the la
in place during erection and to stiffen the building. It should be remembe
that with floor-beams spaced not more than 7 ft on centers, almost any sys

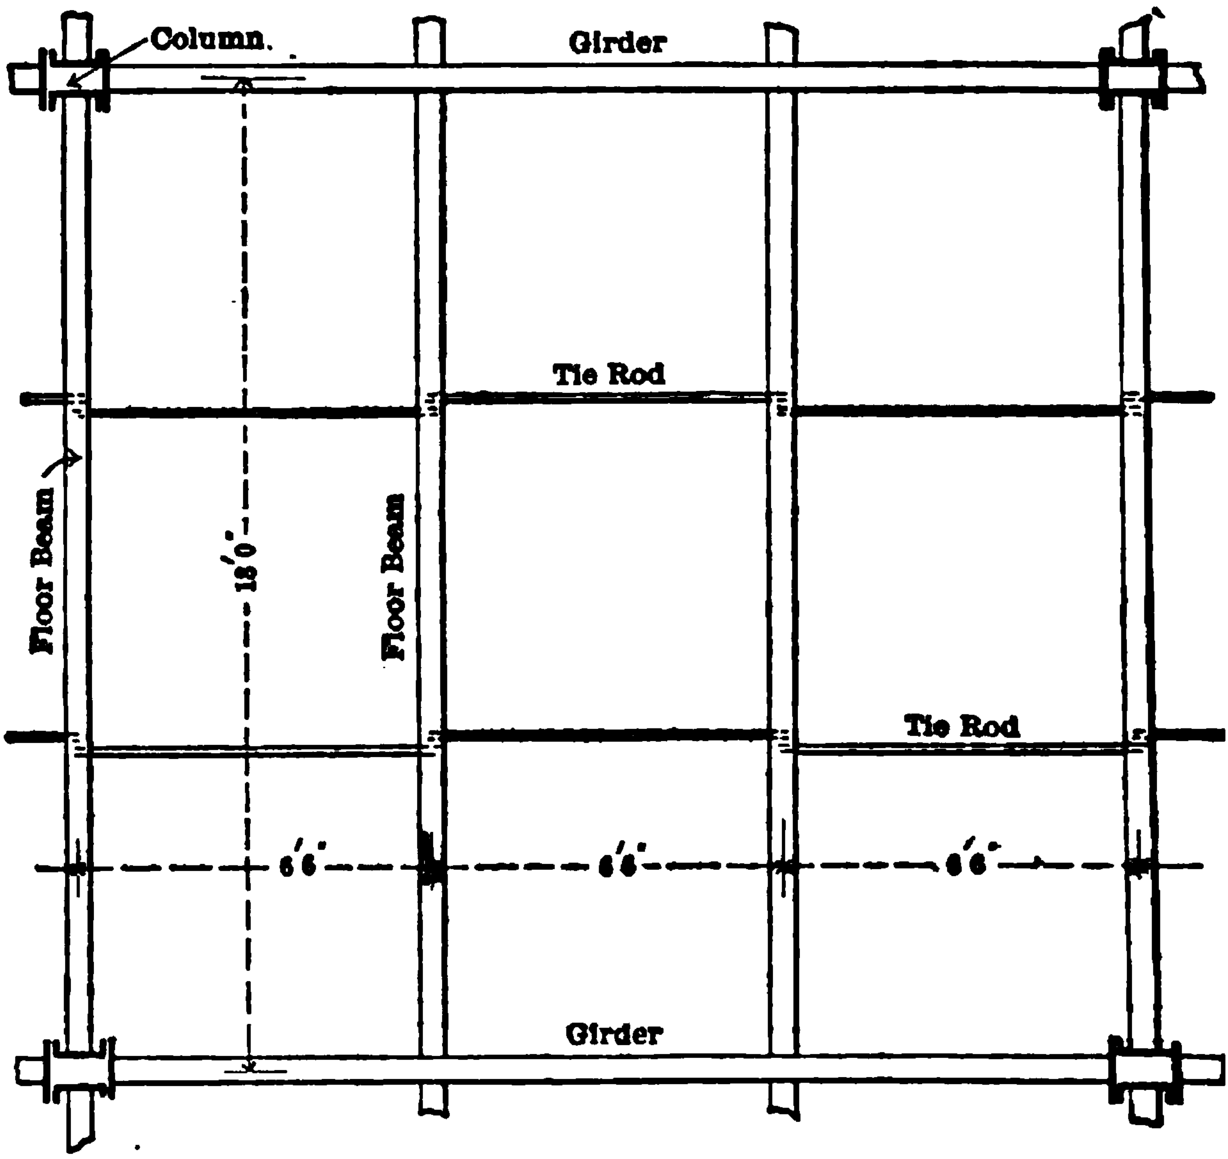

Fig. 50. Steel Floor-framing for Short-span Construction

of floor-construction may be employed; while if the floor-beams are omi
there are few systems to select from. With any form of filling between b
or girders, less steel is required for moderate than for excessive spans of b
or girders.

Computations for the Steel Framing. The computations for the
beams and girders of a fire-proof floor are very much the same as for a wo
floor. The load or loads which any given beam is required to support are
estimated and then the beam of the necessary size to support the load is sele
The DEAD LOAD for any fire-proof floor may be estimated with sufficient accu
by means of the data given in this chapter in connection with the diff
systems of floor-construction. The dead load should include the weight o
beams, the fireproofing, including all concrete filling, the plastering, fu
lathing, nailing-strips, and flooring. The LIVE LOADS may be estimate
means of the data given in Chapter XXI, pages 718 to 721.

Example. The best arrangement for the columns in a retail store is 1
them 18 ft on centers in one direction and 19 ft 6 in in the other. It is de
to run the girders as shown by Fig. 50, and to put a beam opposite each co

d two beams between the columns. It is required to determine the proper es of the beams and girders, using an ordinary end-arch construction between e beams

Solution. From Table VII, page 836, we find that the least depth of arch hich it is advisable to use is 10 in, but as we will probably have to use 12-in eams it will be better to figure on a 12-in arch, as this will give less filling n top. The weight of the 12-in arch will be about 39 lb per sq ft. We shall obably require 2 in of concrete filling on top, which will weigh 16 lb, and ½ in of light filling between nailing-strips, weighing, say, 9 lb per sq ft. The oring and nailing-strips will weigh about 4 lb, the plastering on the ceiling lb, and we must allow at least 6 lb per sq ft for the weight of the beams themves. These make a total dead weight of 79 lb per sq ft. The live load for retail store should be taken at 150 lb per sq ft, making a total load per square ot on the beams of 229 lb. The total load that each beam must be capable of pporting will be 6½ ft by 18 ft by 229 lb, or 26 793 lb, or 13.4 tons, which is umed to be uniformly distributed. From Table IV, page 580, we find that is load, with a span of 18 ft, will require either a 12-in, 45-lb beam, or a 15-in, 2.9-lb beam. The latter will be both stronger and cheaper, but will increase e thickness of the floor by 3 in and require additional filling.

The girder must support two concentrated loads of 26 793 lb or 13.4 tons ch. On page 566 it is stated that when a beam supports two equal loads plied at points one-third the length of the span from each end, the equivalent iformly distributed load may be found by multiplying one load by 2⅔. ultiplying 26 793 lb by 2⅔ we have 71 448 lb as the equivalent distributed d on the girder, to which should be added the weight of the girder. This quires a standard 24-in 79.9-lb beam (Table IV, page 577).

If instead of using tile arches between beams 6½ ft apart, we conclude to e the Herculean or Johnson construction spanning from girder to girder, we uld frame our floor as in Fig. 49. For this span we should require 10-in tiles, ighing 55 lb per sq ft. Allowing 8 lb for 1 in of concrete, 9 lb for filling, 4 lb flooring and strips, and 5 lb for plastering, we have 81 lb as the dead load per are foot. We have added nothing for the weight of the girder, as this will fully offset by the portions of the floor not loaded. The live load per square t will be 150 lb as before, and the total load to be supported by the girder, ft by 19 ft 6 in by 231 lb, or 81 081 lb, or 40.54 tons, which will require a in 79.9-lb beam (Table IV, page 577). Hence by this arrangement we save weight of the floor-beams; but a 6-in strut-beam should be placed between columns, as in Fig. 49. The calculations for any other floor-construction similar to the calculations for this example, the only variations being in figuring of the dead weights of the construction.

ables for Floor-Beams. It is a difficult matter to prepare tables that may enerally used, showing the size of steel beams required for fire-proof floors, use such beams are often irregularly spaced, and there is a wide variation e dead loads. The following tables, however, may be used in making approxe estimates and in checking the computations for any particular floor. The of I beams given may be safely used where the total live and dead loads ot exceed the values given in the headings. The total loads should include ient allowance for the weights of any partitions that the floor-beams may lled upon to support.

ble XIII gives the sizes and weights of I beams for floors of offices, s, and apartment houses; Table XIV, for floors of retail stores and asly-rooms; and Table XV, for floors of warehouses. The total loads used computations are, respectively, 120, 200, and 270 lb per sq ft.

e-Rods. In all segmental arches and other types in which a thrust is ted against the beams, TIE-RODS must be provided to prevent the beams being pushed apart, and especially to prevent the outer bays from spread- They should run from beam to beam from one end of the floor to the . If the outer arches spring from an angle, as in Fig. 14, the tie-rods in bay should be anchored into the walls with large plate-washers. The ds should be located in the LINES OF THRUST of the arches, which are arly below the half-depth of the beams, and in some cases near the bottom es. If their appearance is objectionable, they should be hidden by a hung g. For constructional purposes they are desirable in all types of floor-ruction, even though the floors do not exert a thrust on the beams. rule tie-rods are proportioned and spaced according to some RULE OF B rather than by actual calculations of the thrust. For the interior arches ractice is probably safe enough, but for outside spans, and particularly gmental arches, the thrusts of the arches should be computed and the proportioned accordingly. The spacing of the rods is generally eight the depth of the supporting beams, but never more than 8 ft. For interior e arches, the following rule can usually be safely followed: for spans of less, use ¾-in rods spaced about 5 ft apart; for 7-ft spans, ⅞-in rods, art; and for 9-ft spans, ⅞-in rods, 4 ft apart.

HORIZONTAL THRUST of an arch may be found by the following formula:

$$T = \frac{3\,wL^2}{2\,R}$$

in which

T = pressure or thrust in pounds per linear foot of arch;
w = load on arch in pounds per square foot, uniformly distributed;
L = span of arch, in feet;
R = rise of segmental arch, or effective rise of flat arch, in inches.

The RISE of a segmental arch is measured from the springing-line to the so of the arch at the middle. For flat hollow-tile arches, the effective rise may figured from the top of the beam-flange to the top of the tiles. As the ti usually project from 1½ to 2 in below the bottom of the beams, the effecti rise will be from 2 to 2½ in less than the thickness of the arch. For the inter arches of a floor, w may be taken for the live load only, but for the exter arches, w should include both the full dead and live loads. Having found thrust of the arch, the SPACING OF THE RODS of any particular size may readily determined by dividing the safe load given for that size of rod in table on page 388, allowing 16 000 lb UNIT STRESS, by the thrust. The res will be the spacing in feet.

Example. What size of tie-rods and what spacing should be used for floor-construction described on page 863, in the preceding example?

Solution. The depth of a tile arch is 12 in, the dead load 79 lb and assumed live load 150 lb. The span between the beams is 6½ ft. Then, the interior arches, $w = 150$ lb, $R = 12 - 2\frac{1}{2} = 9\frac{1}{2}$ in, $L = 6\frac{1}{2}$ ft and T $(3 \times 150 \times 42.25)/(2 \times 9\frac{1}{2}) = 1\,000$ lb. The tensile strength of a ¾-in rod, upset, at 16 000 lb per sq in, is, from Table II, page 388, 4 832 lb. Div ing this by 1 000 we have a little less than 4 ft 10 in as the spacing. T tensile strength of a ⅞-in rod is given as 6 720 lb, which would admit of a sp ing of a little more than 6 ft 8 in. For the outer spans, w should be taken $150 + 79 = 229$ lb. Then $T = (3 \times 229 \times 42.25)/(2 \times 9\frac{1}{2}) = 1\,526$ lb. this thrust we should use ⅞-in rods spaced about 4 ft 5 in apart.

Load-Tests. It may be desirable at times to test fire-proof floors after th have been installed. The same precautions should be taken as for tests on re forced-concrete construction, described on page 967. If it is desired to determ from such tests the ULTIMATE STRENGTH, a section of the floor of a width eq to the span should be cut loose from the rest and loaded to destruction, supporting steel beams being shored up during the test. The SAFE WORK LOAD is found by dividing the BREAKING-LOAD by the proper FACTOR OF SAFE

5. Fire-proof Roof-Construction

Flat Roofs. Flat roofs are constructed in the same way as the floors, exc that the beams and girders are set so as to give a slight pitch to the roo drain the water. As the ROOF-LOADS are usually less than the FLOOR-LOADS as there are no partitions to be supported, the arches or roof-panels are usu considerably lighter than the floor-panels, but the general construction is pr tically the same for both. When the roof is formed of reinforced conc the beams may be set so that the concrete will give the desired inclina to the roof and will have a nearly uniform thickness, as this reduces the am of concrete required, and also the weight. In cases where level ceilings are sired, however, it would be cheaper to set the roof-beams level and to gi the roof with dry cinders, as the cost of the hung ceiling would more than ci the cost of the extra construction necessary to take the added weight of cin fill. If the roof is to be covered with tin or copper, nailing-strips should be bedded in the concrete, as for wooden floors, and the entire roof sheathed. is claimed that tin or copper laid over terra-cotta or concrete will rust out few years.* Gravel or tile roofs may be built without woodwork of any k Whether terra-cotta, gypsum tile, or concrete is used for the roof-panels, sides and bottoms of the steel beams and girders should be efficiently prote

* Freitag.

well as all columns and all other structural metal in the roof-space. In ordinary building, in which there are stair-wells or elevator-wells, the roof d upper ceiling are likely to be more severely tested by heat, in case of fire, an any of the floors below, and experience has shown that this part of the build- g often has the poorest protection.

Pitched Roofs. Pitched roofs may be constructed in various ways, accord- g to the material that is to be used and the kind of roofing that is to be em- oyed. When terra-cotta or gypsum tile is to be used for the fireproofing, the st common method of construction is that which involves the framing of the of with I-beam rafters and T-iron purlins, set horizontally and spaced 1 in ther apart than the lengths of the tile. Between the tees, book tiles, or roofing- ts are placed as in Fig. 51, and the roofing is applied directly to the surface of

Fig. 51. Tile Fireproofing for Roof-construction

e tiles. If the roofing is to be of slate or of clay tiles, solid, porous terra-cotta cks should be used between the tees, as nails are held better by solid blocks an by hollow tiles; gypsum roof tile is also suitable for this purpose The ne construction may be used for flat roofs; but on account of the expense of e tees it will usually be more expensive than the construction above described, d not as strong or desirable. With the construction shown in Fig. 51, it is possible, by any economical method, to efficiently protect the bottom of the irons from the effects of heat. Reinforced-cinder concrete, or reinforced ous terra-cotta tile, Johnson System, affords an excellent and also an nomical construction for fire-proof pitched roofs. Either of these construc- ns may be filled between or on top of the rafters without the use of purlins, ept about once in from 6 to 10 ft, to prevent sliding and to stiffen the roof. hree-inch plates of concrete, with expanded metal embedded, have been essfully used in spans of from 6 to 7 ft and in some cases even in 8-ft spans. e concrete is deposited on wooden centerings, as in the floor-construction, . the upper side is smoothed off during the setting and floated smooth and ight to receive the roof-covering"* The roof-covering, usually slate, or

* Freitag.

clay tiles, may be nailed directly to the concrete, as nails are held nearly well by cinder concrete as by wood. This applies only to cinder concrete, as is quite impossible to nail into rock concrete or gravel concrete. In concr roofs the rafters, also, should be surrounded with concrete held in place

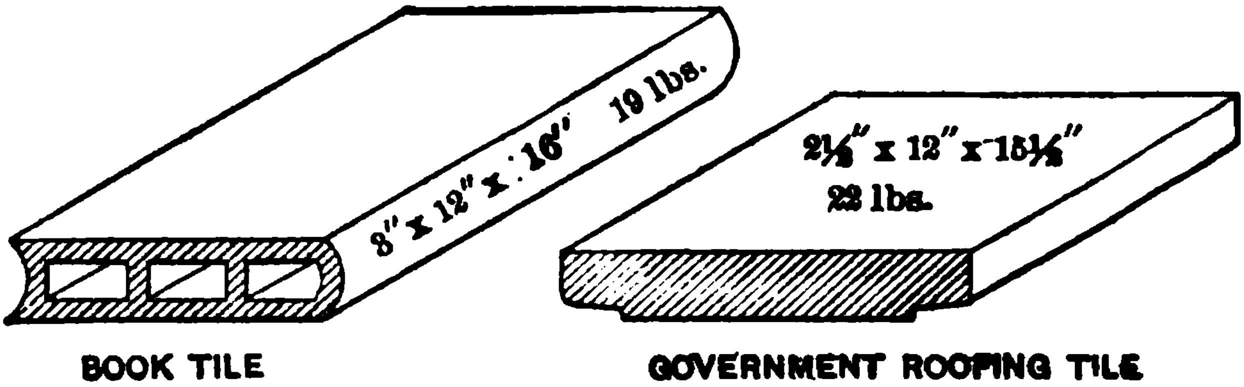

FIG. 52. Hollow Book Tile and Solid Tile for Roofs

metal lath. With terra-cotta roofs, the beams should be incased with ter cotta blocks. Fig. 52 shows the standard shapes of book tiles and solid roofi tiles. These are made 2, 2½, and 3 in thick, and from 16 to 24 in long. Thr inch book tiles weigh about 13 lb per sq ft, and 2½-in solid tiles about 16

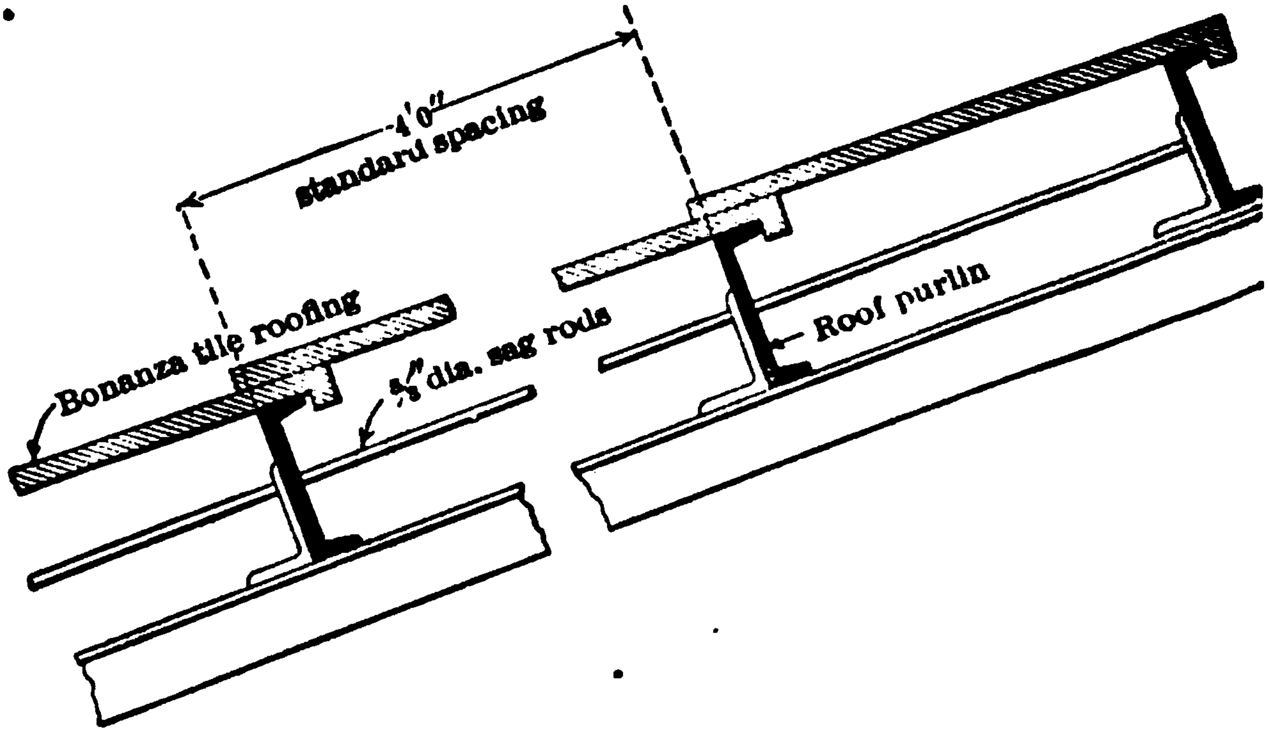

FIG. 53. Bonanza Reinforced-cement Tiles for Pitched Roofs

per sq ft. Tiles of both of these shapes are also used for ceilings and whe light, fire-proof filling is required.

Reinforced-Cement Tiles. Cement tiles of interlocking types, made in factory and reinforced with metal fabric or mesh, may be laid without sheatl directly on steel purlins. This type of construction, however, is suitable as a semifire-resisting roof-covering, as it is usually made with plates of ins cient thickness and does not contemplate the thorough incasing of the s understructure with concrete or other fire-resisting materials. Bonanza Cem Tile roofing is a type of this shop-made tile and is manufactured and contro by the American Cement Tile Manufacturing Company, Pittsburgh, Two types of tiles are made, one for pitched-roof and the other for flat- construction (Figs. 53 and 54). The properties of the tiles are given in the lowing tabulation:

Standard, Pitched-Roof Tiles

Thickness of tiles	about 1 in
Over-all dimensions of tiles	26 by 52 in
Tile-surface exposed to weather	24 by 48 in
Number of tiles per 100 sq ft of roof	12½
Weight of tiles per 100 sq ft of roof	1450 lb

Standard, Flat-Roof Tiles

Width of tiles	24 in
Length of tiles	60 in or less
Thickness of tiles	1½ in
Weight of tile-construction	16 lb per sq ft

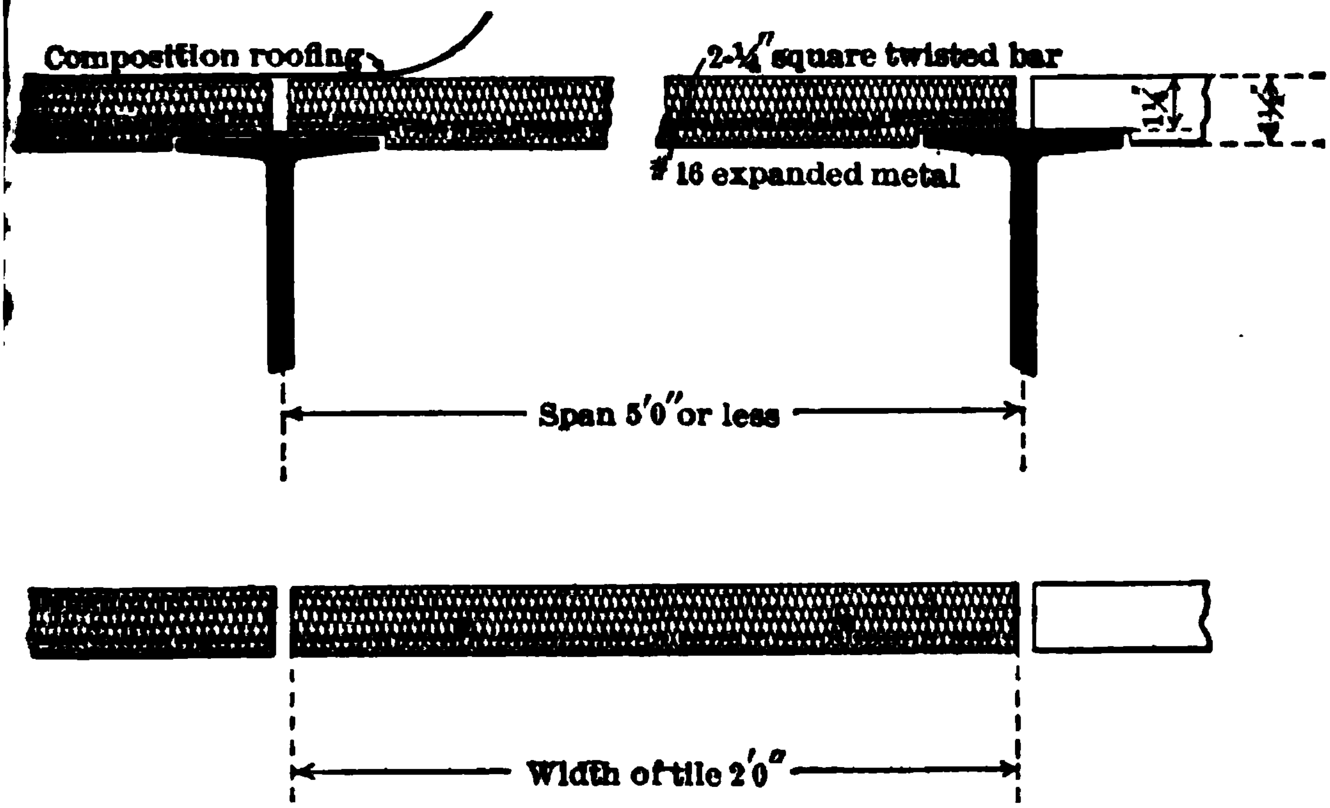

Fig. 54. Bonanza Reinforced-cement Tiles for Flat Roofs

The flat-roof tiles are designed for and have been used in connection with buildings for manufacturing-plants on spans of 5 ft between purlins. On these spans they have been tested up to an ultimate live load of 250 lb per sq ft. The top surfaces of these tiles are finished in a weather-proof and water-proof material of a dark, terra-cotta-red color.

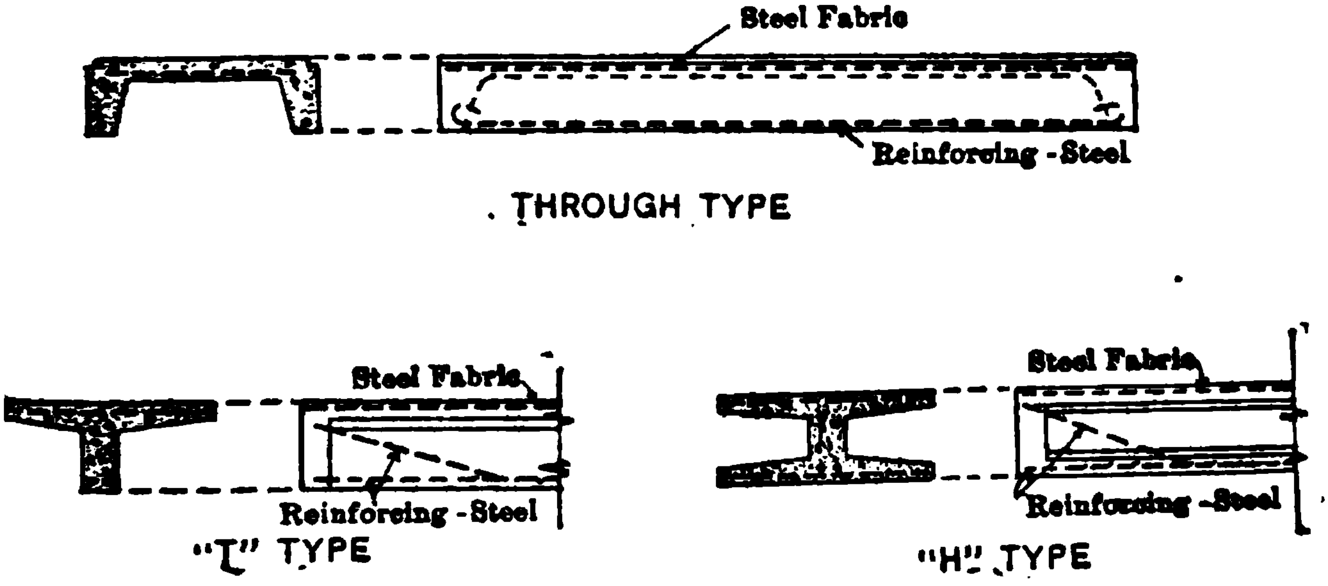

Fig. 55. Structolite Roof-tile

Structolite Roof-Tile. Shop-made roof-tiles made of a dense quick-setti gypsum cement, called STRUCTOLITE by the manufacturers, are put on the mark by the United States Gypsum Company of Chicago, Ill. The material used said to have an average ultimate crushing strength of 2000 lb per sq in. As tl material weighs only 77 lb per cu ft, a very light roof-construction results. Tl tiles are reinforced with steel in much the same manner as reinforced concret and their strengths are figured by the same formulas, using working stress appropriate to the materials. For spans from 4 to 6 ft, a trough-like tile is use as shown in Fig. 55. For greater spans, up to 10 ft, the T TYPE and H TYPE tile are used, the latter when a continuous flat ceiling is desired. The tiles a placed directly on channel or I-beam purlins, but when the flanges of the purlii are less than 2½ in wide, bearing-plates should be inserted between the tiles ar purlins. The weights of the roof-tiles in lb per sq ft are as follows, the til themselves being generally designed for safe superimposed loads of 50 lb p sq ft.

Span, ft	Depth, in	Trough type, lb	T type, lb	H type, lb
4	5	14	....	....
5	5	14	....	....
6	5	15	13½	18½
7	6	....	14½	21
8	6	....	14½	21
9	7	....	16	22
10	7	....	16	22

Robertson Process. Under the name of ROBERTSON PROCESS FLOO the H. H. Robertson Company, Pittsburgh, Pa., make and install gypsum floo construction of the same general character and design as the Metropolitan Floo (page 857). They also manufacture pre-cast roof-tiles designed on the sam suspension-principle. The cables protrude about 2 in at the ends of the slab near the top surface. When set in place on the roof-purlins with their en abutting, the projecting ends of the cables of adjoining slabs are tied togeth by a device that draws them taut, thus effecting continuity. The tiles are ral betted at the ends where the cables emerge, and these rabbets are filled wit gypsum, covering over and protecting the cable-connections. The following a the standard sizes of roof-tiles:

3 in thick, 24 in wide, varying in length by 3 in, from 4 ft 0 in to 6 ft 0 in
3 in thick, 21 in wide, varying in length by 3 in, from 6 ft 0 in to 6 ft 9 in
3 in thick, 18 in wide, varying in length by 3 in, from 6 ft 9 in to 7 ft 0 in
3½ in thick, 15 in wide, varying in length by 3 in, from 7 ft 0 in to 8 ft 0 in
3½ in thick, 12 in wide, varying in length by 3 in, from 8 ft 0 in to 8 ft 6 in

The weight per sq ft is 14 lb for the 3-in tiles and 16 lb for the 3½-in tiles.

Mansard Roofs are usually framed with rafters, riveted or bolted to wal plates. The space between the rafters may be filled with cinder concrete, holl partition-tiles, or blocks extending from rafter to rafter, as in Fig. 56. Slat or tiles may be nailed directly to cinder concrete or to porous terra-cotta. Prol ably the best way to attach slates or tiles is to nail 1¼ by 2-in wooden strips t the outer face of the concrete or terra-cotta, set them at the proper distanc apart to receive the slates or tiles, and then plaster between the strips wit

...nt mortar. This gives a better nailing for the roofing, and the wooden ...s are not affected by fire until the slate is practically destroyed.

...oof-Coverings. The materials ordi...ly used for the roof-covering of fire...of buildings are: (1) tar and gravel; ...asphalt and gravel or sand; (3) vitrified ...a, bricks, or slate tiles over tarred felt. ...r and gravel, or asphalt felting and ...el or sand, offer the cheapest roof ...able for a fire-proof building; and ...n a good quality of felt and distilled ...h or the best grades of asphalt are ...d, make a very satisfactory covering. ...h roofs, however, require to be renewed ...ut every ten years. The roofing is put ... in the same manner as over wooden ...truction, the felt being laid directly on ... concrete. Probably the best flat roof ...t can be put on a building is one of ...ified or slate tiles, laid over five plys of ...ed felt. The felt is laid and mopped ... for a gravel roof, and the tiles are ...dded on the felt in cement mortar. Vitrified tiles, about 8 in square and ... in thick, are made for this purpose, and slate tiles, 12 in square by 1 in ...k. have been used. Flat, vitrified-brick tiles, also, are used. Gravel roofing ...uld not be used on roofs which have an inclination exceeding ¾ in in 1 ft. ...r pitched or inclined roofs, slates, clay tiles, or metal tiles may be used. ...y tiles are superior to slate when exposed to fire and are generally to be ...ferred to slate; this is especially true of some of the patent interlocking tiles. ...e, also, pages 1582 to 1587, and 1595 to 1599.)

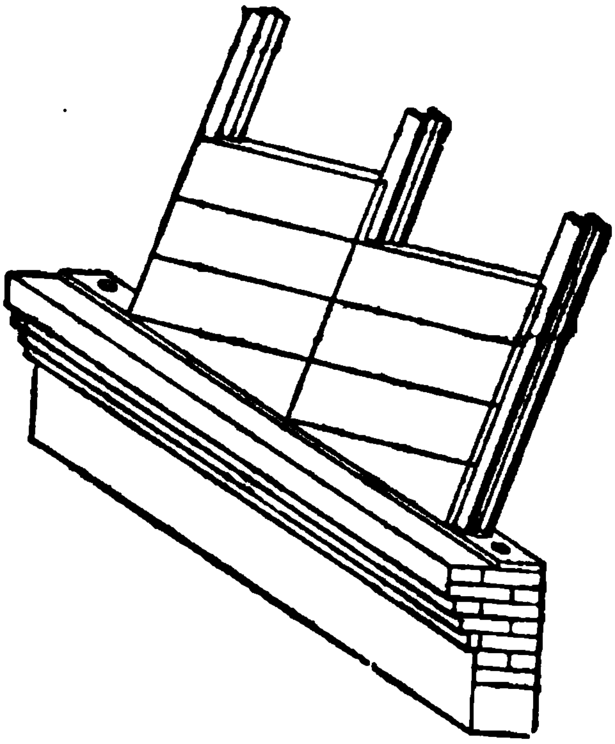

Fig. 56. Tiles for Mansard Roof

Suspended Ceilings. Office-buildings, apartment-houses, etc., having flat ...s, require ceilings below the roofs in order to make a proper finish in the

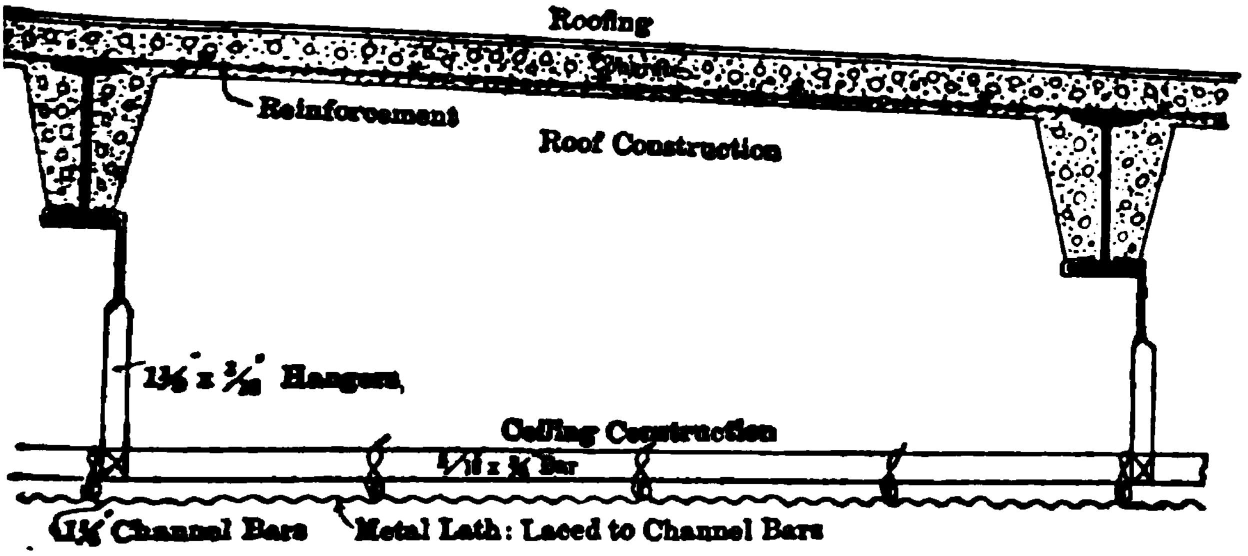

Fig. 57. Suspended-ceiling Construction

...s, and also for heat-insulation. In office-buildings the ceilings of the top ... are often framed and constructed like the floors, but with a lighter con...tion. More often the ceilings are suspended from the roof, as this requires ... less steel and is consequently much cheaper. It answers the purpose ... as well, that is, if the roof-beams are efficiently protected. Fig. 57 shows

a common construction for such ceilings. Wrought-iron hangers, about 1¼ 3/16 in or 1 by ¼ in, split at one end to hook over the lower flanges of roof-beams, are used to support 5/16 by ¾-in flat steel bars, spaced about 4 f centers; and to the under-side of these are laced ¾-in, ⅞-in, or 1¼-in chan 12 or 16 in on center receive the metal lat The bottom of each ha is bent at right-angle form a seat for the and the bar is laced to hangers. No bolting riveting is required, all nections being made lacing wire, or by ben the iron. Where stiffe wire lath is used, the c nels may be spaced 1 on centers; but if the dinary expanded laths used, it is better to p

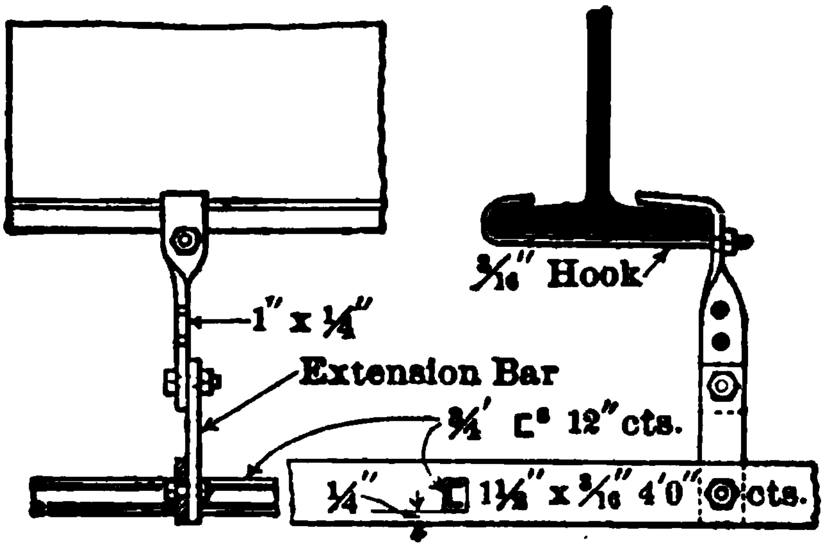

Fig. 58. Suspended Ceiling. Details of Two-bar System

the channels 12 in on centers. If ordinary lime mortar is used for plasterin 12-in spacing is really necessary. Another system is one which uses one set of horizontal bars, which are spaced close enough to receive lathing, and which are supported by hangers. With stiffened wire lathing, roof-beams spaced not over 5 ft apart, and short hangers, this may be the cheaper system; but without the stiffened lathing, there is no stiffness to the ceiling at right-angles to the bars. Where the hangers are 3, 4, or 5 ft long, and the spans between the beams

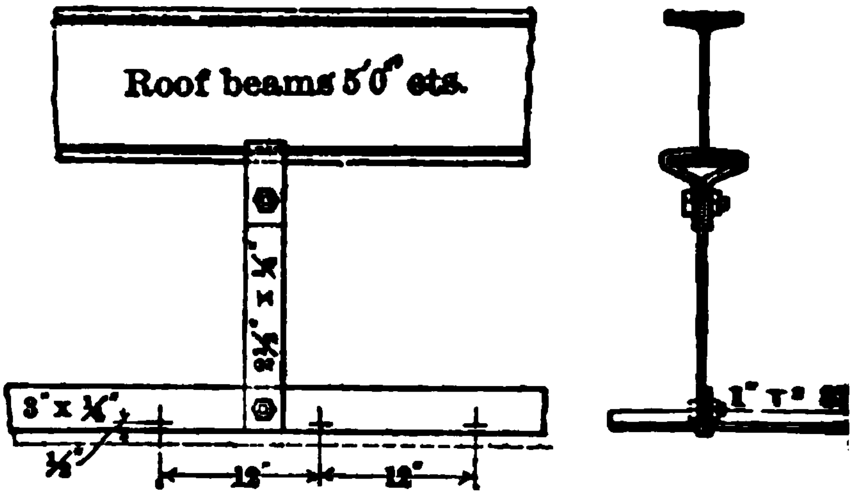

Fig. 59. Suspended Ceiling Details of Two-bar Sys

wider than 5 ft, the two-bar system, shown in Fig. 57, requires less steel, the reason that the channels, having spans of only 4 ft, may be made light, and only one third or one fourth the number of hangers are required. place of the small channels, small T bars or flat bars may be used, but when bars are held by lacing, channels are preferable.

Figs. 58* and 59* show very satisfactory details for the construction of two-bar system. Instead of the hook shown in Fig. 58, the hanger may split at the top, one half bending around one side of the beam-flange and other half around the other side. Where the ceiling is suspended below te cotta arches, toggle-bolts are used for the support of the hangers. The of the small bars supporting the lathing are usually spliced by means of sh iron clamps, about 6 in long, wrapped closely around the bars and hamm tight. For suspended ceilings under segmental or paneled floor-construc the same methods are employed, except that the hangers are replaced by holding the ceiling-bars close to the soffits of the beams.

* From Fire Prevention and Fire Protection, J. K. Freitag, pages 687 and 688.

6. Partitions and Wall-Coverings

equirement of Fire-proof Partitions. As a rule the partitions in fire-of buildings are not required to support any weight, but merely to serve the pose of dividing the spaces into rooms, and to confine a fire to the compart-nt in which it originates. No greater strength, therefore, is required in a tition than is necessary to carry its own weight. Rigidity, however, is re-red, and a rigidity in proportion to its height and unsupported length. When itions separate apartments or sections of a story, that is, when they are tically without window-openings or door-openings, they should be rigid ugh to prevent the passage of water from a hose-stream as well as the pass-of flame. In other cases this may be unnecessary; in fact, at times it may n desirable to construct partitions which can be easily removed to get at e spreading through doors or windows. The materials of partitions should incombustible. They should be poor conductors of heat. It is desirable, , to have them unaffected by water. Lightness is a good property, as any ease in the dead weight of the construction adds to the cost of the structure. titions should be as sound-proof as possible. Window-openings should be ided, when possible, in fire-proof partitions, and even door-openings should reduced in number to a minimum. In many buildings, however, in which s have no openings into streets or courts, such windows are necessary for ting the halls. When this is the case the frames should be made fire-proof, e-glass should be used, and, if possible, the sash made stationary.

Fire Tests on Partitions. In New York City no materials or types of con-ruction are permitted for interior permanent partitions in fire-proof buildings at have not met the required fire tests. The standard test of the American ciety for Testing Materials is based on the New York test.* Briefly, these ts require that the partition shall resist for one hour the destructive action of a ed fire, the heat of which has been gradually increased to 1700° F. during e first half-hour and maintained at that temperature for the balance of the e; and that it shall resist, also, for two and a half minutes at the conclusion of e fire test, the application of a hose-stream at 30 lb pressure.

Types of Partitions. Fire-proof partitions that are in common use may grouped, according to the materials or the method of construction used, as lows:

(1) Brick;
(2) Hollow tile or terra-cotta;
(3) Concrete (stone or cinder);
(4) Gypsum block;
(5) Plaster or concrete, with metal.

The choice of the materials and the type of construction are largely influenced the character of the building and the purposes for which it is used.

Partition-Walls. For bearing-partitions, that is, those which support floor-ms, there are probably no materials more satisfactory than brick and con-te. The latter may be used either in the form of blocks, or may be poured forms. Dense tile, also, is being used with satisfactory results for bearing-ls. Tests show a crushing strength, on net sections, equal to that of brick.

Hollow-Tile or Terra-Cotta Partitions. These are usually built of blocks, er square or brick-shaped, according to the particular product used. The are blocks are usually 12 by 12 in on the face, and the brick-shaped blocks usually 12 in long but vary in height. Both shapes are made in thick-

* See latest Year Book, Am. Soc. for Test. Mats.

nesses varying from 2 to 12 in. The 3-in, 4-in, and 6-in blocks are comm used, the 4-in blocks being the most popular for ordinary work. For more important partitions, such as stair and elevator-enclosures, not narrower than the 6-in blocks with the double row of cells should be u The blocks are commonly set with the voids vertical. Fig. 60 shows typ

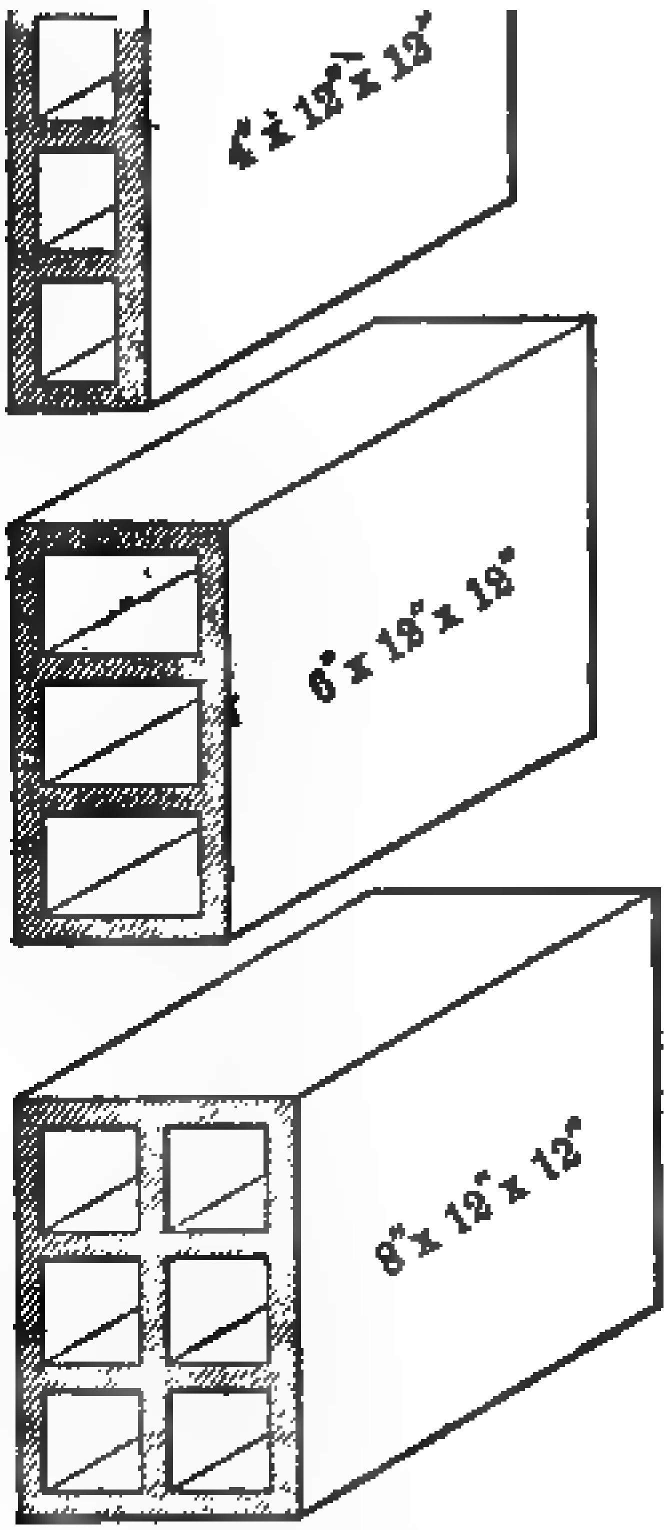

Fig. 60. Hollow-tile or Terra-cotta Partition-blocks

shapes of both the square and brick shaped blocks. Fig 61 shows ro cornered and angle-cornered partition-blocks, which must be set vertic "Terra cotta partitions of a 2-in thickness have been placed on the ma but have not been extensively used. A 2-in terra-cotta partition of any stre or efficiency is quite impracticable, and where floor-area is so valuable more space cannot be occupied, terra-cotta is not the material to be employe

* Freitag.

ugh the addition, however, of band-iron laid between the courses and ated under the name Phoenix,* the strength of a 2-in tile partition is greatly ased. The New York partition, Bevier Patent, consists of 2-in tiles, reind with truss-metal, such as is used in the New York floor-arch. (See Fig. 28.)

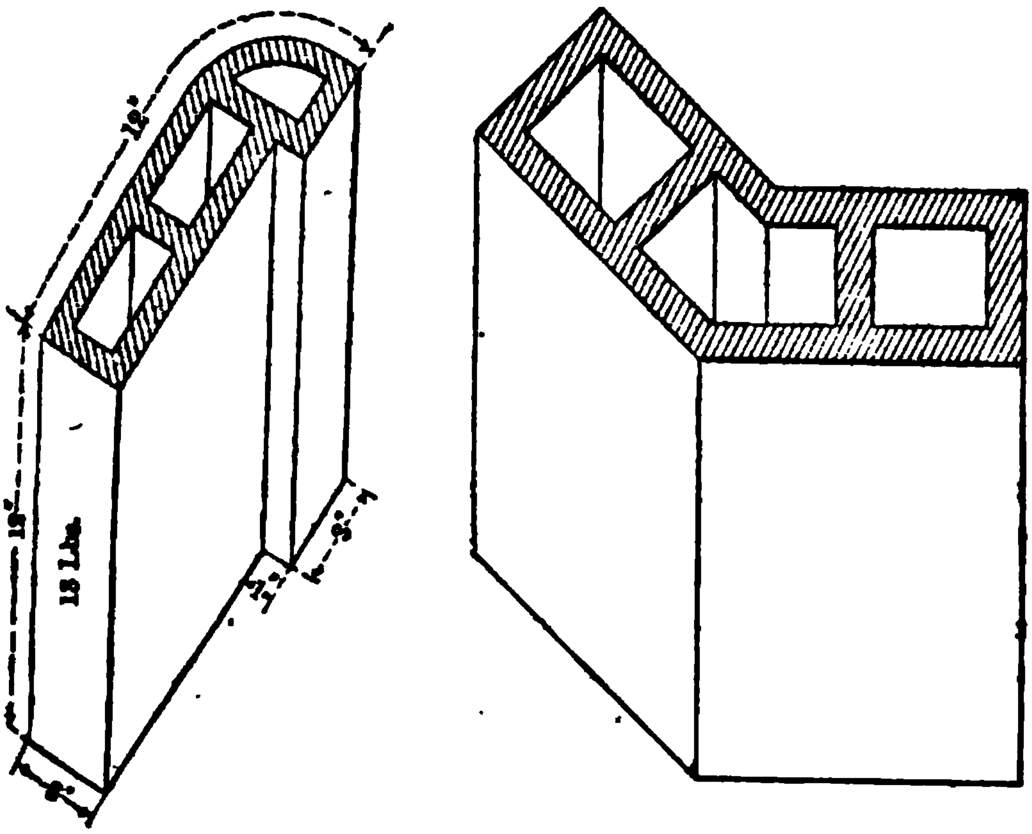

Fig. 61. Hollow-tile Round-corner and Angle Partition-blocks

rous Versus Dense Materials. For inside partitions the POROUS mate- are preferable to the DENSE, while for outside walls the dense materials d be used. With DENSE TILING it is necessary to insert either wooden g-strips, which are very objectionable, or blocks of porous tile to take place. It is becoming daily more difficult to get the sawdust necessary to the porous material.

rtar. Tile partition-blocks should be set in mortar made of one part utty, two parts cement, and from two to three parts sand. The blocks l be well wet before setting and the partition wet down before the plaster- applied.

ights and Lengths of Terra-Cotta Partitions. "The safe HEIGHT ra-cotta partitions in inches may be approximated by multiplying the ess in inches by 40. Common practice allows a safe height of 12 ft for 16 ft for 4-in, and 20 ft for 6-in partitions. For partitions without side- rts the LENGTH should not materially exceed the safe height. Doors and indows may be considered as side supports, provided the studs run from o ceiling."†

ights. The WEIGHTS of either POROUS or DENSE terra-cotta partitions not be taken at less than the following, adopted by the Hollow Building ssociation, as proper average weights:

2-in partition, 14 lb per sq ft;
3-in partition, 16 lb per sq ft;
4-in partition, 18 lb per sq ft;
5-in partition, 20 lb per sq ft;

* Made by Henry Maurer & Son, New York.
† Freitag.

6-in partition, 22 lb per sq ft for one-cell blocks;
6-in partition, 24 lb per sq ft for two-cell blocks;
8-in partition, 30 lb per sq ft;

not including plastering, which adds about 10 lb per sq ft for both sides.

Concrete Partitions. Partitions of stone concrete are seldom used beca of the forms necessary for their erection, which make them comparativ expensive. Unless reinforced they take up too much room. Furtherm they are the heaviest of all partitions. Even in buildings that are entirely reinforced concrete they are not always used. Cinder-concrete partitions somewhat lighter and considerably cheaper than those of stone concrete. even these are too heavy and too troublesome to construct to be satisfacto Among the partitions tested and approved by the New York City Build Bureau is one that consists of cinder-concrete blocks, 2½ and 3 in thick, thicker ones being hollow, 12 in high, and 18 in long. They have their ed cast with tongues and grooves that furnish more or less of a bond between blocks when they are set. Hollow, concrete building-blocks make fairly g partitions, but are objectionable on account of their thickness and weight.

Gypsum-Blocks. The term GYPSUM-BLOCKS is now more generally ployed than the term PLASTER-BLOCKS, as it is more accurately descriptive. principal makes on the ma are the ACME, made by Acme Cement Plaster C pany, St. Louis, Mo.; ANCHOR, made by the Am can Gypsum Company, Clinton, O.; the PYRO made by the United St Gypsum Company, Chic Ill.; the BELL, made by Rock Plaster Manufactu Company; the blocks of Niagara Gypsum Comp and the M. A. Reeb Corp tion, both of Buffalo, N. and the blocks of the Plym Gypsum Company, Dodge, Iowa. The usual of these blocks is 12 in in, although some are 13½ in by 32 in. The thickness is generally 2, 3, 4, 5, 6, and 8 in, for the low blocks, and 2 and 3 in for the solid blocks.

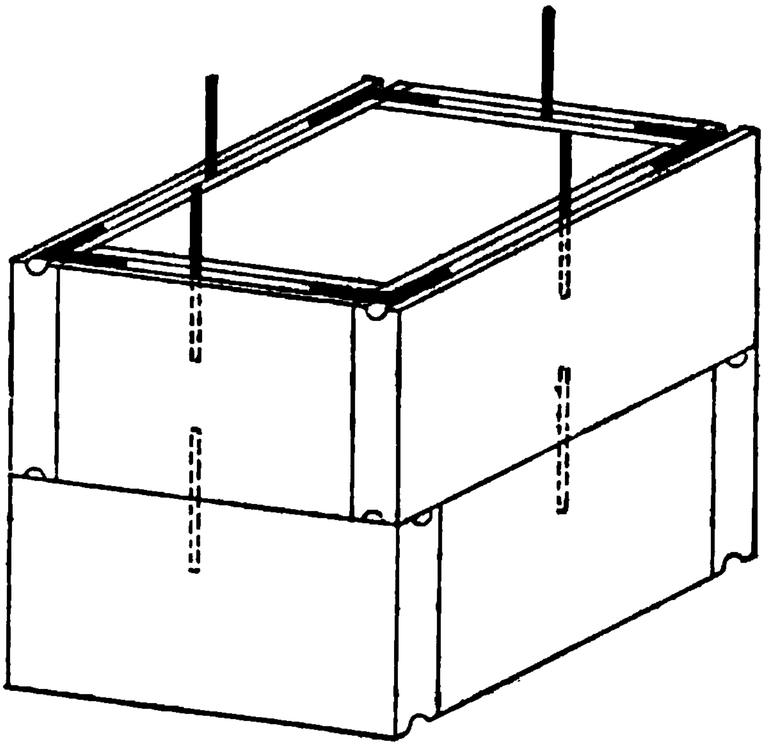

Fig. 62. Plaster-blocks. Doweled Construction.

Gypsum-Block Partitions. Blocks made of gypsum (plaster of P combined with various substances, such as cinders, wood chips, cocoanut asbestos, etc., have been largely used for partitions in fire-proof buildings. principal advantages claimed for these partitions are their great lightnes reduced cost compared with other forms of partitions. Gypsum blocks c readily cut with a saw, and have a considerable holding power for nails. fire tests, made for the Bureau of Buildings, New York City, they have gen shown considerable resistance to the flame and have transmitted less heat partitions of any other form. They did not, however, always stand the stream, some of them being easily pierced, and all of them being more o washed away by the water. An objectionable characteristic of these bloc

ir tendency to absorb moisture while being stored and to draw water from the stering when it is applied. This moisture works down to the bottom the partition where it is likely to injure the wooden base. These par-ns are made in THICKNESSES varying from 2 to 4 in, those less than 3 in hickness generally being solid; and their height should not exceed from 50 50 times the thickness of the blocks, unplastered. Hollow blocks should ays be set with the cells horizontal. The edges of the blocks are generally wed or otherwise arranged so that the mortar joint forms a key between n. In some forms of these partitions the blocks are BONDED together by as of metal dowels,* running across the horizontal and vertical joints from block into the adjoining one, as shown in Fig. 62. The cut illustrates the of the block in the construction of dumb-waiter shafts and shows how the ks are anchored at the corners by iron dowel-angles. Gypsum plaster is l in laying plaster-blocks, and occasionally fibered-gypsum plaster, tempered sand, may be employed. All of the partitions in the newer portions of the adnock Block, Chicago, and in many other prominent buildings of Chicago New York City, are of Gypsum blocks. Gypsum blocks make the lightest tical partition known. The weight of these partitions per square foot may aken as follows;

Thickness of block, inches . .	2	3	4	5	6	8
Weight in lb per sq ft	10	12½	14¼	17¼	19	26

out 8 lb per sq ft should be added to obtain the weight of the partition plastered on both sides.

ackolite. A plaster-block extensively used is the Mackolite Hollow Block, by the A. B. Fireproofing Company, Chicago, Ill. Mackolite partition tiles generally made in the form n in Fig. 63. The 3-in, 3½-in, -in tiles are made 48 and the s 30 in long, all the tiles being high. The blocks are laid in ir courses, breaking joint as t-stone work. Lime mortar ed for setting. In fitting d openings or at angles the are cut with a saw, and this a material saving in time aterial. It is claimed that ocks make very strong par-. The composition of the is plaster of Paris mixed ertain chemicals, reeds, and Reeds of the same length blocks are placed in the molds and the plaster of Paris and fiber are then with water, to which the chemical has been added, and poured around the o that they are nowhere exposed. The reeds give longitudinal strength to cks while the fiber makes them tough and elastic. The material sets in half an hour, after which the blocks are kiln-dried for four days.

FIG. 63. Mackolite Partition-blocks

sinite Partitions. The main feature of these partitions is the GYPSINITE hich is handled and erected in the same manner as a wooden stud in the y non-fire-proof partitions. The stud is composed of wooden nailing- ompletely protected and embedded in a plaster-composition known as

nted by the Sanitary Fireproofing and Contracting Co., New York City.

GYPSINITE CONCRETE. The studs are carefully made and are plumb and t
Metal lath or plaster-boards are secured to the studs and plastered, complet
the partition, which is about 4½ in thick. (Fig. 64.) This partition is sligh
heavier than the ordinary partition of wooden construction. It is q
as stiff and as strong as a good tile or other partition, and the nailing-s
feature of the studding facilitates the application of a wooden trim.
is said to be particularly sound-proof, and the spaces between the st
afford an opportunity to conceal pipes, wires, etc. Gypsinite studs are 3 b
by 12 in, and weigh 3 lb to the foot. They can be made any size requi

Fig. 64. Gypsinite Studs, Metal Lath, and Plaster

In the partitions the studs are usually placed 16 in on centers and bridged
may be required They are fastened to the floor or ceiling by the use of s
and plates of the same material, or by light channel-irons, which are spiked
the fireproofing. The manufacturers believe that in large quantities these st
can be furnished as cheaply as wooden studs and that the partitions can
erected as cheaply as ordinary lath-and-plaster partitions. Gypsinite studs
manufactured by the United States Gypsum Company, Chicago, Ill.

Solid, Plaster-and-Metal Partitions. Thin partitions of plaster appl
to metal lath and metal studs, made solid, and finished about 2 in thick, h
been extensively used in fire-proof buildings. They are remarkably stiff, ow
to the adhesion of the plaster to the steel, and they are lighter and occupy
space than any other practical fire-proof partition of equal strength. In
fire tests these partitions act very much like the plaster-block partitions, re
ing thoroughly the passage of the flames. But the plaster always washes
when the hose is applied and the lath becomes exposed. The rigidity of

al fabric on the metal studding has been considered by firemen a disadvantage, as it is very difficult to cut through it when necessary to get at a fire. construction of these partitions is practically the same for the different ics used, which are described on pages 846 to 850. This lath or fabric aps to be subject to the CORROSIVE EFFECTS of the plaster. In the demolition e Pabst Building, New York City, the metal lath used throughout in the itions was found to be considerably corroded, after about four years, even gh the lath had been painted. On the other hand other cases are cited by

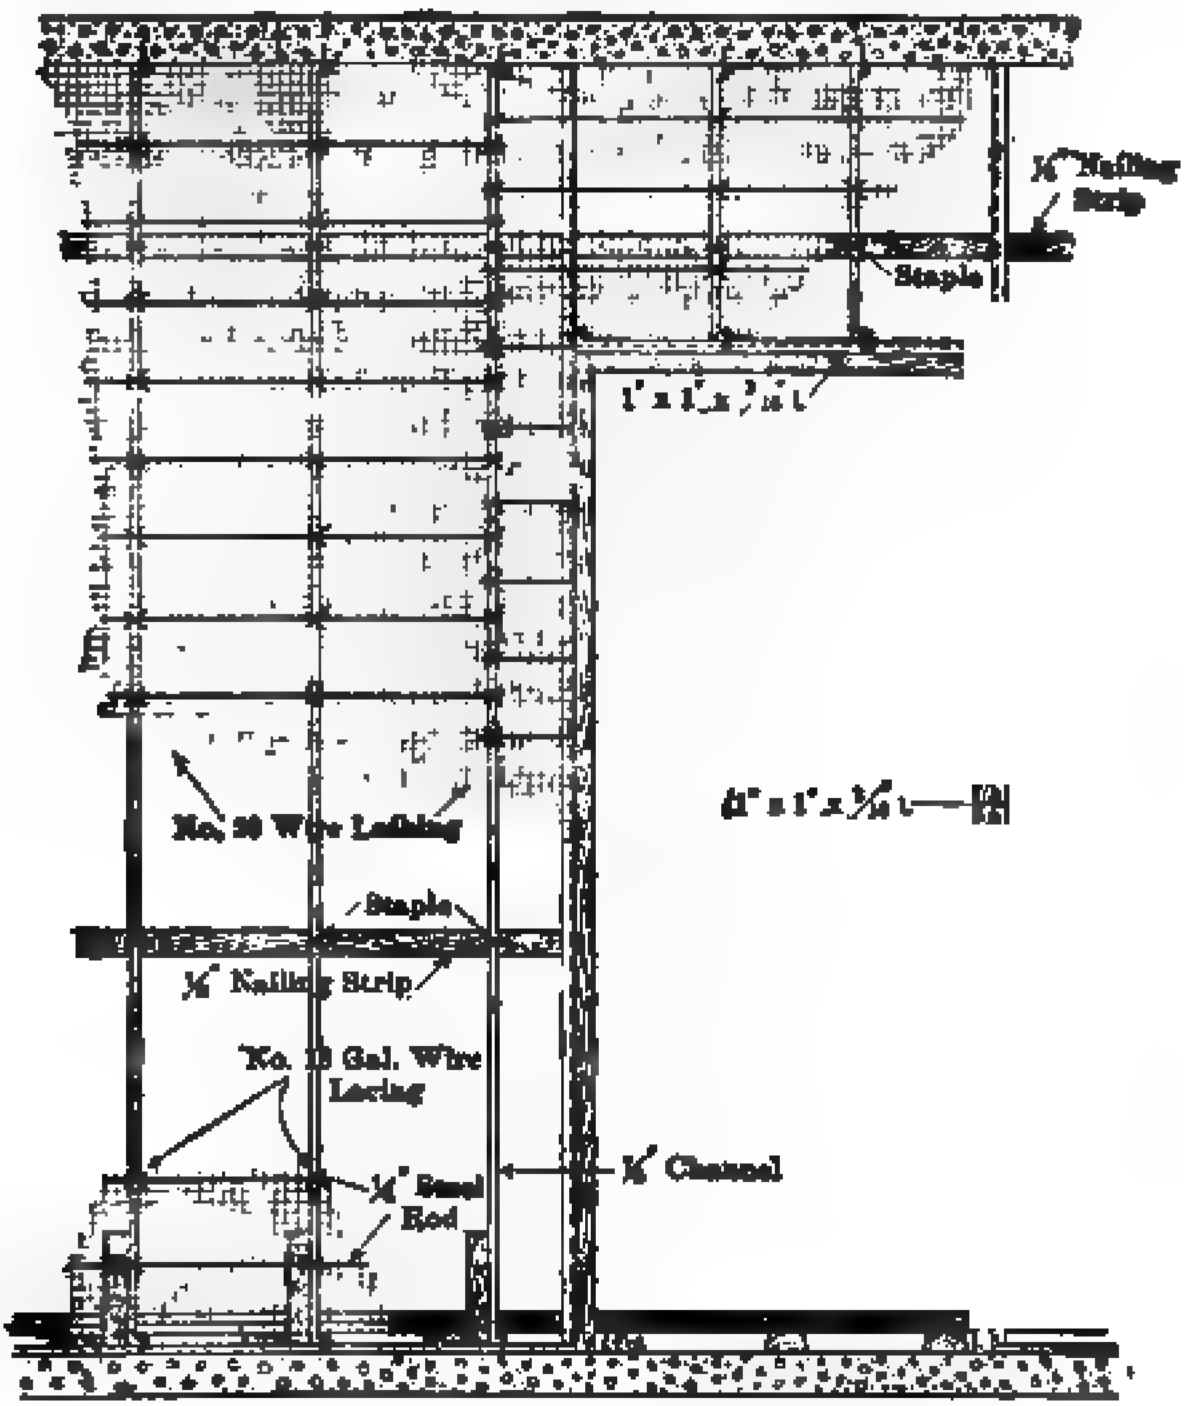

Fig. 66. Two-inch Solid Plaster Partition. Elevation

anufacturers, such as the Chess residence at Pittsburgh, Pa., the Sturtevant nce at Springfield, Mass., and the West End Trust Building at Philadelphia, in which after twenty years no corrosion of the metal lath in plaster parns was observed. The investigations of the United States Bureau of ards of various forms of stucco-construction seem to bear out the manurers' contention. The lath should in all cases be protected against initial ipient corrosion by painting or galvanizing before being embedded in the ntitious material.

ights of Plaster-and-Metal Partitions. The WEIGHT of a 2-in solid ion, when dry, is about 20 lb per sq ft. The weight of partitions of greater

thickness may be estimated on a basis of 120 lb per cu ft for plaster, and for cinder concrete, slightly tamped.

Construction of Solid Two-Inch Partitions. Figs. 65 and 66 show usual method of constructing 2-in partitions. The studs, usually ¾-in o

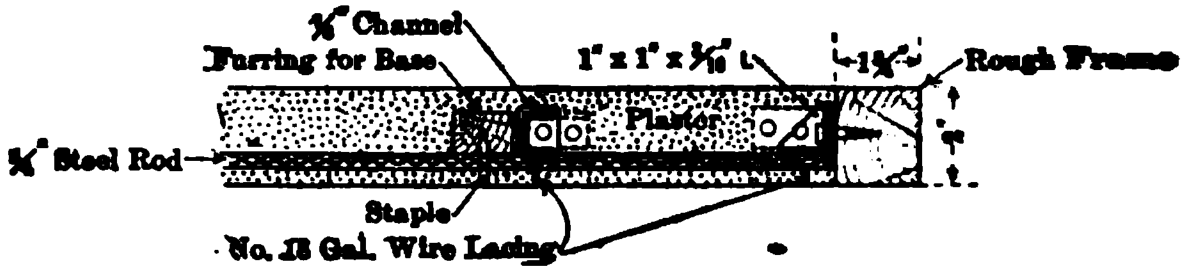

FIG. 66. Two-inch Solid Plaster Partition. Horizontal Section

channels, are bent and punched at the ends, and at the bottom are nail wooden strips, which are first secured to the floor-panels, or to the top steel beams where the partitions come over them. These wooden strips been found necessary as a sort of cushion to allow the studding to expa case of fire. At the top, the studs are nailed to the underside of the floor-p or, if there is a suspended ceiling, they are wired to the bars supportin ceiling. At the openings, 1 by 1 by 3⁄16-in angles are used, and these are every 16 in for No. 12 screws, used in attaching the rough wooden fram the angles. After the studding is in position, the metal lathing is laced t side of it with No. 18 galvanized wire. After the lathing is in place th penter should attach wooden grounds to secure the base, and pegs or spot-gr for chair-rail, picture-molding, etc. These grounds are secured by st and when the partition is plastered, become very rigid. In plastering partitions, five coats of plaster are required to make a good job; a scratcl on one side, a brown coat on each side, and the usual white coat on each si finishing. It is essential for all thin partitions that a HARD-SETTING mort used, such as Acme Cement, King's Windsor Cement, Adamant, or Rock Plaster.* The partitions acquire their STIFFNESS largely from the solidity plastering, hence the firmer and harder the plastering the more substanti walls.

Double Partitions. Electric wires and ½-in gas-pipes can be run in th SOLID PARTITIONS; but if it is desired to run larger pipes, DOUBLE PARTI

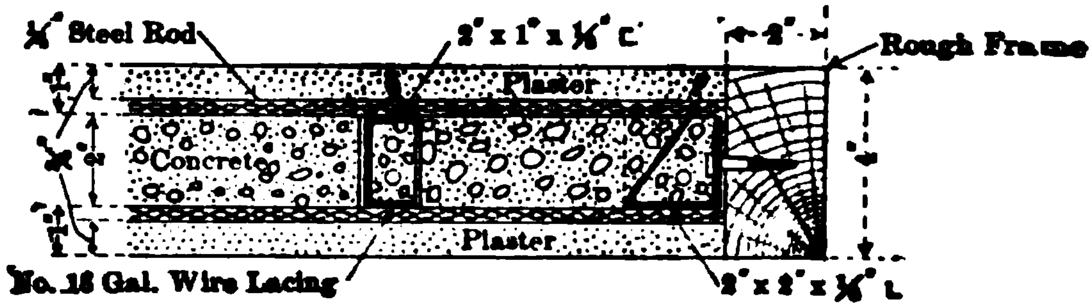

FIG. 67. Four-inch Solid Plaster and Concrete Partition. Horizontal Secti

that is, partitions with lathing on each side of the studding, must be used these partitions, 2-in, 3-in, or 4-in channels, or flat bars set edgewise, may b sheet-steel channels being probably the most economical. When the between the studs is not filled with mortar or concrete, the DOUBLE PAR

at stand fire and water as well as the SOLID PARTITION, while it is much more sive.

astruction of Solid Four-Inch Partitions. Fig. 67 shows a partial sec- hrough a SOLID PARTITION finishing 4 in thick when plastered. It has great gth and resistance to fire and water, and affords nient spaces for pipes and thicker jambs for frames. These partitions have cores of cinder ete, with metal lath on both sides, and are plas- in the usual way. As the concrete will receive no wooden furring is required to fasten the base- s, chair-rails, and picture-moldings in place.

rger's Economy Studding and Furring. Fig. lustrates a patent stud manufactured by the r Manufacturing Company, Canton, Ohio. It de of No. 18 or No. 20 sheet steel, and in five varying from ¾ to 1¼ in. The peculiar ad- ge of this stud is the provision for attaching the For this purpose prongs are punched from sides of the flange, which are left standing at angles to the face of the flange. The lath is l against the stud, the prongs pressed through eshes and then turned up over the lath with a er. This fastens the lath more firmly and ly than by any other method. The ends of the are secured by sockets which are fastened to the and ceiling, a clear space being left above the f the studs for expansion. Where partitions ect or where there are angles, angle-irons with s are used in place of the T irons. By using studs and expanded-metal lathing, a saving in an be effected over the construction shown in 6. These T's are used, also, for supporting nded ceilings under I beams, the T's being d to the flanges of the beams by specially de- clips. Furring-strips and channels, also, are on the same principle.

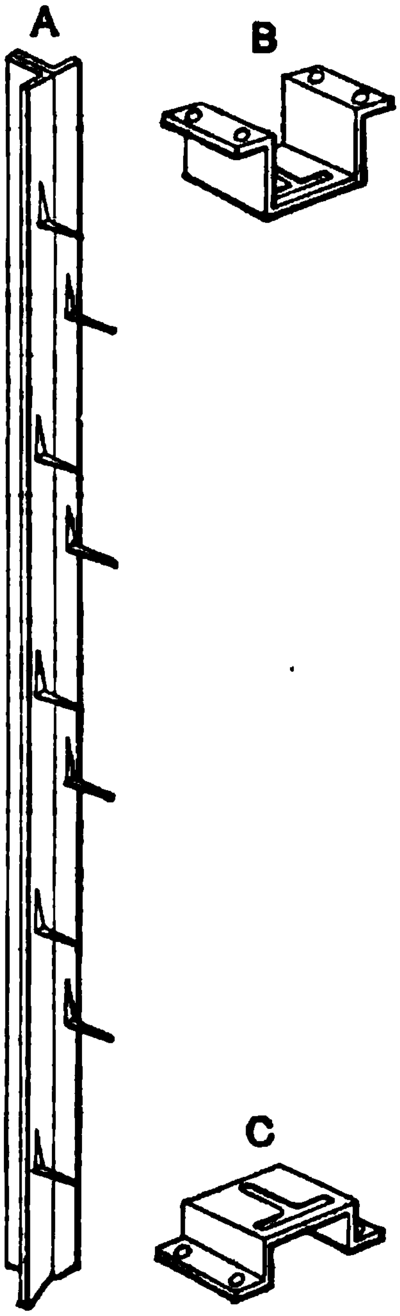

FIG. 68. Berger Studding or Furring and Stud-sockets

cing of Studs in Two-Inch Solid Partitions. in solid partitions with ¾-in rolled channels or conomy Studs, the studs should be placed 12 enters when the height of the story exceeds 10 ft. When the height of ry is less than 10 ft, a spacing of 16 in will answer. For hollow partitions -in studs, the studs can be spaced 16 in on centers for story-heights of 61 less. For greater heights they should be placed 12 in on centers.

Stud. In Fig. 69 is shown the Rib Stud made by the Truscon Steel ny, Youngstown, Ohio. It is made in widths of 2¼, 3¼, 4¼, 6¼, and and in lengths up to 18 ft. The studs are made of OPEN-HEARTH STEEL, o-rib studs weighing 0.55 lb per ft and the three-rib studs, 0.85 lb per ft. n SOLID PARTITIONS with ¾ or 1-in channels or studs, the studs should ed from 12 to 16 in on centers, depending upon the stiffness and rigidity ath. A 12-in spacing should never be exceeded when the height of story than 12 ft. For HOLLOW PARTITIONS with 2-in studs, the studs can ed 16 in on centers for story-heights of 16 ft or less, when No. 24 (United gauge) expanded metal or No. 18 (United States gauge) wire lath, 2½ by

2¼ mesh, are employed. For greater heights the spacing should never ex
12 in. No. 22 (United States gauge) expanded metal, weighing at least 4
per yard, and No. 20-gauge V-stiffened wire lath or wire lath with rods or
eners spaced 7¼ to 8 in on centers, give satisfactory rigidity for both parti

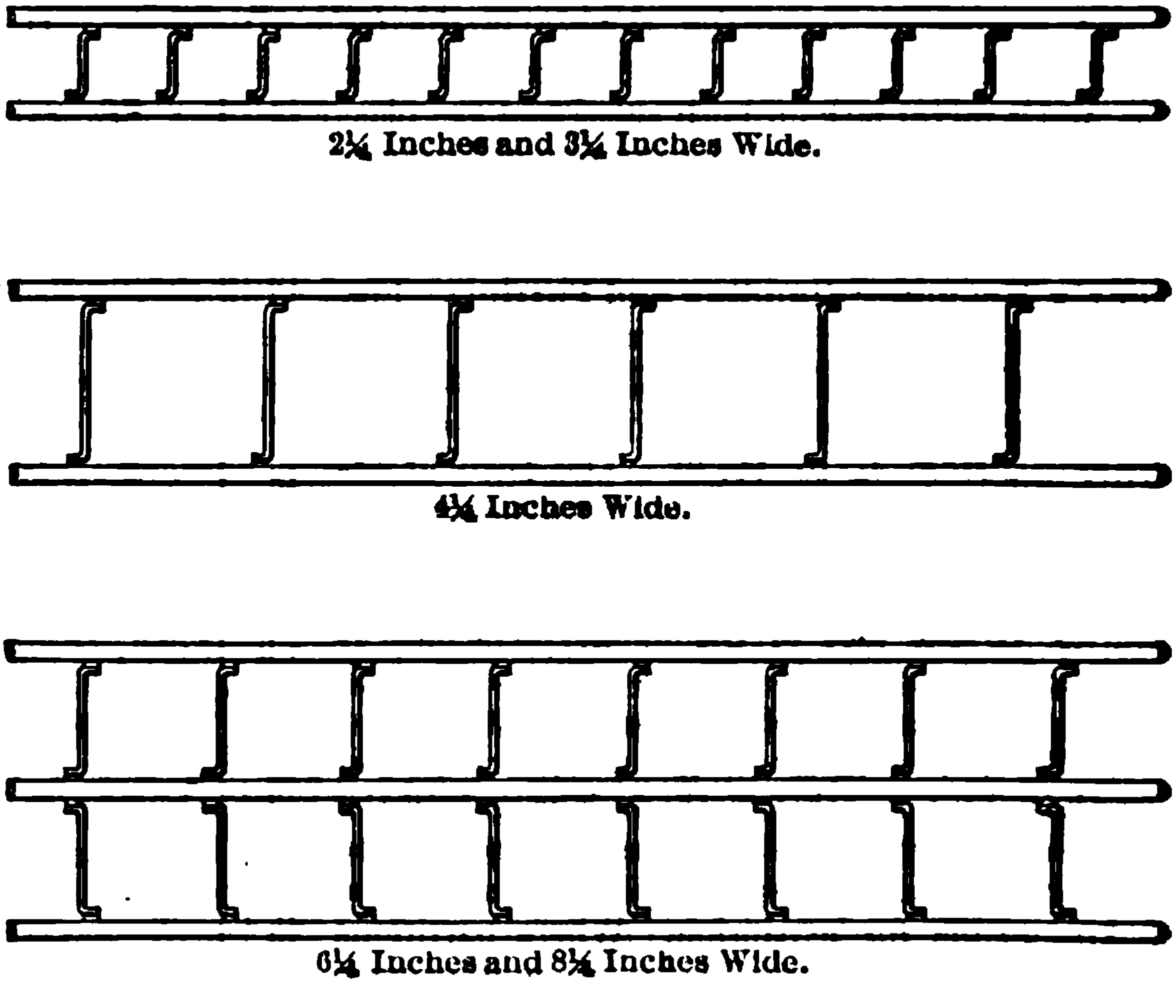

FIG. 69. Rib Stud for Plaster Partitions

and ceilings when the studs or furring-strips are set 16 in on centers. I
should be wired to the metal studding with No. 18-gauge annealed galvan
wire.

Metal Lath. Numerous styles of METAL LATH have been put on the ma
in recent years to provide for a cheap, light, and thin partition-construct

lime or cement. Where a
ticular type of lath is

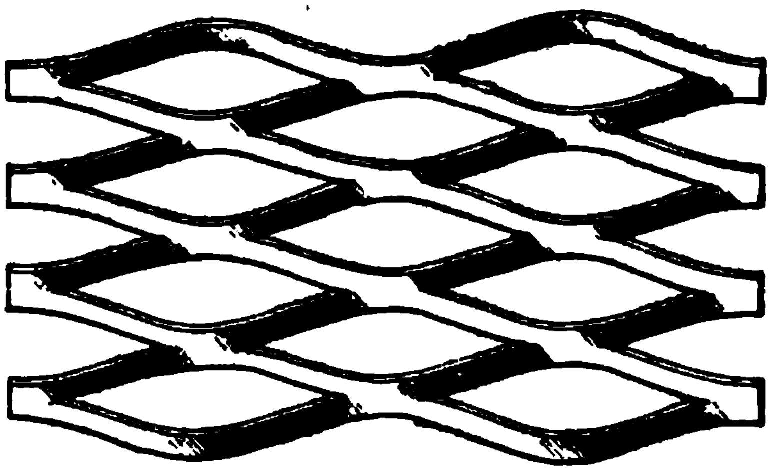

FIG. 70. Expanded-metal Lath with Diamond-shaped Mesh

mentioned in a specification, it should be generally described as foll
"Painted or galvanized No. 24-gauge expanded-metal lath, weighing not
than 3½ lb per sq yd, or painted or galvanized woven-wire cloth, No

ge, 2½ meshes to the inch, with stiffeners placed 8 in on centers and weigh- not less than 3⅓ lb per sq yd." Metal lath should be so made that it will plaster freely, key it thoroughly, and wholly embed itself in it. These are acteristics of expanded-metal and woven-wire laths which make them rior to sheet lath. Sheet laths are economical in the use of mortar, which ly covers one side of the lath and latches through the perforations without oughly embedding the metal. The difficulty of stretching plain wire lath enough to make a firm foundation for plaster and the resulting necessity close spacing of the studs to secure the required bearing, has led to the duction of stiffened wire cloth and ribbed or corrugated expanded metal der to obtain the necessary rigidity. To overcome the necessity for separate ing-studs, expanded-metal and sheet-metal laths are manufactured also in a piece steel lath-and-stud.

PANDED METALS differ in the process of manufacture. One type is made mply slitting the sheet and deploying it into the diamond shape; the other is made from thin s of soft, tough by a mechanical ss which pushes and expands the l into the mesh at the same time ses the direction e edge, so that the urface of the cut d is nearly at angles to the al surface of the . It is claimed the COLD WORK- of this low-carbon steel increases the ELASTIC LIMIT and ULTIMATE NGTH. In specifying expanded metal, it is necessary to give the weight of nished product per square yard as well as the gauge of metal, as the strands be of various widths. EXPANDED METAL is made either with diamond-shaped 70) or rectangular (Fig. 71) meshes. When laid with the long strands per- icular to the studs, the lath with the rectangular mesh is the stronger of the Rigidity is also obtained by corrugating and expanding the metal in various , which make the so-called ribbed, corrugated, and integral laths. WIRE l is stiffened by clipping corrugated-steel furring-strips to the lath or by ing or welding rods or V-shaped stiffeners at regular intervals.

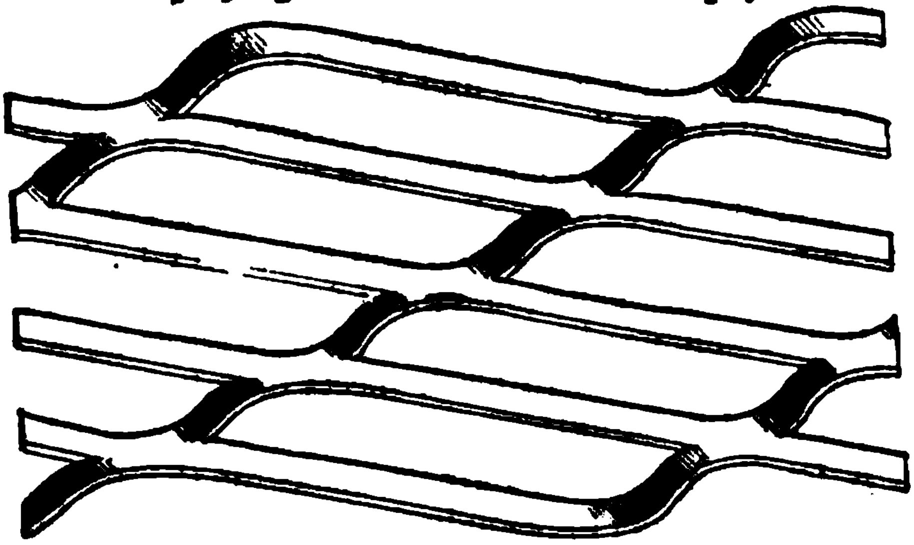

FIG. 71. Expanded-metal Lath with Rectangular Mesh

pes of Metal Lath. Metal lath may be classified as follows:

Expanded-metal lath;
- (a) Diamond and rectangular mesh,
- (b) Ribbed or corrugated,
- (c) Integral, combining functions of both lath and studding,

Sheet lath;
- (a) Flat perforated,
- (b) Integral, combining functions of both lath and studding,

Woven-wire lath;
- (a) Plain,
- (b) Stiffened.

e of the laths and their characteristics are given in the following para- s.

(1) Expanded-Metal Lath

Rotary Diamond-Mesh Lath. This lath is made by the Berger M facturing Company, Canton, Ohio. It is furnished in sheets 18 by 96 i Nos. 27, 26, 25, and 24 gauge, weighing respectively 2⅓ lb, 2½ lb, 3 lb, an lb per sq yd. It is made of Toncan Metal, for which greater HOMOGENEI claimed than for charcoal-iron and steel, and less liability to CORROSIO PITTING.

Bostwick Lath. Bostwick lath is made by the Bostwick Steel Lath C pany, Niles, Ohio. It is furnished in sheets 14 by 96 in, approximately 1 sq and also 24 by 26, and is made in Nos. 24 and 27 gauge.

Steelcrete Lath. This material is manufactured by the Consolid Expanded Metal Companies, Braddock, Pa., and is furnished in two st known as STEELCRETE A lath and STEELCRETE B lath, for exterior stucco-w and in the standard-form DIAMOND LATH, extensively used for exterior an terior plastering-work. STEELCRETE DIAMOND LATH is divided into three d nations, P LATH, F LATH, and H LATH. The P LATH meets the specificatio the United States Post Office Department, weighs 4.37 lb per sq yd, and is m factured from 22-gauge material in sheets 24 by 97 in. The F LATH is manu tured in sheets 24 by 97 in from the gauges 24, 25, 26, and 27, respecti weighing 3.40, 3.00, 2.55, and 2.33 lb per sq yd. The H LATH has a size of s 28 by 97 in and is manufactured from the gauges 24 and 26, weighing resp ively 2.90 and 2.20 lb per sq yd. STEELCRETE LATH can be obtained manu tured from open-hearth black sheets or galvanized sheets, or in copper-bea sheets (acid-resisting).

A Diamond-Mesh Lath is made by the Penn Metal Company, Bo Mass., in sheets 24 by 96 in in size and of the following gauges: No. 22, weig 4 lb per sq yd; No. 24, weighing 3.4 and 3 lb per sq yd; No. 26, weighing 2 per sq yd; and No. 27, weighing 2.3 lb per sq yd. For such extraordi conditions as are found in gas-plants, dye-works or places where exces moisture or salt-air action exists, Hampton Rust-Resisting Lath is made.

Key Expanded-Metal Lath, made by the General Fireproofing Comp Youngstown, Ohio, is furnished in sheets 24 by 96 in, in Nos. 27, 26, 25, an gauge, weighing respectively 2.34, 2.50, 3.00, and 3.40 lb per sq yd.

Kno-Burn Lath, made by the North Western Expanded Metal Comp Chicago, Ill., is furnished in sheets 18 by 96 in, in Nos. 27, 26, 25, and 24 ga weighing respectively 2⅓, 2½, 3, and 3.4 lb per sq yd. When made fro special ACID-RESISTING sheet steel, this lath is sold under the name XX Cen Expanded Metal Lath.

Herringbone Expanded Metal Lath (Fig. 72), made by The General proofing Company, Youngstown, Ohio, is furnished in three styles, A, AAA, BB. STYLE A is made in sheets 13½ by 96 in (1 sq yd), of No. 28-gauge m weighing 3 lb per sq yd. STYLE AAA is made in sheets 18 by 96 in, and from 26, and 24-gauge metal, weighing 2.53, 2.81, and 3.79 lb per yd, respectiv STYLE BB is made in sheets 20¼ by 96 in (1½ sq yd), of Nos. 27, 26, and 24-g metal, weighing respectively 2¼, 2½, and 3¾ lb per sq yd. It is made of s American ingot-iron, or galvanized sheets. Ribs are set across studs and d down towards them.

Sykes Expanded Cup-Lath, made by the Sykes Metal Lath and Roo Company, Niles, Ohio, is furnished in sheets 18 by 96 in, with an anti coating, or painted black, or galvanized. It is made of Nos. 27, 26, and gauge metal, weighing respectively 2.8, 3, and 3.7 lb per sq yd.

andard Rib Lath, made by the Truscon Steel Company, Detroit, Mich., rnished in sheets 20¼ by 96 in, in grades 1, 2, and 3, weighing respectively ,3.42, and 4.10 lb per sq yd. This company makes also the BEADED PLATE

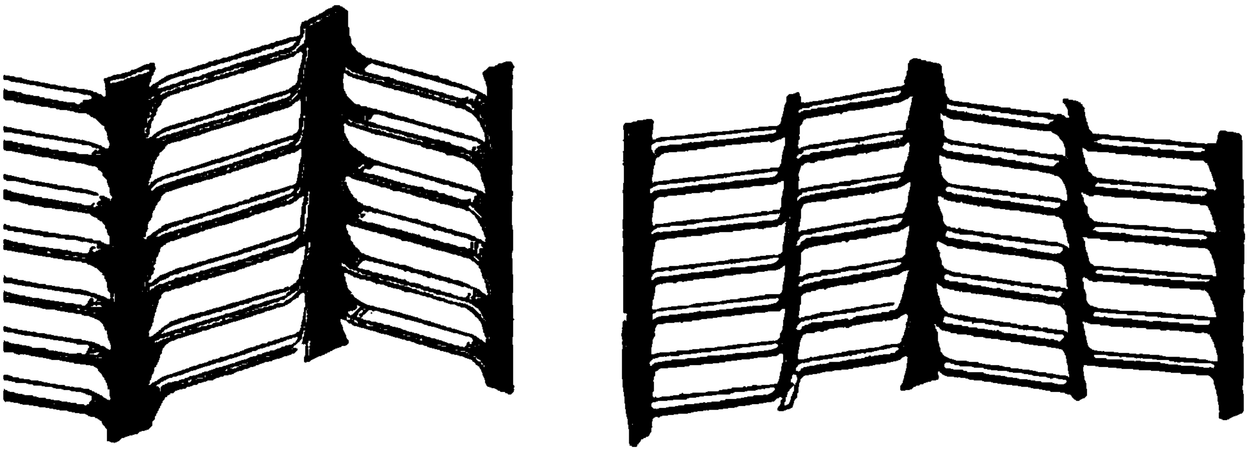

FIG. 72. Expanded-metal Lath, Herringbone Mesh

ATH, which is about 35% heavier and more rigid, permitting wider spacing : studs.

tmesh Diamond Expanded-Metal Lath is manufactured by the Mil-e Corrugating Company, Milwaukee, Wis. This lath is furnished in , 24 by 96; in 27, 26, 25, and 24 gauges, painted; and in 26 and 24 gauges hot-galvanized after cutting. This Company, also, makes CORRUGATED LF-FURRING LATH, in sheets 21½ by 96 in, same gauges, except No. 25, as TMESH.

o-Fur Lath, made by the North Western Expanded Metal Company, go, Ill., is furnished in sheets 22 by 96 in, of Nos. 24, 25, 26, and 27-gauge , weighing respectively 3.80, 3.36, 2.82, and 2.62 lb per sq yd. This lath ls running obliquely across the sheets at the same angle as the strands mesh. This corrugation is said to give the lath greater RIGIDITY so that be used on 32-in centers for walls and on 24-in centers for ceilings. The ations act as furring-strips. It is made from a special ACID-RESISTING and is always supplied painted.

egral Expanded-Metal Lath. Truss-metal lath, Fig. 73, made by the can Rolling Mill Company, Middletown, Ohio, is furnished in sheets

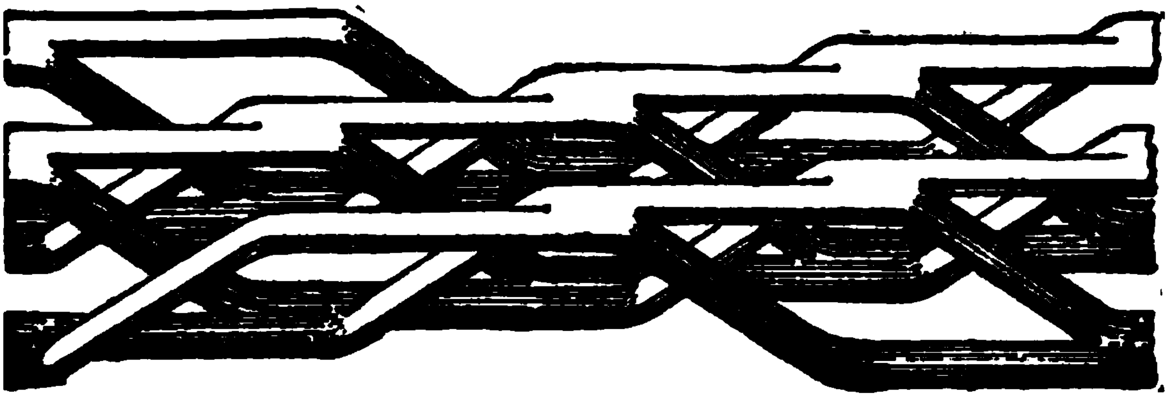

FIG. 73. Truss Metal Lath

)0 in, of Nos. 26 and 28-gauge metal, weighing respectively 80 and 66.7 lb) sq ft. A partition constructed of this lath in one of the test-structures mbia University, New York City, passed through and withstood, with-y sign of distress, the fire and hose-streams of five successive tests.

-Sentering, made by the General Fireproofing Company, Youngstown, s furnished in sheets 29 in wide and in lengths varying by 1 ft, from 4 to

12 ft, of Nos. 28, 26, and 24-gauge metal, weighing respectively 0.58, 0.70, 0.93 lb per sq ft. The width of 29 in is the covering capacity, as laps are vided for by outside ribs. (See, also, page 853.)

Hy-Rib, made by the Truscon Steel Company, Detroit, Mich., is furnish three types known as 4-Rib, 3-Rib, and Deep Rib. The first is in sheets in wide, and the others in sheets 14 in wide. (See, also, page 853.) All style furnished in Nos. 24, 26, and 28-gauge metal. The standard lengths are 6, and 12 ft. Other lengths below 12 ft are cut, but the waste is at the cost o purchaser. Hy-Rib sheets interlock at the sides and ends. In ordering allowance need be made for side laps, but for end-laps 2 in should be allowe laps over supports, or 8 in between supports.

Trussit is manufactured by The General Fireproofing Company, You town, Ohio, in sheets 19 in in width, and in lengths of 8, 10, and 12 ft, from 26, and 24 gauge, weighing 0.57, 0.62, and 0.83 lb per sq ft, respectively.

(2) Sheet Lath

Clinched Lath, made by the American Rolling Mill Company, Mi town, Ohio, is furnished in sheets 13½ by 96 in (1 sq yd), of No. 30-gauge m weighing 4½ lb per sq yd.

Truss-Loop Lath, Fig. 74, made by the Bostwick Steel Lath Comp Niles, Ohio, is furnished in sheets 13½ by 96, 16¾ by 80, 24 by 96, and 2 96 in, weighing 4½ lb per sq This lath is furnished painted u otherwise specified.

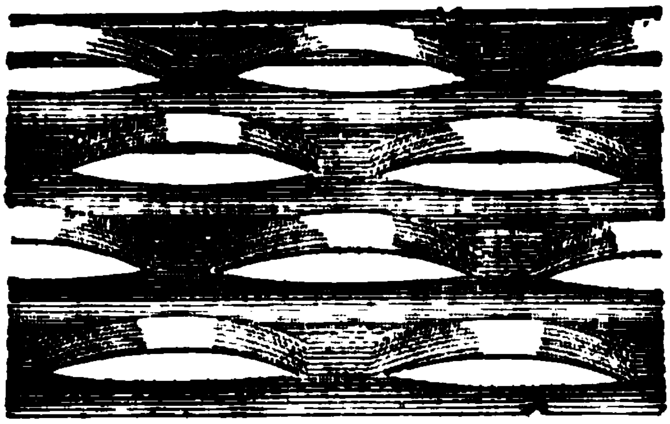

Fig. 74. Bostwick Truss-loop Lath

Genfire Sheet-Steel L made by the General Fireproo Company, Youngstown, Ohio, furnished in sheets 24 by 96 weighing 4.6 lb per sq yd, pai unless otherwise specified.

Sykes Trough Sheet L made by the Sykes Metal L and Roofing Company, Niles, O is furnished in sheets 13½ by 9 (1 sq yd), 15½ by 96, 18½ by 96, and 23¾ by 96 in, weighing 5 lb per sq and made with an antirust coating, or painted or galvanized.

Integral Sheet Lath. Rib-Truss, made by the Berger Manufactu Company, Canton, Ohio, is furnished in widths of 24 in, and in stock length 4, 5, 6, 8, 10, and 12 ft, as follows:

Gauge	Weight per square yard in pounds		
	1½-in rib	¾-in rib	1-in rib
27	73	78	83
28	81	86	92
26	88	94	100
24	117	125	133

(3) Woven-Wire Lath

Woven-Wire Lath is furnished with or without STIFFENERS, which are either h or V-SHAPED RIBS running through the wire mesh to reinforce and stiffen it. is supplied painted or unpainted, or it is galvanized after weaving. It can be nished to order in any required width up to 10 ft. In widths less than 18 in, re is a small charge for STRIPPING. Before ordering, it is very important to ertain the proper width, especially of stiffened lath, as it is desirable to have edges of the lath lap at the supports where it is laced to iron furring. When lath is not of the proper width the results are not so good and there is liable e a waste of material. The standard width of PLAIN and of V-RIB STIFFENED h is 36 in. When beams or studs are spaced 16 in from center to center, the h should be 32 or 48 in wide.

The Clinton Stiffened Lath has corrugated-steel FURRING-STRIPS attached ry 8 in, crosswise of the fabric, by means of METAL CLIPS. These strips con- ute the FURRING, and the lath is applied directly to the underside of the floor- ts, or to planking, furring, brick walls, etc. This lath is made in 36-in widths, h 2½ meshes to the inch, and comes in 100-ft rolls. The manufacturers of lath make, also, a lath STIFFENED WITH ROUND RODS, ⅛ to 1 in in diameter, ced from 8 to 12 in apart. It can be had either galvanized or japanned, and hicknesses from 18 to 21 gauge. Clinton plain WIRE LATH is furnished in rolls ft long.

The Roebling Standard Wire Lath (controlled by the New Jersey Wire th Company, New York), is made of plain WIRE CLOTH, in which, at intervals ½ in, STIFFENING RIBS are woven. These have a V-shaped section and are made of 24 sheet steel, ⅜ and 1 in in depth The n rib is the standard size for lathing on dwork. This lathing requires no furring, is applied directly to woodwork or to s with steel nails driven through the bot- of the V, as shown in Fig. 75. The No. V-rib stiffened lathing affords a satisfac- surface for plastering, when attached to s or beams spaced 16 in apart. The 1-in b lathing is used for furring exterior s. It provides an air-space between the and plaster. Where this lath is to be ied to light iron furring, a 3/16 or ¼-in steel rod is substituted for the V-rib, the lathing is attached to light iron ng with lacing wire. This lath is distinguished from the others by the term -Rib Stiffened Wire Lath. The Roebling lath, whether plain or stiffened, de with 2 by 2, 2½ by 2½, and 2½ by 4-in mesh, the last named being n as CLOSE WARP. The 2½ by 2½ mesh is adapted to all plasters contain- he usual proportion of hair or fiber. The 2½ by 4-in mesh should be used ard plasters and thin partitions. The lath can be furnished in widths up to the rolls averaging 50 yd in length.

FIG. 75. Roebling V-rib Stiffened Wire Lath

all-Boards. There are various forms of WALL-BOARDS of an incombustible e, most of them made of gypsum in combination with felts. They can be as substitutes for laths. They are very light and require but little plaster- aterial. When this saving is taken into account, wall boards cost less than lath and but little more than wooden lath with three coats of plaster. The

boards are generally 32 by 36 in in size, and 1/4, 5/16, 3/8, or 1/2 in in thick
The thinnest boards (1/4 in) weigh 1 1/2 lb per sq ft, and the thickest (1/2 in) 2
Wall-boards of asbestos are described on page 819. The best known is TRAN made by the H. W. Johns-Manville Company, New York.

Sackett's Wall-Board. This is a composite board of three layers of gypsum and four thin layers of wool-felt. The boards can be nailed to woo studding or set flat against solid beams or planks, and can be cut with a s For plastering, the best results are obtained by applying first a brown coa hard wall-plaster, 1/4 to 3/8 in thick, and when this is thoroughly set, finishi with a thin coat of regular hard finish of lime-putty and plaster. Tests investigations at the Underwriters' Laboratories "have shown Sackett Bo Perfection Brand, to be suitable as a base for fibered-gypsum plasters; and w attached to walls, ceilings, and partitions and coated with 1/2 in of plaster, pos fire-retarding properties considerably higher than those of wooden lath w gypsum or lime-and-cement plaster." The Perfection Brand, Sackett's W Board, is 3/8 in thick, and is attached with No. 10 1/2, 1/4-in, flat-headed, 3/4-bar wire nails, 1 1/4 in long, and spaced not more than 6 in at each support. SACKE BOARD is made by the United States Gypsum Company, Chicago, Ill., and Grand Rapids Plaster Company, Grand Rapids, Mich. Other makers of gyp wall-boards are the J. B. King Company, New York (Diamond Brand), Southern Gypsum Company, North Holston, Va. (Economy Brand), and American Gypsum Company, Port Clinton, Ohio (Monarch Brand).

Metal-Rib Plaster-Board is composed of alternate layers of strong absorb paper reinforced with fine annealed wire about 2 in on centers, and stiffe transversely with 1/2-in iron bands, No. 32 gauge, placed 8 in on centers. material is made up to a total thickness of about 3/16 in, impregnated wit coal-tar product, and provided every 2 in with 3/16-in circular holes to key plaster. This is added to the adhesive effect of the absorbent paper. I furnished in rolls 85 ft long and 34 in wide, nailed directly to the studs or be set 12 or 16 in on centers, and lapped 2 in at all joints. This board is rec mended for use with hard-plaster mortars only, and forms a satisfactory b for three-coat work, in which the lap-joint obviates the cracking frequen associated with ordinary plaster-board construction.

Bestwall. BESTWALL is primarily intended for use as an interior finish side walls and ceilings in buildings of all classes. It may be used in all situati where finishes of lath and plaster may be used, and in many situations w the latter finish is not adaptable. It consists of a single layer of fiber calci gypsum, surfaced on each side with specially prepared water-proofed paper curely bonded to the surface. Bestwall is 3/8 in in thickness, and is furnishe stock sizes 47 1/4 in wide, and in lengths of 5, 6, 7, 8, 9, and 10 ft. The finis product presents a smooth, true surface, which is light cream in color on face-side and gray on the reverse side. The edges are slightly beveled to vide for the filling of the joints, and are doubly reinforced. Its weight is proximately 1 850 lb per 1,000 sq ft. Interior finish composed of Bestwa applied by nailing the Bestwall directly to the joists, studs, and furring, filling the joints between the pieces of Bestwall with a specially prepared of the same composition as the core of the board. For the nailing, threepe fine wire nails, spaced from 2 to 3 in at the edges and from 8 to 12 in at the in mediate supports, are used. The filling consists of two operations; first, ROU ING IN and then, TROWELING OUT, to a smooth, true finish, flush with the surf Bestwall is cut and fitted either with a saw or by scoring and breaking ov straight-edge. The completed finish presents a smooth, true, continuous surf

thout showing joints or nail-heads, and ready to receive, if desired, a decoration paint, paper, tint, etc.

Shaft-Construction. The most important partitions in a building are those losing interior shafts. Vertical openings through buildings form flues and me up-drafts. In all buildings, fire-proof as well as non-fire-proof, therefore, y should be inclosed for two reasons: first, to prevent a fire that would find atural outlet in such openings from spreading to other floors; and secondly, prevent, as far as possible, a fire from getting into these openings where the ft would greatly increase its fury. To be thoroughly effective the inclosed ls should be constructed of the same materials as the outside walls of the ldings, namely, brick, stone, or concrete. While they need not be of the ne thickness as the outside walls, 12 in is recommended as a minimum thick-s. In less important structures terra-cotta partitions are sometimes used such inclosing walls. In the walls inclosing elevator-shafts no openings ept those necessary for entrance-doors should be permitted. The doors uld be of fire-proof construction, pages 901–2, and made solid. Glass lights sometimes provided in such doors, although this is not good practice; if y are used, wire-glass, only, should be used, in accordance with the limita-s noted on pages 902–3. Open grille-work for passenger-elevator enclosures eing rapidly superseded by construction which is more fire-resisting. The hitectural features of open grilles may still be retained for the fronts and doors uch elevators by using them in conjunction with approved wire-glass con-ction. In interior light-shafts and vent-shafts, openings must necessarily be vided, but here again the construction of the window-frames, sashes, and ing should be as far as possible as described on pages 901 to 903. When-the occupancy of a building admits, the stairs, also, should be inclosed in onry walls, with fire-proof doors at the openings. Unless so inclosed the rways form flues for the flames, and the stairs themselves, consequently, exposed to intense heat. In such situations, even absolutely fire-proof stairs d not be used during a fire, and possibly it is for this reason that greater s have not been taken to make them fire-proof. Shaft-walls should in all s be carried 3 ft or more above the roof.

eadening Properties of Partitions. The resistance to the passage of d through fire-proof partitions is an important consideration in buildings for living-apartments; and where the rooms are to be used as music-studios, comes a matter of still greater importance. In January, 1895, some tests made to determine the RELATIVE DEADENING PROPERTIES of the different itions shown in Fig. 76, the object being to decide upon the construction should be used in Steinway Hall, Chicago, Ill. The rank of the different itions tested, IN SOUND-PROOF EFFICIENCY, is shown by the numbers at the of the partition-diagrams. The 4-in porous partition was used, but was a success. In the Fine Arts Building, in the same city, double partitions, ar to No. 1, were used, and it is said that they were a great success. It is rising to note that in the tests above mentioned, the 2-in-solid-plaster par-n, No. 3, plastered with common mortar, ranked higher in SOUND-DEADENING ERTIES than those with double studs. In 1892 C. L. Norton tested the D-DEADENING PROPERTIES of partitions of several forms, for the purpose of ting a construction which was the most FIRE-RESISTING and SOUND-PROOF he dormitories of the New England Conservatory of Music, in which prac-y every room is a music-studio.* The various partitions were rated by ssor Norton as shown in the following table:

* The results of these tests, with a description of the partitions, were published in ance Engineering for August, 1902.

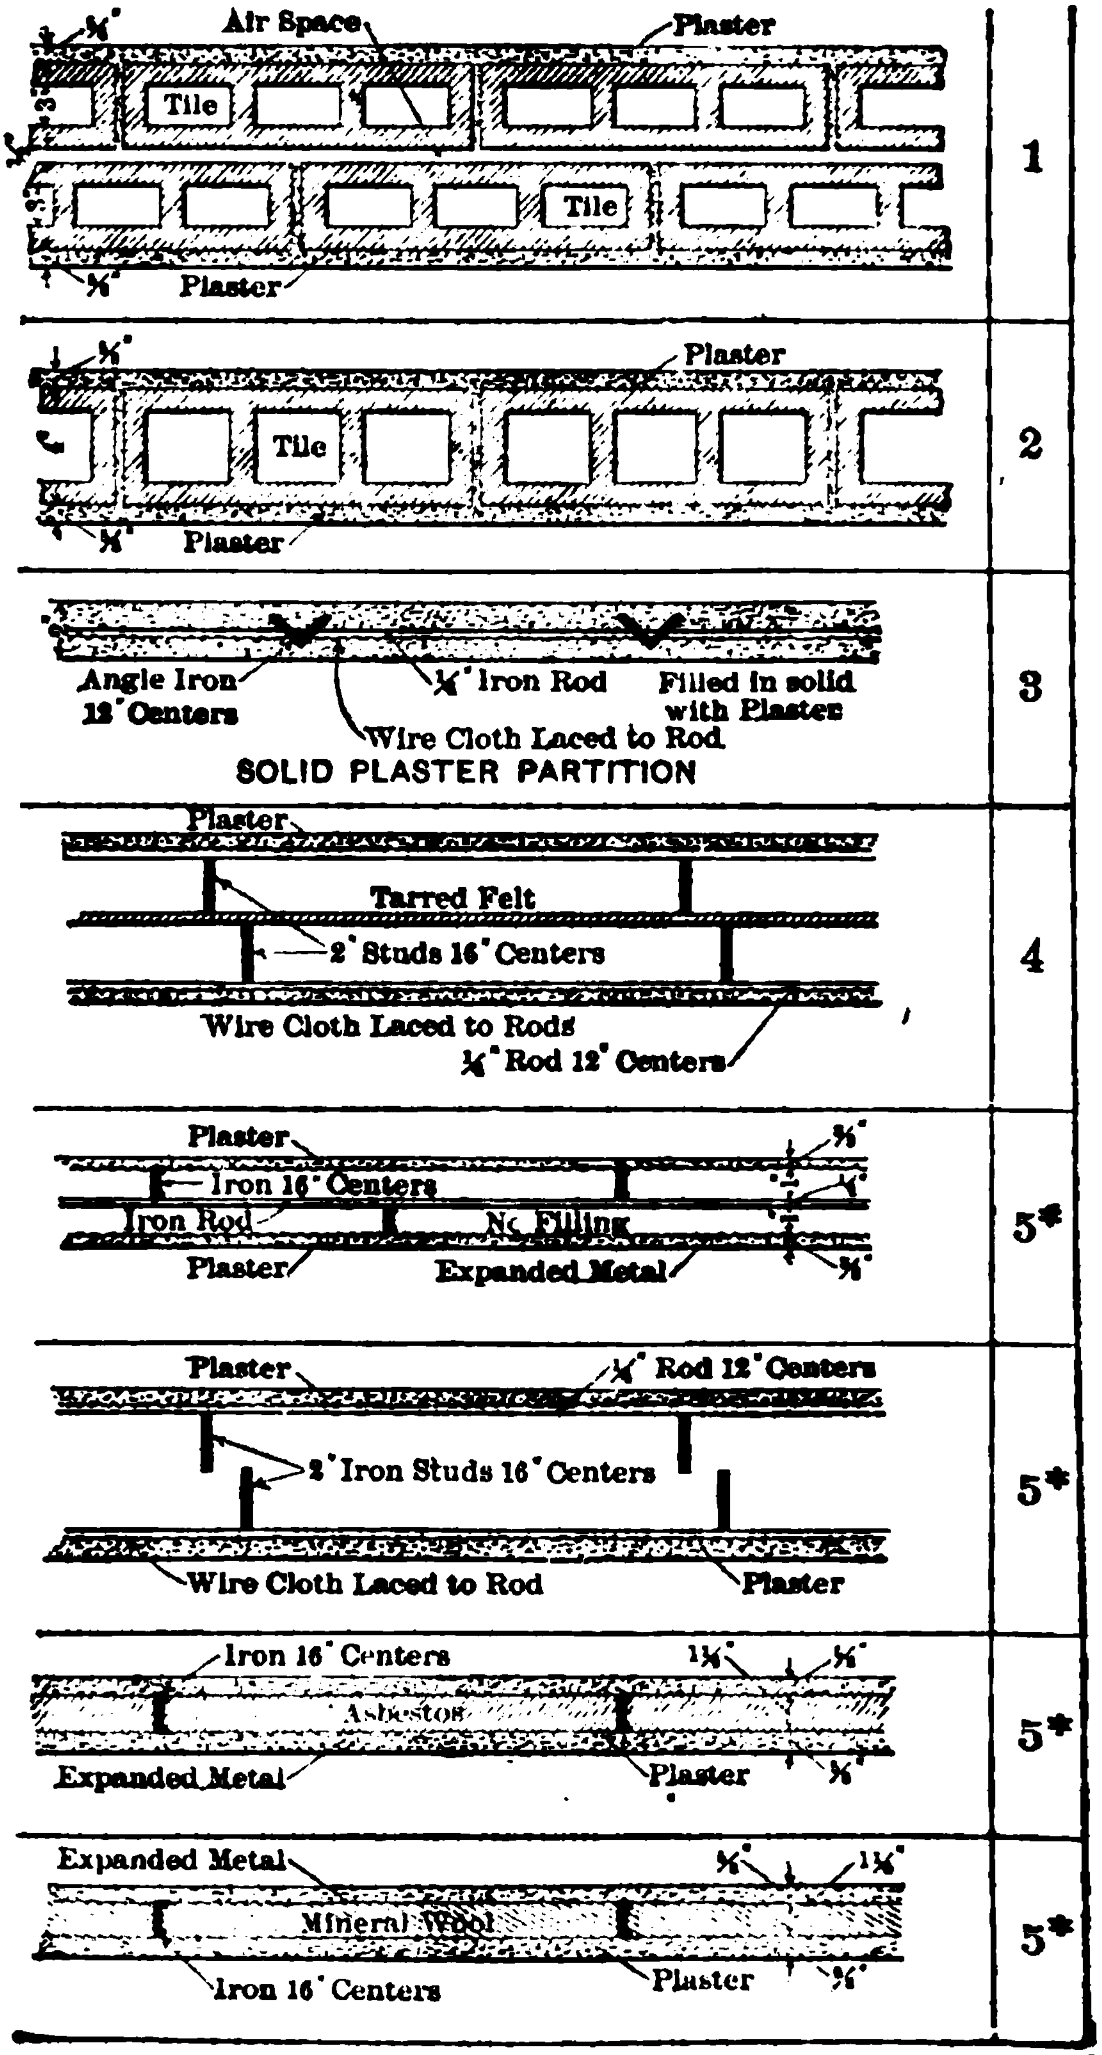

Fig. 76. Relative Deadening Properties of Partitions

Table XVI. Sound-Deadening Properties of Partitions

Room	Side	Scale	Composition
E	Left	100	Cabot's quilt, 3 thick and metal lath
E	Right	95	Cabot's quilt, 2 thick and metal lath
E	Rear	95	Cabot's quilt, 2 thick and metal lath
C	Rear	85	Sackett board, 2 felt on channels
C	Left	85	Sackett board, 2 felt on channels
C	Right	80	Sackett board, 2 felt
D	Rear	75	Metal lath and paper
D	Right	75	Metal lath, paper, and felt
B	Right	60	Two 2-in Keystone blocks with 2-in air-space

B	Rear	50	3-in Keystone blocks
A	Right	45	3-in National terra-cotta blocks
B	Left	40	2-in Keystone blocks
A	Left	40	2-in National terra-cotta blocks
D	Left	30	2-in metal lath, solid plaster

thing more is to be inferred from the numerical efficiencies, under 'scale
iat the first partition is about three times as good as the last, and that th
cal interval between any two partitions on the list merely indicates th
f the magnitude of the difference between the partitions." Professc
recommended a partition of Sackett Board and plaster with two thick
of Cabot's quilt between the plaster-boards, and this construction wa
l. The studding was put up the same as for the 2-in solid partition, th
cured to each side of the studs, and the plaster-board wired on to th
rough the quilt. This makes as light a partition, also, as it is possible t
ct. The investigations by Professor F. R. Watson of the University c
showed that 2-in solid, metal-lath partitions are more sound-deadenin
n hollow, gypsum-block partitions. Gypsum tile has been found to b
tisfactory than terra-cotta tile of the same thickness.

ng for Outside Walls. The outside walls of fire-proof buildings ar
y finished on the inside by plastering applied directly to the masonry
e walls are of brick, it is often desirable to fur them so that there will b
pace between the plaster and the masonry to prevent the passage c

Metal Furring. To produce architectural forms in the interior decorati of fire-proof buildings, METAL FURRING and METAL LATH are now almost un versally used. The furring is always of a sham nature, and never employ

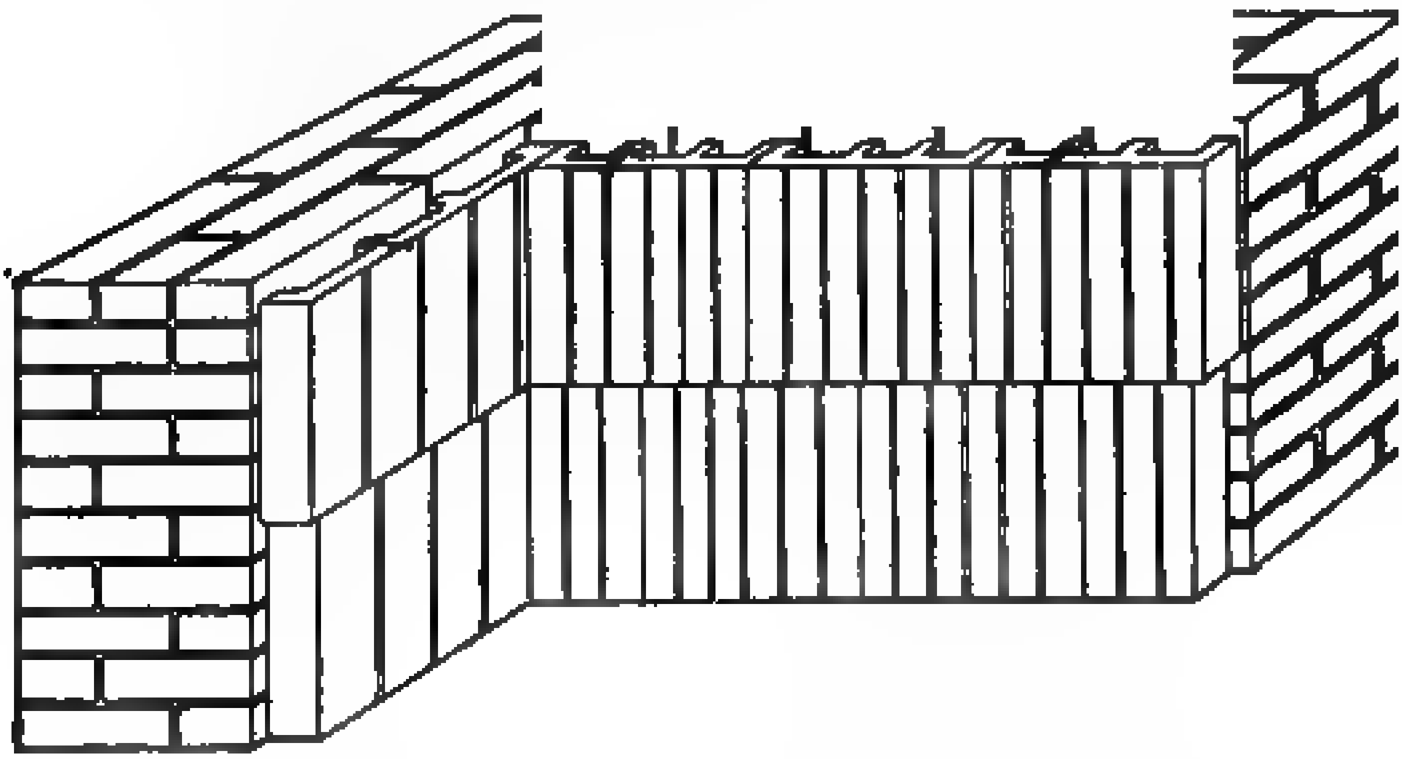

Fig. 77. Hollow-Tile Wall-furring

to carry loads of any magnitude; so that the only requirement is that it sh be incombustible and furnish a satisfactory ground for attaching the metal la For coves, cornices, false beams, etc., the furring-members are made of li bars, angles, tees, or channels, attached to the walls by means of nails, stapl or toggle-bolts, and to the steel beams by means of bolts, hangers, clips, e The furring-pieces are bent or shaped to the approximate outlines of the finish plaster-work, so that when the lathing is applied it will require not more th 1½ or 2 in of plaster to give the desired outline. For plane surfaces, the furri should be brought to within ¾ in of the plaster-line. Deep beams, etc., shou be braced by diagonal rods, to prevent distortion. All structural-steel memb should always be fire-proofed back of the furring. The lathing is secured the furring by means of No. 18 galvanized lacing-wire. The spacing of t furring should be either 12 or 16 in, according to the kind of lath that is to used. When chases in walls are covered over, the covering should be done w metal furring and lath. The casings for vertical pipe-lines, also, should be this construction and the space about the pipes at the floor-level should be fil solidly with fire-proof material, to cut off all connection between stories.

7. Fire-proof Flooring

Fire-proof Flooring. The floor-surfaces of most fire-proof buildings con of hard-wood flooring secured in the usual manner to nailing-strips embedd in the concrete or in the filling above it. It is sometimes advisable to use combustible flooring. The New York City Building Code requires that in buildings over 150 ft in height, the floor-surfaces shall be of stone, ceme tiling, or similar incombustible material, or of wood treated by some proc which renders it fire-proof. For warehouses and factories, floors finished w Portland-cement mortar are about as satisfactory as floors with any other ot floor finish; and cement floors have been much used for the guest-rooms

a. In the latter rooms, the floors are covered with carpets, which are ed to wooden strips embedded in the cement around the borders of the s. This makes a very sanitary floor, and one as easy for the feet as a car-l wooden floor. For public corridors, banks, lobbies, toilet-rooms, etc., the istic, vitreous, ceramic, or marble tilings are generally used. In France and any large quantities of cement tiles are used. Cement tiles have been in-iced into this country, also, but have not yet been able to compete with ncaustic tiles. In most buildings, however, the use of stone, cement, or tile ng is inadvisable. These materials are cold and trying to the feet. As a cement floor-surfaces do not wear well. Asphaltic flooring is sometimes but it is not pleasing in appearance. This material and different floor-ire discussed on pages 1604 to 1609. The characteristics of fire-proofed and its availability for this purpose are considered in the discussion of that ial on page 820.

mposition Flooring. Several attempts have been made to obtain a ig-material which could be spread, without joints, over an entire floor, t the same time be elastic, wear well, withstand water, acids, etc., and not expensive. Various mixtures of magnesite, asbestos, fine sand, sawdust with linseed-oil, and some binder like chloride of magnesium, have been the market under different names, all more or less meeting the require-above stated and being, also, fire-proof. These materials are shipped in rm of a dry powder to the place where they are to be used, and are there with a specially prepared liquid. The resultant is a plastic material is laid upon the surface to be covered in much the same way that ordi-ement or plaster is put on. The materials harden in from 12 to 24 hours lerately dry weather, when the floor is ready for use. When properly e floor presents a smooth, fine-grained, and continuous surface, resem-inoleum. These materials are made in various colors, such as red, white, brown, gray, black, blue, and green, and can be laid on wood, stone, e, asphalt, cement, or metals. Another advantage is that they can be up on the walls so as to form a covered base, without cracks or joints. the manufacturers furnishing such floorings may be mentioned: General lite Company, Long Island City, N. Y.; Marbleoid Company, New York Franklyn R. Muller & Company, Waukeegan, Ill.; and Ronald Taylor ny, New York City.

alt Mastic Flooring. This flooring is in the nature of an ASPHALTIC TE consisting of natural asphalt and a well-graded mineral aggregate of ravel, and crushed stone, ranging in size from that which passes a 200-reen to ⅜ in. The material is sent to the building-site in blocks and is roken up, reheated, and mixed with the coarser aggregate, the softened ing laid down in one or two courses, depending upon the thickness and smoothed down by rubbing with wooden floats. It is laid without tion-joints, the usual thickness being 1½ in, weighing 18 lb per sq ft. shed flooring is tough, ductile, water-proof, resistant to acids, alkali and re-proof, noiseless, and easy on the feet. It is especially suitable for and warehouses. It is manufactured by the H. W. Johns-Manville y, New York

8. Interior Finish and Fittings

or Finish. In buildings in New York City in which the flooring must ombustible material, the interior finish, also, including the doors, door-indow-frames, sashes, bases, and trims, must be made of incombustible

materials. The same materials that are accepted for flooring can be used fo this interior finish also. Several of the largest buildings in New York Cit including the Fuller Building, have all the trim constructed of FIRE-PROO WOOD. In the Hotel Gotham, all the doors and interior finish are made Alignum.

Metal Doors, Sashes, Frames, and Trim.* The effort to make the interi of buildings fire-proof has resulted in METAL-COVERED wood, and in door sashes, frames, trim, and moldings of HOLLOW steel or other metal. Many ver large buildings have in recent years been equipped wholly or in part with the products, and the products themselves have reached a stage of great perfe tion of workmanship and efficiency. Several cities in the United States comp the use of these products for certain parts of buildings which are over a certai height; and it is probably only a question of time when other cities will pa ordinances compelling their use. At the present time cost enters largely int the question of substituting them for wood. Among the first attempts in th United States to fire-proof the interior trim of buildings were those made i New York City, about the year 1880, in the form of metal-covered woodwor by the firm of Campbell & Bantossell of that city. About this time, als there were introduced along with various processes of fire-proofing woodwor FIRE-PROOF PAINTS. Later, FIRE-PROOF WOOD was introduced, that is, wo which has the resin and other inflammable components extracted from it, a the fiber left. In the course of a few years the METAL-COVERED-WOOD indust developed to such a stage that it was possible to trim with its products t interior of a building and keep a good appearance. Notable examples are t Manhattan Life Insurance Company's Building and the Barclay Building, an of more recent date, the Metropolitan Tower,† the Fifth Avenue Office-Buildin the Germania Life Insurance Company's Building, and the Vanderbilt Hot all in New York City; the Hoge Building, Seattle, Wash.; the Hall of Recor Los Angeles, Cal.; the Rockefeller Annex, Cleveland, Ohio, etc. The roug unfinished appearance of the STANDARD TIN-CLAD DOOR set men to seeking product for use in interior finish which would lend itself to more decorati effects. The KALAMEIN IRON and other METAL-COVERED work result In the meantime improvements were constantly being made in HOLL SHEET-METAL doors and trim, and from about the year 1903 HOLLOW STE construction for this work came into use. Owing to its generally super workmanship and to the splendid enamel surfaces which can be given it various baking-processes, this type of interior finish has found favor in the eyes the architects and owners of modern offices, and mercantile and public buildin

Kalamein Iron.‡ KALAMEIN IRON is the trade name given to one of t open-hearth sheet-steel products which is covered with a thin alloy of tin a lead in much the same way that galvanized iron by galvanic immersion coated with zinc. "The name CALAMINE (with Galmei of the Germans) commonly supposed to be a corruption of Cadmia. Agricola says it is fr

* For a brief outline of this subject, illustrated with numerous detail drawings, article on Metal Doors, Sashes, Frames, and Trim, by Professor Thomas Nolan, Kidder's Building Constructon and Superintendence, Part II, Carpenters' Work.

† The Metropolitan Tower has a metal-covered trim which is a special bronze-p construction over a wooden core. This was developed by The John W. Rapp Compa afterwards consolidated with The J. F. Blanchard Company into the United States Me Products Company, New York City.

‡ Among the better known manufacturers of metal-covered work, whose doors inspected and labeled by the Underwriters' Laboratories, Inc., are the United St Metal Products Company, New York City and the Thorp Fireproof Door Compa Minneapolis, Minn.

s, a reed, in allusion to the slender forms (stalactic) common in the formation."* The term KALAMEIN is often used incorrectly, by archid others, for any form of METAL-COVERED woodwork, whether the metal copper, or bronze, to distinguish metal-covered from HOLLOW METAL con-; but the term is obviously misleading and causes much confusion. In instances architects have specified KALAMEIN material expecting BRONZE o be used in the covering, whereas the manufacturer's interpretation of ification was that KALAMEIN IRON was intended.

l-Covered Doors, Frames, and Trim. The cores of METAL-COVERED d frames are built up of oak or white-pine strips dovetailed together se to the grain. In gluing up the strips into stiles and rails the grain strip is reversed in order to resist the tendency of the core to twist. s and rails are mortised, tenoned, and box-wedged, and the cores are with asbestos paper or board and enclosed with sheet metal, either steel ay be painted to match a wooden trim, or electroplated with copper, bronze), or solid sheet copper, brass, or bronze. For doors up to 3 ft idth and 8 ft in height, both sides are often made of continuous sheets which have the panels pressed into them by hydraulic pressure and are eam or joint. The metal sheets of the two sides, in one make of door,† to overlap in a depression on the edges of the door and are secured y screws which pass through both face-sheets. The standard thickness or is 2⅛ in. When these doors are more than 3 ft 4 in in width, each nerally made of two sheets which meet over a middle stile and lock with a flush double-lock joint. This makes a double row of vertical

-Covered Window-Frames and Sashes. Window-frames and sashes, door-frames and doors, are made of METAL-COVERED WOOD. Bronze tal usually recommended and preferred although Kalamein iron may tuted when a much cheaper construction is necessary. This cheaper y be painted and will give fair service but it is not recommended. d iron and copper, also, are used. "Window-frames and sashes of or of sheet-metal over wooden cores are principally used for or skylights where the only danger of fire-contact is through arks. They are NON-COMBUSTIBLE rather than FIRE-RESISTING. s are usually of plate glass, especially if KALAMINE trim is used comply with the law in those cities where non-combustible windows , etc., are required in buildings of a certain class or of a height d limits. Previous mention has been made of their efficiency as ted in the burning of the Kohl building in San Francisco, and their n as a substandard protection, has been pointed out; but for efficient nce, KALAMINE windows, especially, are an unknown quantity, as nce offered by the lighter members, such as sash-rails, is questionable. examples of the work present pleasing workmanship and finish. If osition could be used for the body instead of wood, without producing ction harmful to the metal, a superior type of KALAMINE work would h would be of great value."‡

Metal Finish in General.§ The transition from METAL-COVERED

the better-known manufacturers of hollow, sheet-metal doors, trim, etc., lstrom Metallic Door Company, Jamestown, N. Y.; the National Metallic

wood to HOLLOW SHEET METAL for doors, sashes, frames, trim, moldings, was naturally and easily made and to-day the latter type of construction, expertly carried out, results in details for interior work which are very eff to resist fire and handsome in appearance. It would be difficult to devise structional details which would be more satisfactory and at the same present greater possibilities in the way of elaborate design and high fi and it is on account of all these advantages that this type of construction is in the interior equipment of many of the best examples of fire-resisting b ings, especially for the doors, frames, sashes, and trim of corridors, hallw stair and elevator-enclosures, and even for entire office-partitions. Becau the non-absorbent character of the baked-enamel finish this material is pa ularly sanitary; and hollow metal doors are more easily cleaned than any ot especially if all moldings are omitted and panels made simply as smooth de sions. The thickness of standard hollow metal doors approved by un writers, varies from 1½ to 2⅛ in.

Hollow Metal Doors. The Dahlstrom patent SHEET-METAL DOOR made from two No. 20-gauge-steel plates, one stile and one panel-face formed from each of the sheets, which are connected by interlocking sean opposite sides of the panels and make practically a double door. In const ing the panels they are first lined with a sheet of asbestos next to the ste each side, and the space between is filled with a layer of hair-felt paper, makes a resilient filling that is a non-conductor of heat. The stiles ar hollow, but strips of cork are laid perpendicularly across the center of ea deaden the metallic ring. The panels are then attached to each other to the door by planting on and welding in place properly formed cross-rai the top and bottom, and wherever else they may be desired; the molding coped over the molded stiles at the sides. The top and bottom edges o door are then reinforced with channels and bars, and the doors made perf straight and rigid. The fire-resistance of this construction is increase letting no rivets or screws pass through from one side of the door to the in the exposed parts. The transmission of heat is thus avoided. Whil door is being put together, provision is made for attaching the hardware. the doors have been put together, they are sent to the finishing depart where the steel is thoroughly cleaned from all rust, grease, or other impu They are then given six or eight coatings of enamel, being baked afte application of each coat in large ovens which are heated to 300° F. the final coat of varnish is put on, they are usually rubbed to an egg gloss-finish, equal in quality to any hardwood-finish, and more durable be baked on. The surfaces can be grained to imitate with wonderful exac any wood, such as quartered oak, mahogany, Circassian walnut, etc. doors are to receive glass panels they are provided with detachable mol to hold the glass in place. Doors of the Dahlstrom, HOLLOW METAL typ installed in the corridors and partitions of the Singer Building and tower† the United States Express Building, New York City; the Bell Telephon change Building, Philadelphia, Pa.; the Seventh Regiment Armory, Ch Ill.; the Pontchartrain Hotel, Detroit, Mich.; the Bank of Commerce Bui St. Louis, Mo.; the First National Bank Building, Denver, Col.; an Royal Insurance Building, San Francisco, Cal. In some of the buildings

* Made by the Dahlstrom Metallic Door Company, Jamestown, N. Y.

† A severe fire in the twenty-sixth story of this tower was effectually confined room in which it originated by the doors of this type of construction.

n the preceding articles, HOLLOW METAL doors, trim, and moldings are anied by bronze or other METAL-COVERED WOOD window-frames, etc.

w Metal Door-Frames, Trim, and Moldings. After the HOLLOW door reached an advanced stage of construction the manufacturers their attention to the problems involved in making metal frames and s. It was found that moldings made by the ordinary HOT-ROLLED were too rough and heavy and required too much labor to smooth h their surfaces; and that those pressed from light-gauge steel by the methods were not clear-cut and definite in their outlines, and were n length and in variety of shapes. Accordingly, what is known as the AWN METHOD of making frames, trim, and moldings, was developed and l, and moldings made by this process are now used for many kinds of work. The cold metal is drawn through special dies to give it the shape and the bright finish is retained. The corners and angles come p and true and the pieces possess much greater strength and rigidity se HOT-ROLLED and several times thicker. There are dies for over a l shapes. Moldings can now be made in lengths up to 40 or even 50 xtra-freight rates and other drawbacks make it inadvisable to ship it s of over 20 ft. Besides the COLD-ROLLED special high-grade steel, onze, and copper are used in their manufacture. The rolled shapes ngles, channels, and Z bars; moldings for bases, cornices, wire-conduits, bs, sash-bars, panels, and glass; picture-frames, door and window-nd trims of all kinds; wainscoting and chair-rails; and numerous miscel-orts. WROUGHT-IRON welded one-piece door-frames are made for use oof partitions. These frames are constructed scientifically of specially ROUGHT IRON in several different shapes. The mitered corners are gether making the frame one solid piece. They are made for any or type of door or partition, require no bracing, and can be fitted with hinges if required.

Metal Window-Frames and Sashes. (See, also, Sheet-Metal for sting Window-Frames and Sashes, page 902). HOLLOW METAL window-d sashes, as well as those which are made of METAL-COVERED WOOD t iron, wrought iron, drawn bronze, cast bronze, etc., and glazed with , prism glass, electroplated glass, etc., are used in those parts of build-ich the exposure to fire is not great enough to require the use of hinged shutters, or where a more pleasing appearance is demanded than that rom the use of hinged or rolling fire-shutters. Owing to many im-s made in recent years, both in design and details of manufacture, SHEET-METAL window-frames and sashes are now ranked among the of those of moderate cost for general use. The National Fire Pro-sociation, by its recommendations and standardizations, and the labeling systems of the underwriters' laboratories, have been largely al in bringing about these improvements and results. About the vantage connected with the use of SHEET-METAL windows is a relatively rioration when neglected. The materials used for making HOLLOW dow-frames and sashes are galvanized iron or steel; copper; sheet metal, ed; and sheet metal, bronze-plated. The sashes are glazed with LAZE wire-glass where good appearance is an essential requirement, or D OR ROUGH wire-glass where a translucent material only is desired. lear glass, unwired, may be used when additional fire-resistance is not

The National Board of Fire Underwriters fix, within certain limits, constructional details, the maximum permissible sizes of openings for

glass, etc. The principal regulations have been very conveniently cond by Mr. J. K. Freitag.*

Solid Steel Windows. Where large window-surfaces giving maximum are desired, as in factories, the so-called SOLID STEEL WINDOWS are frequ used. They have been given this name because the frames and muntin made of solid, rolled-steel sections, jointed at their junctions or intersectio special methods, in some cases oxy-acetylene welded, so as to make strong stiff frames. The manufacturers generally carry stock sizes varying in ap mate widths from 3 to 6 ft, and approximate lengths from 3 to 9 ft. The panes are about 12 by 18 in. The movable sections, or VENTILATORS, are pi on horizontal axes, though a COUNTERBALANCE TYPE, also, is made for u hospitals and public buildings. Ventilators should not exceed 5 ft in direction, nor more than 18 sq ft in area. Among the principal makers a Detroit Steel Products Company (Fenestra), Detroit, Mich.; David Lu Sons Company, Philadelphia, Pa.; American Steel Window Company, Ch Ill.; and Truscon Steel Company, Youngstown, Ohio.

Electroplated Trim. This product is made by a process which consi electrically depositing a layer of copper on the outer surface of wooden mol or doors. The metallic deposit preserves the markings of the grain of the and makes a very presentable door A good sample of this work has be stalled in the United Engineering Building, New York City, by the New Central Metal Company of the same city. Some very fine work of this ki been done by the Hecla Iron Works of New York City, by electroplating fire-proof material known as Lignolith.

Cement Trim. Keene's cement has been used for many years for ru base-moldings, door and window-trim, etc., and in many European bui practically all of the interior finis this material. Any molding can b in it with good sharp angles, and it i ficiently hard to stand ordinary u Fig. 78 shows a door-opening with of Keene's cement. This detail c further improved by covering the w frame and door with thin metal. metal and cement can be painted sired.

Molded Hollow Tiles for I Finish. These are also being subst for the ordinary wooden finish. Amelia Apartments, erected by Camp at Akron, Ohio, in 1901,† i almost entirely of hollow tile. "The bases, the picture-moldings, an architraves around the doors were made of specially formed tiles, as in Fig 79. These tiles were afterward painted to harmonize with the s of color-decoration. All of the floors throughout the building are covered a cement composition composed of Sandusky cement and ground wood, tro down smooth and level."

FIG. 78. Door-jamb with Cement Trim

Metallic Furniture and Fittings. In offices, banks, libraries, and buildings, the furniture and fixtures are about the only articles on w

* For the principal regulations, conveniently condensed, see Fire Preventio Fire Protection, by J K Freitag.

† Described in the journal, Fireproof, July, 1903.

ted, if the building itself is fire-proof, and if these are made of incom- materials there is no chance for a fire to gain headway or to do much .

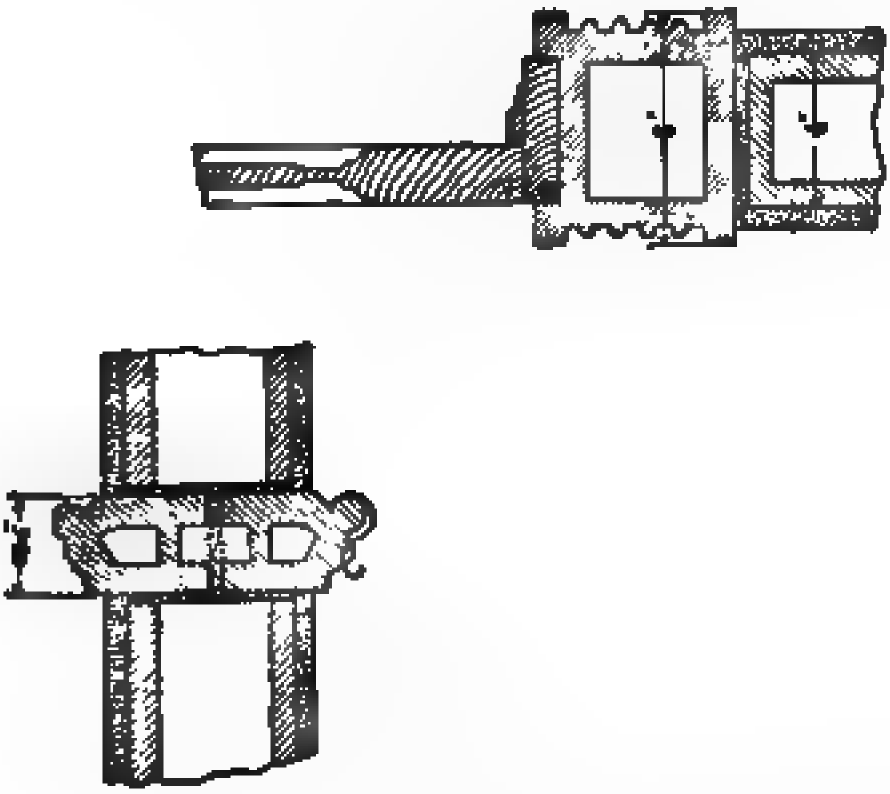

FIG. 79. Hollow-tile Door-trim, Picture-molding and Base

Almost anything in the way of furniture and fittings, including even desks and highly ornamental cabinets, may now be obtained in metal; y libraries, banks, and court-houses have been fitted up and furnished with incombustible cabinet-work. Catalogues can be obtained from ng companies engaged in ufacture of METAL FUR- such for example as the d Construction Company, n, N. Y., the Berger turing Company Canton, e Van Dorn Iron Works, d, Ohio, and the Library New York City and Bos- n.

FIG. 80. Hollow-tile Steps for Staircase

. In a majority of fire- ldings the architects have d themselves with putting BUSTIBLE STAIRS of iron, haps slate or marble treads. As pointed out in the first pages of this unprotected iron cannot be considered fire-proof, but it is difficult to e ironwork of a stairway, as it is usually built, and at the same time an ornamental effect. If exposed metal construction is to be used, cast uch to be preferred to steel, as the cast metal will retain its shape under at far better than thin facings or frameworks of steel. Slate and marble d platforms, unless supported underneath, should never be used in construction. When subjected to heat, marble and slate crack and fall ving the stairs impassable. A fire-department captain in New York his life through the collapse of a marble platform. If these materials used, therefore, there should be a subtread of iron or concrete beneath , really FIRE-PROOF STAIRCASE should be constructed with as little

ironwork as possible, and what ironwork there is, incased in FIRE-RESIS materials. It is possible and practicable to build stairs of clay tiles, brick reinforced concrete, that are absolutely fire-proof. The stairs in the Pe Building at Washington, D. C., are built of brick, with the exception o treads, which are and in many of earlier governm buildings the are of stone. S suitable for s however, are no resistant as cast to heat. Part Building Constru and Superintende contains descrip and illustration brick stairs. The tavino Company built several cases according system of constru using flat clay til bedded in cement, iron-work whate used in this struction; hence eminently fire- Fig. 80 shows tial section of a tile staircase such as was used in the Amelia Apar Building, Akron, Ohio. The blocks were of hard-burned material, and 4 ft long. They were supported upon the partition-walls and were by the mechanics for carrying up material during the erection of the

† From the Engineering Record, of Dec. 6, 1902.

at Washington, D. C. These stairs have steel girders and strings enclosed solid concrete, which is molded to form the steps and risers, as shown in the The steel strings, however, are hardly necessary, as the reinforcing-bars ifficient strength. Some excellent details for ornamental iron stairs were hed in Fireproof, March, 1903, in an article by J. K. Freitag. The cor-d sheet metal, known as Ferroinclave (page 851), offers a very conven-oundation for cement stairs. When built between walls or partitions h an open string, Fig. 82 shows one way in which the material has been the stairs being finished with about 2 in of cement over the metal and ed underneath. The Ferroinclave is bolted to lugs or brackets screwed ast on the strings. Slate or marble treads and risers may be embedded mortar if desired. (See, also, pages 947 and 983.)

9. Protection from Outside Hazard

ndow-Protection. To be thoroughly protected against the outside , buildings must have the openings in the outside walls provided with some of effectively closing those openings against flame. The same provision be made for openings in the partition-walls of large buildings. Four L TYPES of devices are in use for this purpose: (1) tin-covered wooden s; (2) steel shutters or doors; (3) metal frames and sash, glazed with ass; and (4) water-curtains.

s of Window-Protection Compared. When properly constructed, -COVERED WOODEN SHUTTER is still the most effective window-protection. ery severe fire in Lynn, Mass., in which the heat was intense enough to ost of the tin from the outside of the tinned plates covering the shutters, found afterward that the wood was charred to a depth of only about The shutters were warped slightly, but afforded sufficient protection the heat to allow men to remain behind them to put out such fire as nally crept through. This would not have been possible behind iron s under similar conditions."* STEEL SHUTTERS, under the action of arp very readily and transmit considerable heat. They belong to the t type of window-protection. "There is one objection to the use of s on window-openings, and that is that they depend on fallible human to be effective. They must necessarily be open while the building is When the need for them comes they are apt to be overlooked and are not Certain it is that on many buildings they are not closed at night."* TAL-FRAME-AND-WIRE-GLASS WINDOWS are not as unsightly as shutters st any kind are apt to be. They are more likely to be closed at night re readily closed when necessary. They do not hide a fire and are sily opened when it is necessary to reach a fire. The one serious objec-them is the intense radiation of heat from the wire-glass.†

overed Wooden Fire-Shutters and Doors. The effectiveness of vice depends on its construction. "Only well-seasoned non-resinous dressed, tongued and grooved in narrow boards, should be used. Wood ing moisture or resin may generate, under heat, sufficient steam or gas off the tin covering and expose the wood to the flame. The body of r should consist of two or three layers of such boards laid at right-angles ch other and fastened together by clinch-nails. The best grade of tin be used. No solder must be used, and the tin plates should be lock-

* Insurance Engineering, Dec., 1902.

† For a consideration of water-curtains, see page 903.

jointed, with the nails in the seams. The nails must be long enough, at l
1⅛ in, to secure a good hold beyond the depth to which the wood is likely
char, which is about ¾ in. Under intense heat the wood is certain to char,
if the nails are long enough to hold the tin up against the wood, and the
is properly put on so as to keep the air out to prevent burning, the shu
will stand under severe strains."* The hinges, fastenings, or hangers mus
bolted to the door, not nailed or screwed, as nails or screws would pull
during a fire. If hung on hinges, the hinge-hook should be built into the w
This door was designed for use in mills, but it has worked so satisfacto
that it is generally adopted wherever a fire-proof door is wanted and its
pearance is not objectionable. Fire-proof shutters, also, are made in this w
The National Board of Fire Underwriters issues complete specifications†
this type of door and shutter, and these specifications should be closely
lowed for satisfactory results. Doors of this type, provided for the openi
in interior partition-walls, are often, and wherever possible should be, hung
inclined tracks so that they will close automatically. Where it is desirabl
keep them open most of the time, an automatic release operated by a fus
link is provided. (See, also, page 778.)

Metal-covered Wooden Doors as Fire-Doors. Wooden doors cove
by the KALAMEIN or other process (page 894) are sometimes used as fire-d
where appearance is a consideration. They are not considered equal, howe
to the STANDARD TIN-COVERED WOODEN DOORS.

Steel Fire-Doors and Shutters. For a satisfactory STEEL FIRE-D
a ⅛-in sheet of steel should be used, and it should be reinforced on the b
with a frame of angle-irons, not less than 1½ by 1½ by ¼ in, and increasin
size with the door or shutter. These doors or shutters may operate in on
three ways: (1) swing on hinges, (2) slide on tracks, or (3) roll vertica
The SWINGING DOORS or shutters are the most reliable as there are no c
plicated parts to get out of order. They should be hung on eyes built into
masonry walls. SLIDING DOORS OR SHUTTERS must have the rails on which t
operate protected by metal shields to prevent obstruction. For larger openi
the ROLLING SHUTTERS are generally preferred. They are made in horizo
jointed sectional strips, which wind up on a roller placed in a pocket above
opening, the ends moving in metal grooves to hold them in place. They g
erally operate VERTICALLY, although some are made to operate HORIZONTAL
the rollers being set vertically in pockets at the sides of the openings. Th
latter are more apt to get out of order. The VERTICALLY operated door
shutters are balanced by springs or weights to make them move easily up
down. Where they are intended to be closed in case of necessity only, t
are slightly weighed and held open by means of fusible links, so that in cas
fire they will close automatically.

Sheet-Metal for Fire-resisting Window-Frames and Sashes.‡ Th
are now made weather-tight and perfectly practicable in all respects, and sh
be used wherever fire-resisting windows are desired. The sashes are m
especially for holding wire-glass. These SHEET-METAL WINDOWS are mad
a great variety of forms to meet all purposes and the sashes may be station
pivoted either horizontally or vertically, hinged, or double-hung with weig
like ordinary windows. For factories, warehouses, stairways, and elev
shafts, a stationary lower and a pivoted upper sash are commonly used, as t
is the cheapest type of window. The double-hung windows are now m

* Insurance Engineering, Dec., 1902.

† To be had for the asking.

‡ See, also, Hollow Metal Window-Frames and Sashes, page 897.

ork as smoothly as wooden sashes in ordinary box frames. For offices, ls, etc., a window having two sashes, glazed with wire-glass, and closing locking automatically in case of fire, and a third inner sash glazed with glass, has all of the advantages of an ordinary window with the additional ntages of fire-protection and better diffusion of light. Metal fly-screens can be used with these windows. All movable sashes, glazed with wire-, should be provided with a device by which the sashes will close and lock matically in case of fire. Two thicknesses of wire-glass are sometimes used a ventilated air-space of at least 1 in between the lights.

10. Extinguishing Devices and Precautionary Measures

ater-Curtains. "The vulnerable portion of buildings generally is the , where great window-openings are desired for purposes of light, and where considered objectionable on account of appearance to have shutters or wire-glass windows. These large window-openings afford great oppories for the spread of fire across streets. The danger of damage is much ased where the fronts, as is very common, are made of unprotected metal. A notable example, illustrating such danger, was the building of the hattan Savings Institution, New York City, which was severely damaged almost destroyed by a fire in a six-story non-fire-proof building across the t. Such conditions might be overcome to some extent perhaps, by the duction of some system such as the WATER-CURTAINS that were placed on hicago Public Library. This is practically a SPRINKLER SYSTEM set along dge of the cornice of the building, and so arranged as to furnish a thin of water in front of the building. Such a sheet will, however, not extend fore it is turned into spray and thus becomes practically useless. A similar gement placed at each window-opening might be more useful, though it btful whether it would be of much value in any severe conflagration."* rules of the National Board of Fire Underwriters for OPEN SPRINKLERS ter-curtains determine the sizes of piping and feed-mains, and the general gement of the system.

ecautionary Measures in General.† No matter how thoroughly a build- fireproofed, if it is filled with combustible goods, as a warehouse, store, or y, there is always the possibility of a fire, which, if unchecked when first d, must necessarily entail a great loss and more or less damage to the ng. If a fire is discovered and checked in its incipient stage this loss is ed. There are now many valuable devices for DETECTING and CHECKING which should be installed in every warehouse, and which often may be l with advantage in buildings used for other purposes. The more important se are automatic alarms, automatic sprinklers, and standpipes.

tomatic Alarms. The prompt discovery of fire generally brings about ot extinguishment, but as it is not practicable to have someone on duty in rts of a property at all times, fires may gain serious headway before being ered, unless some system of automatic notification is used. Next to auto- sprinklers, approved automatic fire-alarm systems, THERMOSTATS, are per- the most important of the fire-protection devices. There are two general s of thermostats: one which operates at a FIXED OR PREDETERMINED RATURE, and the COMPENSATING-TYPE. The latter requires a certain rise perature within a given time. This latter type is common in Europe, while s country the fixed-temperature-type has been preferred. The compen-

* Insurance Engineering, Dec., 1902.

† See, also, Chapter XXII, page 768.

sating-types seem to have been used with some success in certain sections, have not proved altogether satisfactory. For general use it would appear the SOLDER-TYPE OF THERMOSTAT has many advantages when used in connect with a simple CLOSED-CIRCUIT SYSTEM. The most common type of thermos system is the ELECTRIC SYSTEM, in which the thermostats are designed to o or close the electric circuit and cause bells to be rung at designated points. thermostats, or circuit-closers, may be of the fixed-temperature type or adjus to operate at any desired temperature. The former are chiefly of the SOLD TYPE, while the most common variety of the latter type consists of a SPRING TWO DISSIMILAR METALS, which expand unequally.

The Aero System. The best-known system of the compensating-type is AERO SYSTEM installed by the Aero Fire Alarm Company, New York Cit This consists of a small copper tube attached to the ceiling. A quick rise temperature, as in the case of fire, expands the air in the tube and acts on a sen tive diaphragm, which latter makes an electrical connection, causing a tra mitter to operate and send in an alarm.

The Reichel System is installed by the Pacific Fire Extinguisher Compa San Francisco, Cal. This system is of the COMPENSATING-TYPE, the REICH THERMOSTATS* consisting of a THERMOPYLE of special design which is connect in series with an electric circuit. Any rapid increase in heat generates suffici current to actuate a transmitter. Slow changes in temperature do not oper the system.

The Derby Automatic Fire-Alarm System is installed by the Americ Fire Prevention Bureau, New York City. This system consists of a TWO-WI CLOSED CIRCUIT, and uses the DERBY FIRE-SENTINELS,* in multiple, across line. Any derangement of the circuit gives a local or central station troubl alarm. Upon the operation of a SENTINEL THERMOSTAT, resistance is au matically cut out of the circuit, thereby causing the operation of fire-gongs a transmitters. The Derby Fire Sentinel can be used on wiring systems utiliz primary, storage, or public-service energy up to 110 volts. The Sentinels a made for attaching to open wiring and also for use in connection with conceal work.

The Watkins Thermostat is installed by the Automatic Fire Alarm Co pany, New York City. It consists of a perforated metal case, enclosing a FL SPRING OF TWO DISSIMILAR METALS. The spring is fastened at one end, and t heat causes a movement, due to the UNEQUAL EXPANSION OF THE TWO METAL WATKINS THERMOSTATS are wired in multiple, the wiring system being part op and part closed. The thermostats are adjusted by hand. They are likely to affected by corrosive influences, moisture, and rough handling. This syste however, has been more largely installed than any other, being the princip type of thermostat used in Boston, New York, and Philadelphia, where, wi good supervision, its record has been satisfactory.

Automatic Sprinklers. "An AUTOMATIC SPRINKLER is a device for distribu ing water by means of a valve which is arranged to open under the action heat, as from a fire which it is intended to extinguish. The distribution water which results from properly located sprinklers occurs in the form of rain of jets or drops, and is sufficient to drench almost any inflammable sto beyond the point of ignition. The distribution is also economical, as the wat is more evenly applied than from a nozzle attached to a fire-hose, and the sour is directly above the fire. Whenever combustible merchandise constitut the contents of a building, AUTOMATIC SPRINKLERS are of great value, and i

* Approved by the Underwriters' Laboratories.

ings of a height so great as to make the upper stories difficult of access, ially if containing large areas and very combustible contents, sprinklers itute the best protection obtainable."* SPRINKLER-SYSTEMS may be divided wo general types: (1) the WET-PIPE SYSTEM, or automatic sprinklers, just ibed; (2) the DRY-PIPE SYSTEM. Where the water cannot be kept from ng in the ordinary wet-pipe system, recourse is had to the dry-pipe system. sprinkler-pipes are filled with air under pressure, which is automatically ed by the opening of a HEAD-VALVE under heat. This release of pressure s the DRY VALVE in the main supply-pipe, allowing water to flow through prinkler-pipes and the open heads. Automatic sprinkler-heads are made pen at various temperatures: ordinary, 155° to 165°; intermediate, ; hard, 286°; and extra hard, 360° F. The higher-temperature sprinklers ut in locations where the heat is above normal, such as boiler-rooms and ooms. Various types, made by the following manufacturers, have been oved by the National Board of Fire Underwriters:† International ikler Company, New York City; General Fire Extinguisher Company, idence, R. I.; Automatic Sprinkler Company of America, New York City; der Brothers, St. Louis, Mo.; Esty Sprinkler Company (H. G. Vogel pany, New York, sole agents); Globe Automatic Sprinkler Company, delphia, Pa.; Independent Aetna Sprinkler Co., Philadelphia, Pa.; Ohio matic Sprinkler Company, Youngstown, Ohio; and Rockwood Sprinkler pany, Worcester, Mass.

rinkler Supervisory Devices. These devices consist of apparatus for NSMITTING SIGNALS when gate-valves are closed or open; when water in s falls below or is restored to a predetermined level; when pressure in nks falls below or is restored to a predetermined amount; when water ıks falls below or rises above predetermined temperatures; also to transmit r-flow signals and to withold signals from water-surges or variable pres-" They are used in connection with CENTRAL-STATION SIGNALLING ms for supervising the operation and maintenance of sprinkler-equip-s. The devices of the American District Telegraph Company of New City, are approved by the National Board of Fire Underwriters.†

nd-Pipes and Hose-Reels. In office-buildings, hotels, and apartment-s, where sprinkler-systems are hardly suitable, STAND-PIPES with HOSE- in each story and on the roof, ready for instant use, constitute the best s of quickly controlling a fire. All buildings over certain heights should equipped, the height being fixed by the ability of the local fire department ch effectively the upper parts of the building with its hose-streams. The pipe should be from 2½ to 6 in in diameter, according to the size and of the building, and should be connected with the water-supply of the ng and provided with Siamese connections at the street-level for the fire ment. Check-valves should be provided, so that when the fire-depart-ngines are attached, their force will be added to the force due to the head er from the fire-tanks, or to the fire-pumps, or to the force of the city system. Stand-pipes should be placed within the stair-enclosures. In ities the practise is to attach them to the outside fire-escapes of the g. The number and location of stand-pipes should be such that all parts building can be reached by at least one stream supplied by hose not ng 100 ft in length.

CHAPTER XXIV

REINFORCED-CONCRETE CONSTRUCTION *

By

RUDOLPH P. MILLER

SUPERINTENDENT OF BUILDINGS, BOROUGH OF MANHATTAN, NEW YORK CITY

1. Introductory Notes

Definition. The term REINFORCED CONCRETE is defined in the propose standard regulations of the American Concrete Institute as "an approved mi ture of Portland cement, with water and aggregates in which metal (generall steel) has been embedded in proportionately small sections, in such a mann that the metal and the concrete assist each other in taking stress."†

Historical Notes. The great value of concrete as a structural material whe subjected to compression only has been recognized for centuries. The use reinforced concrete, however, as a practicable and commercial form of constru tion is comparatively recent. It is true that as far back as 1869, Franço Coignet of Paris took out letters patent on a combination of iron and concret and that even before this, in 1867, the principle of reinforcing concrete with iro had been applied by P. A. J. Monier, a gardener of Paris, to the making of larg flower-pots; still, the general application to building-construction did not occu till about the middle of the last decade of the nineteenth century. In its develop ment it was first applied to bridge-construction. The discussion of the subjec in this chapter is confined to its use in the construction of buildings. Th earliest example of a building of reinforced concrete in this country, and probabl in the world, is that erected in 1875 by W. E. Ward, near Port Chester, N. Y. in which "not only all the external and internal walls, cornices, and towers we constructed of concrete, but all of the beams and roofs were exclusively made o concrete reinforced by light iron beams and rods." ‡

The Erection of Reinforced-Concrete Work. In general outline, a build ing operation in reinforced concrete consists in the usual preparations of the sit by excavation or otherwise, the provision of suitable foundations for walls columns, or other supports, the erection of a series of wooden molds or forms, th placing of the necessary steel reinforcement, the pouring of the concrete, an the removal of the forms after the concrete has set sufficiently to sustain itsel and the load that may come on it during construction. From the beginnin of the erection of the forms the successive steps are progressive, that is, th placing of the steel and pouring of the concrete are going on in the lower sec tions or stories while the forms are being erected for the upper sections or storie So that in a large operation the carpenters, the steel-setters, and the concreter may all be working at the same time, one set slightly in advance of the others without interference one with the others. These several steps in the operatio

† Proc. Am. Concrete Inst., Vol. XV, 1919.

‡ For a further and more extended history the reader is referred to the larger treatise on this subject and to Edwin Thacher's article in Engineering News, March 26, 1903.

nsidered in greater detail in Chapter-Subdivision 7, page 962, Erection of rced-Concrete Construction.

2. Materials Used in Reinforced-Concrete Construction

Materials used in reinforced concrete are CONCRETE and STEEL. The te forms the mass of the construction. Its proper use is to resist com-n. While it has some tensile strength the amount is so small and so e that it should always be neglected. STEEL is used for the reinforcing l as it furnishes the greatest amount of strength at the least expense. HT IRON could be used, but it is practically unobtainable under present ons, and, as already intimated, its use is not economical.

rete. The CONCRETE consists of a mixture of cement and some aggre- definite proportions, with the necessary water to cause the setting of the .

ent. PORTLAND CEMENT should always be used in reinforced concrete, hould always be tested before being used. Even in small jobs it is im- to know that the cement is strong and sound. In purchasing the cement, tificate of some reliable testing-laboratory should be made one of the ns of acceptance. Under all circumstances, it is always best to have ing done at some well-established and properly equipped cement-testing ry. The results of tests in temporary laboratories are often abnormal y lead to unnecessary controversies with the manufacturers. To be ole, a cement should meet the following requirements as called for in l specifications.*

FIC GRAVITY. The specific gravity of the cement should be not less o.

ESS. It should leave by weight a residue of not more than 22% on a sieve.

OF SETTING. It should develop initial set in not less than 45 or 60 min- ording as the Vicat or Gillmore needle is used, but must develop final in 10 hours.

LE STRENGTH. The minimum requirements for tensile strength for s of 1-in-square section should be as follows, and should show no retro- in strength within the periods specified:

NEAT CEMENT

's (1 day in moist air, 27 days in water)........... 600 lb per sq in

ONE PART CEMENT, THREE PARTS STANDARD OTTAWA SAND

's (1 day in moist air, 6 days in water)............ 200 lb per sq in
s (1 day in moist air, 27 days in water)........... 300 lb per sq in

ANCY OF VOLUME. Pats of neat cement about 3 in in diameter, ½ in the center, and tapering to a thin edge, should be kept in moist air for a 24 hours. The pat is then exposed in an atmosphere of steam, 1 in above ater, in a loosely closed vessel, for 5 hours.

pats, to satisfactorily pass the requirements, should remain firm and show no signs of distortion, checking, cracking, or disintegration.

e complete standard specifications see the latest Year Book of the Am. Soc. Mats. See, also, Chapter III, page 237, for the principal clauses of the last Specifications for Portland Cement, adopted in 1916 and effective January y the Am. Soc. for Test. Mats. The tensile strengths for neat cement are ed.

SULPHURIC ACID AND MAGNESIA. The cement should not contain more t 2% of anhydrous sulphuric acid (SO_3) nor more than 5% of magnesia (Mg The test for CONSTANCY OF VOLUME OR SOUNDNESS is of particular importa for reinforced-concrete work. When used in large masses an occasional b of concrete made with unsound cement may not seriously affect the final re but in reinforced-concrete building operations, where the different member the structures are comparatively small, the safety of the entire building be jeopardized by the use of a small amount of unsound cement in some im tant part, such as a column.

Aggregate.* By the term AGGREGATE is understood the materials, inclu the sand, mixed with the cement to make the concrete. In practically all c the sand is a necessary element.

Sand. "The SAND should be clean. One may obtain some idea of its cle ness by placing it in the palm of one hand and rubbing it with the fingers of other. If the sand is dirty, it will discolor the palm. Unless from a ban known quality, a sand should be tested for tensile strength of mortar, be using. Preference should be given to sand containing a mixture of coarse fine grains. Extremely fine sand even if clean makes a weak mortar and sh never be used unless with a large excess of cement."† Mortars composed of part Portland cement and three parts fine aggregate or sand, by weight, sh show a tensile strength of at least 70% of the strength of 1 : 3 mortar of the s consistency and of the same cement mixed with standard Ottawa sand. New York Regulations specify that fine aggregate shall consist of sand, cru stone, or gravel screenings, passing when dry, a screen having ¼-in-diam holes, and passing not more than 6% through a sieve having 100 meshes linear inch. The Chicago Regulations specify that not less than 45% shal retained on a screen of 400 meshes to the square inch. (See, also, page 241.)

Coarse Aggregate. For the COARSER MATERIAL OF THE AGGREGATE m materials are used and many others have been suggested. Its selection is erally dependent upon local conditions. If possible, gravel or crushed s should be used. Whatever is used should be a clean, hard substance that secure to the concrete the necessary strength; that is, the crushing stre of this material should be equal to or greater than that of the mortar used least at the age of 28 days. In any case, where no reliable information is t had on the strength of a concrete made from a given aggregate, careful inv gation should be made before such material is used. (See, also, page 241.)

Gravel. GRAVEL, like sand, should be clean. If dirty it should be wa before being used. To get the most satisfactory or uniform results, gr should be screened and graded and then mixed in definite proportions, as RUN OF THE BANK will generally not give uniform results. (See, also, page

Stone. The most satisfactory stone that can be used is TRAP-ROCK (u which term are included most of the rocks of igneous origin), because o toughness and great compressive strength. The GRANITES, as they are c mercially known, are considered by some equal in quality to trap-rock fo making of concrete. The presence of mica in considerable proportion in s of the so-called granites would seem to make them unsuitable. LIMEST

* See, also, Chapter III, pages 240 to 251. The data there on Aggregates, Pr tioning Materials, etc., relate more particularly to mass-concrete, while the da Chapter XXIV is intended to cover, more in detail, reinforced concrete.

† Treatise on Concrete, Plain and Reinforced, Taylor and Thompson, third ed 1916, page 12.

soft varieties are excepted, make excellent concrete as far as strength is rned. They would, however, seem to affect the fire-proof character of oncrete. (See Tables on page 956.) The harder and more compact TONES, also, may be used successfully, but great care must be exercised ir selection. CONGLOMERATE, which is in reality a hard, coarse sandstone, l give very satisfactory results. On account of their low crushing strength, or SHALE should not be used in concrete. Besides the stones thus far ned, broken BRICK, TERRA-COTTA, FURNACE-CLINKER and FURNACE-SLAG een suggested. In the selection of broken brick or terra-cotta, care must en to get hard-burned material. The crushing strength of such material well selected, is a little more than that of acceptable concrete, 28 days But ordinarily, commercial brick or terra-cotta will not meet the require- for a good aggregate, and these materials should be used only as a last and then only after careful investigation. (See, also, page 241.)

ders. FURNACE-CLINKERS should be clean and entirely free from com- le matter. CINDERS are often used where fireproofing is the primary ration, and no doubt good constructions may be obtained, with extreme y the use of clinker or cinder concrete, especially if the material is ground, d and graded as suggested for gravel. But in general practice the con- ; not uniform in quality and is unreliable in strength. It is therefore not red in this chapter. In Chapter XXIII, Fireproofing of Buildings, its liscussed on pages 817 and 818. (See, also, page 242.)

of Aggregate. The SIZE OF THE AGGREGATE may vary from ¼ to 2½ argest diametrical dimension, depending on the particular purpose for t is to be used. Where the mass of concrete is comparatively large the te may run as high as 3 in in size. This may sometimes be the case dations and in large piers and thick walls. In columns, girders, beams bs, very unsatisfactory results would be obtained if so large a stone were For such work no stone or other aggregate should be used larger than pass a 1-in screen. In important girders and columns, especially when forcing-bars are closely spaced, the size should be made even smaller so oncrete of viscous consistency is produced "which will pass readily be- nd easily surround the reinforcement and fill all parts of the forms." * AXIMUM SIZES allowed for the aggregate in reinforced concrete in the dif- ities are as follows: St. Louis and Buffalo, stone that will pass a ¾-in ring, "three-quarter-inch stone"; New York, Cleveland and Philadelphia, at will pass a 1-in ring; Chicago, stone passing 1-in-square mesh; San o, for floors and fireproofing, 1-in stone, for foundations, 2-in stone. so, page 241.)

r. "The WATER used in mixing concrete should be free from oil, acid, or organic matter." *

rtions of the Materials. The proper PROPORTION OF THE MATERIALS into the concrete is dependent upon the size and character of the mate- 1 cities in which there are regulations governing reinforced-concrete con- , the mixture to be used is generally specified. In the absence of other tions the most satisfactory and reliable mixture is, one part of Portland two parts of sand and four parts of stone or gravel. It is the mixture been used in most of the experimental work on reinforced concrete, e is therefore much trustworthy information to be had concerning it. se of large or important operations, however, great economy can often

* Trans. Am. Soc. C. E., 1917, Vol. 81, page 1115.

be effected by a preliminary study of the materials to be used and of th proper proportions. In general, for given materials, the most economical n ture is also the strongest. The old method of determining the proportion concrete by measuring the voids in the coarser particles by means of w poured into a box containing 1 cu ft of the material and then providing t quantity of finer material, assuming the cement the same as sand, is not t recommended. It does not give accurate or satisfactory results. A be method is to take the materials to be used and make trial-mixtures by var the proportions, always using, however, the same amount of cement and w These trial-mixtures are placed successively in a measuring vessel of fixed and tamped, and the height to which the vessel is filled for each mixtu noted. The proportions that give the lowest height, or result in the sma volume, will give the most satisfactory concrete. (See, also, page 242 and lowing pages.)

The best and most scientific method, however, is that known as the MECH ICAL ANALYSIS, devised by W. B. Fuller. In this method the available mater including the cement, are separated into the various sizes by means of a s of sieves; curves are plotted which indicate the percentages of the whole n which pass the several sieves; and from a study of these curves the proport of the different aggregates are determined. For a detailed description of method the reader is referred to the chapter on Proportioning Concrete in 1912 edition of the Treatise on Concrete, Plain and Reinforced, by Taylor Thompson. As an example of the saving possible, the following case, give the work just referred to, will be of interest.

"The ordinary mixture for water-tight concrete is about 1 : 2 : 4, whic quires 1.57 barrels of cement per cubic yard of concrete. By carefully gra the materials by methods of mechanical analysis the writer has obtained w tight work with a mixture of about 1 : 3 : 7, thus using only 1.01 barre cement per cubic yard of concrete. This saving of 0.56 barrel is equiva with Portland cement at $1.60 per barrel, to $0.89 per cu yd of concrete. added cost of labor for proportioning and mixing the concrete, because o use of five grades of aggregate instead of two, was about $0.15 per cu thus effecting a net saving $0.74 per cu yd. On a piece of work involv say, 20 000 cu yd of concrete, such a saving would amount to $14 800 amount well worth considerable study and effort on the part of those in res sible charge."

In the ordinances or regulations governing reinforced concrete of va cities the proportions to be used are generally prescribed. In New York, ' concrete for reinforced-concrete structures shall consist of a wet mixture o part of Portland cement to not more than six parts of aggregate, fine and co either in the proportion of one part of cement, two parts of fine aggregate four parts of coarse aggregate, or in such proportion that the resistance o concrete to crushing shall not be less than 2 000 lb per sq in after hardenin 28 days." In Chicago, various grades of concrete are specified with the mate compressive resistance, to be developed, from a mixture of 1 : 1 : 2 an ultimate strength of 2 900 lb per sq in, to a 1 : 3 : 7 mixture with a stre of 1 500 lb per sq in. In Buffalo and San Francisco the proportion is g as one of cement to six of aggregate; in Boston it is one of cement to fi aggregate.

Compressive Strength of Reinforced Concrete. For reinforced-con work no mixture should be used that does not develop a COMPRESS STRENGTH of at least 2 000 lb per sq in at the age of 28 days. The crus strength of various concretes is shown in the following table:

Table I. Compressive Strength of Portland-Cement Concrete of Different Proportions

ing Stresses for Reinforced Concrete. Some formulas for the
of reinforced-concrete construction provide for the use of the ULTIMATE
H of the concrete and the application of a FACTOR OF SAFETY. This
is not to be recommended as it necessitates either the test of the con-
the assumption of an ultimate strength. While it is undoubtedly de-
hat the concrete should be tested, this is generally impracticable when
ling is being designed. It should be done during construction and is
the best work, to make sure that the concrete is up to the require-
Various factors of safety from two and one half to ten have been pro-
Different factors of safety are used for different members of a structure
fferent conditions. This is another reason why it would be better to use
STRESSES than ULTIMATE STRESSES. The following WORKING STRESSES
mended for reinforced concrete that will develop a CRUSHING STRENGTH
b per sq in in 28 days:

e fiber-stress in compression.................... 650 lb per sq in
g-stress.. 40 lb per sq in
shearing-stress when all diagonal tension is re-
by the steel, and the steel-resistance to both
ive and positive moments is fully developed.... 150 lb per sq in
ompression....................................... 500 lb per sq in
ress between concrete and plain reinforcing-bars.. 80 lb per sq in
ress between concrete and suitable deformed bars. 100 lb per sq in

ives the stresses allowed by various building ordinances.

* Ultimate strength. † Elastic limit. The symbol ≯ indicates "equal to or less than."

a, 1 : 2 : 4 mixture; b, 1 : 1½ : 3 mixture; c, according to mixture; d, in piers and columns.

el **Reinforcement.** The function of the steel reinforcement is to take up ngitudinal and diagonal tensile stresses and in some cases, as in columns . beams reinforced at the top, to give additional compressive strength.

d **or High Steel.** Two grades of steel are used for the reinforcement, STEEL and HIGH-CARBON STEEL. MILD OR MEDIUM STEEL is used for all ıral shapes and is the ordinary MERCHANT-STEEL. It has an ultimate strength of from 60 000 to 70 000 lb per sq in, and its elastic limit is about lf the ultimate strength. HIGH-CARBON STEEL has a greater percentage ›on and is therefore more brittle. Its ultimate strength is about 105 000 › elastic limit about 55 000 lb per sq in. The use of HIGH-CARBON STEEL permit greater stresses in the reinforcement, and consequently a less t of steel and a greater economy in construction. On account of its greater ıess, however, it is liable to sudden failures under stress. It is also often to be cracked or broken when sent to the work, and unless it is very care-ıspected there is great liability of defective material getting into the ıre. Furthermore, much of the so-called HIGH-CARBON STEEL has been ın practice, after testing, to fall far short of the specifications. Its use is re to be avoided, unless special care is taken to secure an absolutely re-ırticle and to have it inspected and tested. For large, important work uld be desirable. Ordinarily, however, mild steel should be used, as com-ly it is manufactured and sold under such standard conditions that it is . As the modulus of elasticity of high-carbon steel is practically the same of medium steel, the deformation under any given loading is the same re is no special advantage in the use of one over the other. Steel meeting cifications of the American Society for testing materials* for reinforcing-recommended. See Table III. The phosphorus in the steel should not ›.10% for Bessemer steel nor 0.05% for open-hearth steel. For slab and eam-reinforcement where wire or small rods are suitable, steel manu-l from Bessemer billets may be used with a TENSILE STRENGTH of 105 000, IELD-POINT of not less than 52 500 lb per sq in.

ding Stresses for Steel. The generally accepted WORKING STRESS for . steel is 16 000 lb per sq in in tension. Tests have shown that in cases he failure of reinforced-concrete beams is due to the failure of the rein-nt, the stress in the metal had not more than reached the YIELD-POINT. int is somewhat lower than the ELASTIC LIMIT. The working stress in l, therefore, should be a fixed proportion of the yield-point or the elastic t is held by some that this ratio should not be as high as one to two, e nearly one to three, reducing the working stress in mild steel as given › 10 000 or 12 000 lb per sq in. In using high-carbon steel they would : a similar ratio of the elastic limit, whatever that may be, according to ·dinarily 20 000 lb per sq in is taken as the working stress for high-car-l. Allowable WORKING STRESSES in steel reinforcement in various cities ı in Table II, page 912.

on-Members. Reinforcement is used in a variety of shapes and com-ı, nearly all of them patented and some of them forming the basis for SYSTEMS. Where the reinforcement is employed to take up tension, ıam or girder, the BOND between the concrete and the steel is relied upon p the TENSIONAL STRESSES in the steel. The plain bars depend entirely ADHESION of the steel and the concrete for the action of the two mate-›mbination, or the full tensile strength of the rod is developed by anchor-›ds into the concrete at the ends, in which case the beam becomes more

NOTE. d is the diameter of the pin; t is the thickness or diameter of the bar.

ous to a trussed beam with the rod as the tension-member. In cross-
a, plain bars are usually round or square, though sometimes flat bars,
, tees, or other shapes are used. In regard to the use of square bars and
other shapes, it is contended that the edges start initial cracks in the con-
s it shrinks in setting. Twisted flat bars, when placed too near the sur-
the concrete, cause a spalling or breaking out of the concrete from between
nvolutions, when the steel is under stress.

mmercial Sizes. As a result of the shortage of steel during and since the
war, the larger producers of reinforcing-bars have agreed to eliminate
of the commercial sizes of bars formerly in use and are now limiting their
of bars to the following sizes:

Area	Equivalent to	Area	Equivalent to
0.110 sq in	3/8-in round	0.601 sq in	7/8-in round
0.196 sq in	1/2-in round	0.785 sq in	1-in round
0.250 sq in	1/2-in square	1.000 sq in	1-in square
0.307 sq in	5/8-in round	1.266 sq in	1 1/8-in square
0.442 sq in	3/4-in round	1.563 sq in	1 1/4-in square

ty in obtaining reinforcement will be avoided to a great extent by the
hese sizes in designing reinforced concrete.

rmed Bars. With the DEFORMED BARS the adhesion of the concrete to
el is supplemented by a MECHANICAL BOND due to the shape of the bar.
lowing deformed bars have been and are at present widely used.

Ransome Bar. The Ransome Twisted Bars (Fig. 1) are made of square
Bars should be "twisted cold with one complete twist in a length of not

1 in	1.0000	5.19	3.400
1⅛ in	1.2656	5.75	4.303
1¼ in	1.5625	6.50	5.313

lesh and Expanded Metal. Other types of tension-reinforcement, RE-MESH FABRIC and EXPANDED METAL in various forms, have been n Chapter XXIII, Fireproofing of Buildings. Wire fabric has come general use as a slab-reinforcement, as it resists temperature-cracks cking of the concrete from impact or shock. It is made in various h heavy longitudinal or carrying wires and lighter transverse dis-r tie-wires. Expanded metal is similar to wire mesh in providing nt in both directions, rigidly spaced and attached or fastened to-is additional advantage is claimed for it; it provides reinforcement ions, thus taking care of concentrated loads.

ng. Different methods have been used for ANCHORING the tension-forced concrete. In the Hennebique system of construction (Fig. 10) bars are used, the ends of the rods are split and flared out. In other s the ends of the bars are simply turned at right-angles in such is most suitable. In some instances nuts and washers have been he ends of reinforcing-rods. Where reinforced-concrete floors are nection with steel columns the rods are run through the web-plates ngle-brackets and secured with nuts.

L. The strengths of the BOND between concrete and steel for various rs and differing conditions are shown in Table IV. After the bond he reinforcement still acts in conjunction with the concrete, due to or FRICTIONAL RESISTANCE. Numerous tests have shown this fric-

tional resistance to be about two thirds of the initial bond-strength. BOND-STRENGTH for ordinary round or square-section bars may be taken at

Fig. 10. The Hennebique System

to 300 lb per sq in, depending upon the character of the concrete and the de of roughness of the steel. MECHANICAL BOND depends upon the shape of bar and the compressive and shearing strength of the concrete.

Table IV. Results of Tests on Adhesion Between Concrete and Steel

Kind of bar	Size tested in fraction of inch	Concrete	Age	Ultimate stre developed in l per sq in of su face in conta

(d) T. L. Condron. (e) Tests of Metals, Watertown Arsenal, 1904.
(f) No longer manufactured.

:-**Members.** In many of the tests on full-sized concrete beams, failure y the development of diagonal breaks near the supports. The first crack in a beam, with nothing but horizontal tension-steel at the is apt to occur when the maximum VERTICAL SHEAR is from 100 to 200 lb . Since the vertical shear is accompanied by a HORIZONTAL SHEAR of ensity in all parts of the beam, it was formerly thought that this diag- ire was due to these shearing-forces at the end of the beam and vertical or bent-up rods were provided to resist the horizontal shear. More sts have shown that the SHEARING STRENGTH of concrete is from 60 to he compressive strength, and that these cracks are diagonal and in the which could be expected from the THEORY OF DIAGONAL TENSION, tributes them to a combination of the shearing-stress with the hori- isile stress. The inclined cracks which first appear are due to a rupture acrete in tension. The most effective way to prevent this rupture is e reinforcement in the direction of the stress that is inclined upwards ie supports, as nearly as possible normal to the line of the diagonal 'ertical reinforcement could be used, but it would not act until def- or downward displacement of the concrete occurred on the side of the y from the support. If vertical stirrups are used for this reinforce- y must be spaced a less distance apart than the effective depth of the l they must be looped around, though not necessarily attached to, the bars. When inclined reinforcement is used, it must be rigidly at- the longitudinal members and spaced a less distance apart than the epth of the beam. The reason for this is that the magnitude and in- f the diagonal tension increases from the middle toward the end of the g inclined 45° where the horizontal tension becomes zero.

ihn **Bar.** In the Kahn Trussed Bar (Fig. 11) the attachment of the the tension-member is positively secured. The bars are square or

Fig. 11. The Kahn Bar

in cross-section with webs rolled on them at two diagonally opposite e stirrups are formed by shearing these webs through a part of their turning up parts, as shown in the cut. These stirrups may be placed n up in pairs or so as to alternate on opposite sides of the bar, making of the stirrups closer than when turned up in pairs. Another advan- ital to the use of this bar is that the greater effective cross-section in at the middle, the point of greatest bending moment with the usual 'wo disadvantages, however, are the separation of the concrete by bove and below the bar, and the limitation as to the effective stirrup- eep beams. This bar is controlled by the Truscon Steel Company, 1, Ohio.

1 Trussed Bar can be obtained in the sizes shown in table on page

Compression. The steel reinforcement in reinforced concrete is ain cases to assist in developing COMPRESSIVE STRENGTH when the iot sufficient for the purpose, as in the case of beams and girders with

Size, in	Weight per linear foot, lb	Area, sq in	Standard le[ngths] of diago[nals] in
½ × 1½	1.4	0.41	12
¾ × 2 5/16	2.7	0.79	12–24
1½ × 2¾	4.8	1.41	12–24–36
1⅛ × 2¾	6.8	2.00	36
2 × 3½	10.2	3.00	36

rods placed above the neutral axis, and columns with rods placed verti The use of the steel reinforcement in resisting COMPRESSION will be treated at length in Subdivision 3 of this chapter, in the paragraph Compression in Beams and Girders, page 941. On account of the uncertainty, howe the steel and concrete each receiving its proportionate share of the load, t of steel in compression should be avoided as much as possible.

The Position of the Reinforcement. The importance of the EXACT TION OF THE REINFORCEMENT in the concrete will become more apparent discussion of the design of beams. A slight displacement of the steel wi terially affect the strength. If the steel shifts upward the beam is weake it shifts downward the protection of the steel against rust or fire is reduce the so-called UNIT SYSTEMS the reinforcements, including the tension-ro stirrups, are so tied and framed together that after being placed in the the possibility of shifting their positions with respect to the other surfa the beam or to one another is practically entirely removed.

The Unit System. The particular advantages in the use of a UNIT SY of reinforcement is, as already indicated, the assurance that each and every

Fig. 12. The Unit System

of the reinforcement is in its exact relative position, and maintains that po during the placing of the concrete. The reinforcement for each beam or g is as carefully laid out as the location of cover-plates, stiffeners, connection-a and rivets in a built-up steel girder. It can consequently be thoroughl spected and checked before being placed in position. Being marked, its location is easily determined by the foreman on the job, from the ere plan After it is put in place a quick inspection will show at once wheth correctly placed or not, as it must fit and extend the full length of the Being fabricated OFF THE JOB there is less interference between workmen.

on can proceed while the molds are being made, and consequently peed in erection is possible. The frames are readily transported and : to get mixed than loose rods sent to the job.

nit System (Fig. 12) is the pioneer of this type of construction and ıctured by the American System of Reinforcing, Chicago, Ill. Its par- atures are the bending up of some of the longitudinal reinforcements ıupports and the use of round U-shaped stirrups, wound around the bars and allowed to shrink into place.

ummings System (Fig. 13) is manufactured by the Electric Welding ', Pittsburgh, Pa. The particular feature of this system is the forming

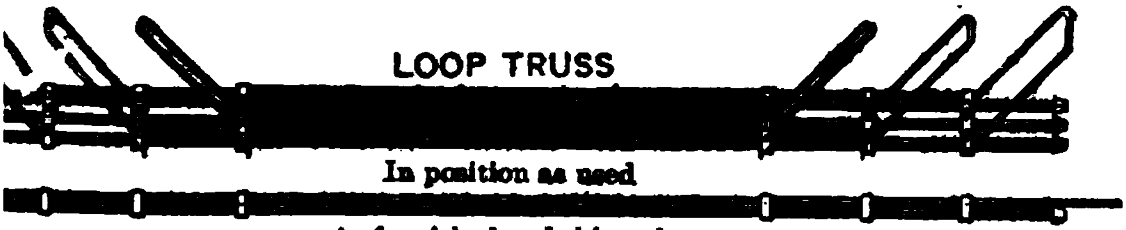

Fig. 13. The Cummings System

layer of small rods into rectangular frames which, after being fastened r layer at suitable points, permit the bending up of the ends to act as bers or stirrups, thus utilizing for shear the steel that is not required ; moments.

ten Truss. The Luten Truss (Fig. 14) consists of longitudinal rods ıate members bent diagonally upwards across the beam and con-

nclined web-members with a rigid anchorage at both top and bot- r by Professor Talbot on this type of reinforced beam, considerably than ordinary were obtained in vertical shear.

3. Design of Reinforced-Concrete Construction

Girders, Beams, and Slabs. Different formulas for the design of reinfo concrete girders, beams, slabs, etc., based on various theoretical considera have been devised by different investigators. The formulas here given have widely accepted and are offered because they are simple in form and give sat tory results. If anything, they err on the side of safety; and furthermore, have been found to give results closely in accord with actual tests. They are by the New York City Building Bureau, and are accepted by other authoriti

Assumptions in the Formulas. The formulas are based on the foll assumptions:

(1) The BOND between the concrete and steel is sufficient to make th materials act together.

(2) A PLANE CROSS-SECTION of a beam before bending remains a plane se after bending, and the stress and strain* in any fiber of either materia directly proportional to the distance of that fiber from the neutral axis c cross-section.

(3) The MODULUS OF ELASTICITY of the concrete in compression remains stant within the assumed working stresses.

(4) The TENSIONAL STRESS is taken entirely by the steel; that is, the t strength of the concrete is not considered.

Fig. 16 represents a longitudinal section and a cross-section of a reinfo concrete beam in a state of flexure or bending under a load. The fibers a

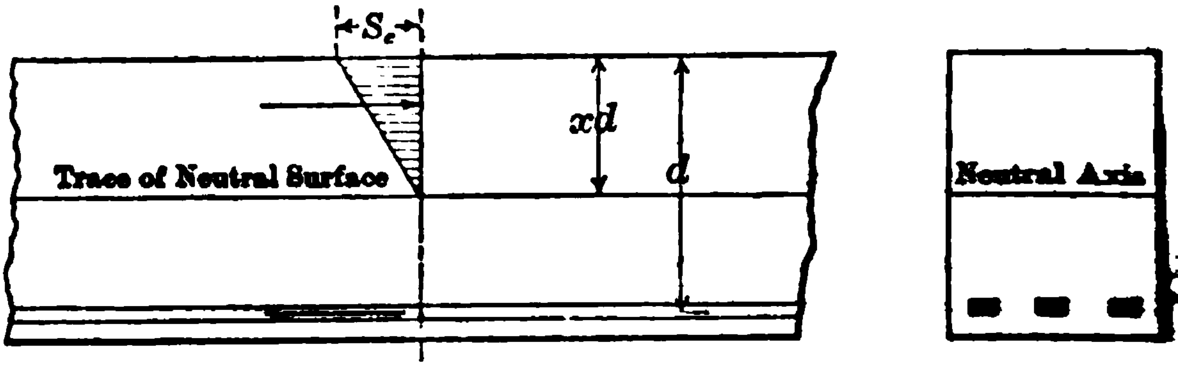

Fig. 16. Sections of Reinforced-concrete Beam

the NEUTRAL SURFACE of the beam or above the NEUTRAL AXIS of the cro tion are in compression and according to the assumptions the stresses v direct proportion to their distances from the neutral surface or axis, so th total area of compression in the concrete, representing the TOTAL COMPRE STRESS, may be graphically indicated by the shaded triangle. The TOTAL SIONAL STRESS may be assumed to be concentrated at the center of gravity cross-section of the steel reinforcement. One of the conditions of STATIC LIBRIUM for the beam is that the algebraic sum of all the horizontal stre the cross-section shall be zero; that is, that the sum of all the compr stresses, or the resultant compressive stress in the concrete, must equal th or resultant tensional stress in the steel.

Formulas for Reinforced-Concrete Beams. From these assump based upon THEORETIC and EXPERIMENTAL LAWS, the following formul derived, in which

S_t = the allowable unit tension or working stress in the steel in poun square inch;

* Deformation.

ı the allowable unit compression or working stress in the extreme fibers of the concrete in pounds per square inch;
the ratio of the modulus of elasticity of the steel to the modulus of elasticity of the çoncrete;
the effective depth of the beam, in inches; the distance from center of gravity of steel reinforcement to extreme fibers in compression;
the ratio of the depth of the neutral axis from the extreme fibers in compression, to the effective depth of the beam, so that
the distance of the neutral axis, in inches, from the extreme fibers in compression;
he width of the beam in inches;
the ratio of the cross-section of the steel to the cross-section of the beam, considering the beam all of that part of the concrete above the center of gravity of the steel;
the maximum bending moment at the dangerous section of the beam in inch-pounds;
:he moment of resistance, in inch-pounds, at the dangerous section of the beam, and must of course be equal to or potentially greater than the maximum bending moment;*
factor used for simplification of the formulas. This factor is constant for any given steel and concrete;
ectional area of the steel in square inches.
ns of rectangular cross-section

$$M = M_r = Kbd^2 \qquad (1)$$

f K being determined by the formula

$$K = S_t \left(\frac{1}{2\left(\frac{S_t}{S_c}\right)\left(1+\frac{S_t}{S_{c}r}\right)}\right)\left(1 - \frac{1}{3\left(1+\frac{S_t}{S_{c}r}\right)}\right) \qquad (2)$$

ıla can be deduced from the LAWS OF FLEXURE of beams and the ; noted above.
: of this formula for the value of K it must be remembered that the o S_c for any given ratio of steel to concrete, p, is a constant, so that ıg values of S_t and S_c must be used. This ratio, p, often spoken of :NTAGE OF REINFORCEMENT, is the expression in the first parenthesis d member of Formula (2)

$$p = \frac{1}{2\left(\frac{S_t}{S_c}\right)\left(1+\frac{S_t}{S_{c}r}\right)} \qquad (3)$$

ıent of resistance" or the "resisting moment" referred to any cross-section horizontal position and in a state of flexure under a load or loads is the ıf the moments of the internal horizontal stresses with reference to a point and the "bending moment" for that section is the algebraic sum of the the external vertical forces on either side of the section with reference oint (the forces on the left side being usually taken). The resisting ıse with the bending moments and in the flexure formula, $M = SI/c$ (see ıd X), they are made equal to each other, M being the bending moment resisting moment. In the following formulas, M and the expression :nt" generally, denote the maximum bending moment. M_{max} is often the latter.

The value of x is derived from the expression

$$x = rp\left(\sqrt{1+\frac{2}{rp}}-1\right)$$

Values for K and x for corresponding values of p, for different conditi fixed by the building authorities of different cities, are given in Tables V, VII and VIII.

Cinder Concrete. Values of K for cinder concrete are given in Tables I and X, which are, however, recommended to be used only for slabs. Cind concrete, though an excellent fireproofing material, lacks strength and shoul be used as a structural material for the slabs, only, between the beams.

Concrete Beams of Rectangular Cross-Section. In t BEAM required for any given case, r and the limiting nerally given, and K can be determined for any ratio, The value of M, the MAXIMUM BENDING MOMENT, th at the DANGEROUS SECTION of the beam, is determi loading, the span and the spacing; and the width a to be found. Formula (1) may then be put in the n

$$d = \sqrt{\frac{M}{Kb}}$$

A value for b is assumed and the equation solved for d. Architectural structural reasons will often limit the width or depth and several trials may ha to be made.

Reinforced-Concrete Slabs. For the STRENGTH OF SLABS the same formul apply. A slab may be treated (1) as a rectangular beam of unusual widt (2) as a series of beams set one alongside the other, the width of each beam bei equal to the spacing of the reinforcing-rods, and one rod being used for ea beam; or (3) as a series of beams of unit width, the area of steel for each bea being the area of reinforcement per unit of width.

Check-Formulas. It may sometimes happen that it is advisable to che a given or existing beam-construction as to strength or compliance with spe fications for working stresses. In that case the following formulas will l convenient (see, also, page 992):

$$M = pS_tbd^2\left(1 - \frac{x}{3}\right) \quad (6)$$

$$M = \frac{S_cxbd^2}{2}\left(1 - \frac{x}{3}\right) \quad (7)$$

If the strength of the beam for the assumed working stresses is to be dete mined, these values of S_t and S_c are inserted in Formulas (6) and (7), and th least value of M is used. If the values of M resulting from these equations a not equal, the full benefit of one of the materials is not being obtained. If th stresses in the steel or concrete due to a given loading are to be determined th formulas are put in the following forms:

$$S_t = \frac{M}{pbd^2\left(1 - \frac{x}{3}\right)} \quad (8)$$

$$S_c = \frac{2M}{xbd^2\left(1 - \frac{x}{3}\right)} \quad (9)$$

These formulas apply to rectangular beams only. M in Formulas (8) an (9) is the maximum moment due to the external forces, or the maximum ben ing moment. The value of x can be determined from Tables V to X. In Fo mula (8) it will be noted that the denominator of the fraction is an expressio for the area of the steel multiplied by the lever-arm of the resisting momen that is, the distance from the center of gravity of the steel to the center of com pression in the concrete. Similarly, in Formula (9), the denominator of th fraction is an expression for the area of the concrete in compression multipli by the lever-arm, x again being determined by Formula (4) and M being th maximum bending moment due to the external forces.

Reinforced-Concrete T Beams. Where beams or girders are used in rei forced-concrete building-construction there are usually accompanying floor-sla If these slabs are cast with the beams or girders they add very much to th strength of the latter, and when adequate bond and shearing-resistance are pro vided between the slab and the stem or beam, economical design requires th the slab shall be considered in determining the strength of the beam. The widt of slab that may be taken as part of the beam should not exceed one sixth th span-length of the beam, and the overhanging part on either side of the we or stem should not exceed six times the thickness of the slab. In any cas

ge must not be considered wider than the distance between the beams. ary floor-construction the spacing of beams, girders, and columns is gen- ı architectural or commercial consideration. Generally, the simplest pro- therefore, is to first determine the thickness of slab required for the given of beams, and this determines the thickness of the flange of the T beam. alculation of the girder, it is not objectionable to use the same slab, or of it as may be permissible, that has been used in the consideration of ı framing into that girder, as the compression-stresses, in the two cases, ght-angles to, and practically assist, one another. When, however, the slab-reinforcement is parallel to the girder, in the case of a combined m. and girder-construction, the slab-action produces compression in the ection as the girder-compression with a resulting overstress in the con- n this case, transverse reinforcement should be provided at right-angles rder and extending well into the slab.

ılas for Reinforced-Concrete T Beams. Fig. 17 shows a cross-sec- T beam resulting from the use of the slab as part of the beam, and

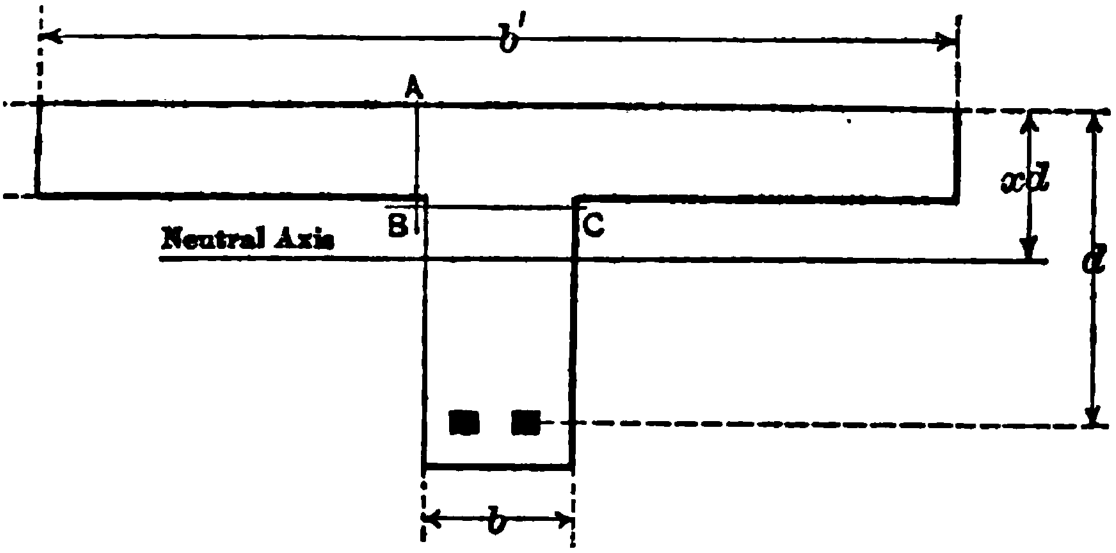

Fig. 17. Cross-section of Reinforced-concrete T Beam

ırly, also, the notation used in the formulas. In a construction of this : cases may be considered:

The neutral axis may fall below the flange, in which case

$$M = S_t A_s \left(d - \frac{t}{2}\right) \tag{10}$$

$$M = \frac{S_c}{2} b't \left(d - \frac{t}{2}\right) \tag{11}$$

formulas the small area of concrete in compression below the flange d and the center of compression is assumed to be at the center of This is done to simplify the formulas. The result is not materially ıd errs on the side of safety. The position of the neutral axis is given a (12)

$$x = \frac{2rd\,A_s + b't^2}{2d(rA_s + b't)} \tag{12}$$

›st economical percentage of steel by Formula (13)

$$p = \frac{S_c b't}{2\,S_t bd} \tag{13}$$

Case 2. The neutral axis may coincide with the under side of the flange, in which case

$$M = S_t A_s\left(d - \frac{t}{3}\right) \tag{14}$$

and

$$M = \frac{S_c b' t}{2}\left(d - \frac{t}{3}\right) \tag{15}$$

The economical value of p in this case is the same as in Case 1, Formula (13).

Case 3. The neutral axis may fall above the lower edge of the flange. This case is the same as Case 2, since for purposes of calculation all the concrete in the flange below the neutral axis is neglected and t becomes xd in this case as in the last.

Alternate Solution for Cases 2 and 3. In Cases 2 and 3 the section may also be considered as rectangular, with a depth d and a width b', and the formulas for rectangular beams, (1) to (9), may be used. Tables V, VI, VII, and VIII are also applicable in these two cases.

When the slab is considered an integral part of the beam, adequate bond and shearing resistance between the slab and the web of the beam must be provided. The concrete is ordinarily adequate to take the vertical shear through the flanges next to the stem, and is further strengthened by placing horizontal steel reinforcements across the top of the beam or girder, as described above. Whether or not the resistance to shear is adequate can be determined by the formula

$$S_s = \frac{S_h b\,(b' - b)}{2\,t} \tag{16}$$

in which S_s is the unit vertical shear at AB, and S_h is the unit horizontal shear at BC (Fig. 17). This should not exceed the safe unit shear for concrete unless steel reinforcement is provided. The value of S_h in the formula is

$$S_h = \frac{V}{b\,(d - \frac{1}{3}t)} \tag{17}$$

which, it will be noted, is the total vertical shear divided by the effective area of the stem.

Moduli of Elasticity. In the derivation of all these formulas and in the determination of the values of K, the ratio of the MODULUS OF ELASTICITY of the steel to that of the concrete plays an important part. It is necessary then to know what values to use. The generally accepted modulus of elasticity of steel is 30 000 000 lb per sq in. The modulus of elasticity of concrete varies with many conditions. Even in the same mixture, the character of the materials as well as the manner of mixing and placing, affect it. The modulus increases with the age of the concrete. It also increases with the richness of the mixture. It seems to decrease with an increase in the load on the concrete. It should also be noted that the modulus of elasticity as determined from a beam in flexure is greater than that determined from compression-cylinders. Moreover the modulus of elasticity as determined from compression varies with the point selected on the stress-strain curve. The different values for the RATIO OF THE MODULUS OF ELASTICITY of the steel to the modulus of elasticity of the concrete to be used in the design of reinforced-concrete construction, as fixed by the building regulations of various cities and by other authorities, is given in Table II, page 912. Values for the modulus of elasticity of concrete under different

for different mixtures determined by actual tests at the Watertow
e given in Table XI.

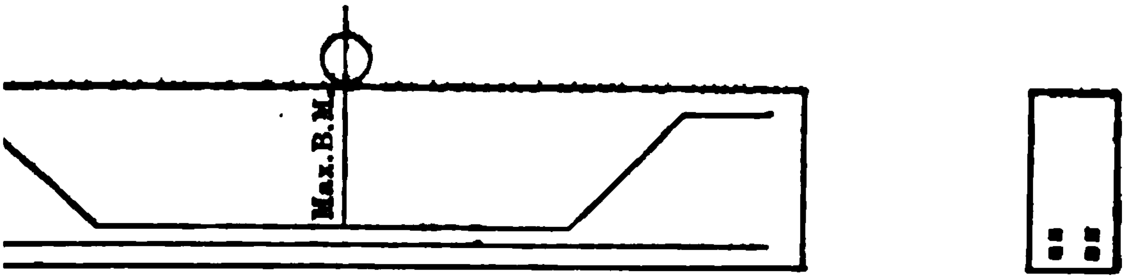
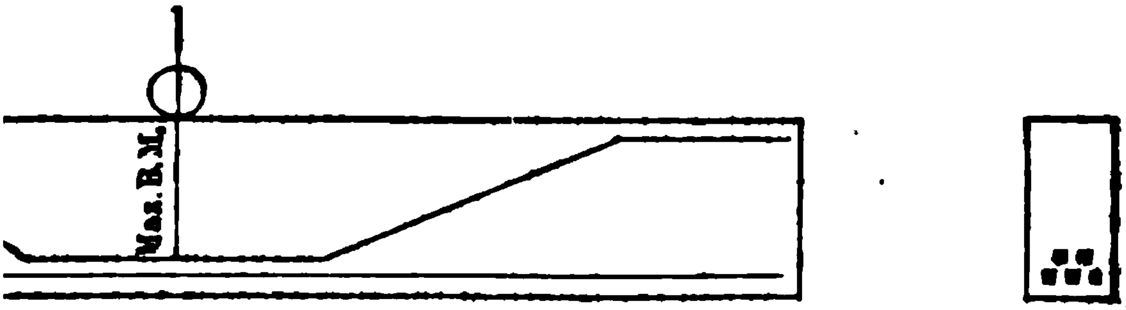
substituted in Formula (5). For M in that formula, the MAXIMU
OMENT due to the external forces is used.

; **Moments in Beams.** Beams and girders are usually consider
BEAMS, that is, as beams supported at both ends, but not built i



Reinforcement for Uniformly Distributed or Symmetrically Placed Load



9. Reinforcement for Unsymmetrically Placed Concentrated Load

r continuous, although in many instances they are actually carri
US BEAMS, over the supports. If continued over a support, th

is a NEGATIVE BENDING MOMENT at that support, and this negative bending m ment should be taken care of by reinforcements in the upper part of the bea This bending moment is one half that at the middle of a simple supported be loaded at the middle, and two thirds that at the middle of a simple support beam, uniformly loaded. In the case of simple supported beams loaded eith at the middle or with a uniformly distributed load, the bending moments crease toward the supports. For these reasons it is advisable in arranging t steel to be used for the tensional reinforcement, to select the bars or rods pairs, so that, as the supports are approached, a part of the reinforcement m be turned up toward the top and carried across the supports near the top as dicated in Figs. 18 and 19. For continuous beams and slabs with uniform distributed loads, the following are recommended for MAXIMUM POSITIVE a MAXIMUM NEGATIVE BENDING MOMENTS:

"For beams, the bending moment at middle and at support for inter spans, should be taken equal to $wl^2/12$, and for end spans it should be tak equal to $wl^2/10$ for middle and interior support, for both dead and live loads.

"In the case of beams and slabs continuous for two spans only, with their en restrained, the bending moment both at the middle support and over the midd of the span should be taken equal to $wl^2/10$."*

Beams simply supported at the ends must be considered as SIMPLE BEA with maximum positive bending moments equal to $wl^2/8$. In all the abo values, w is the load per linear unit and l the span in the same unit.

Bending Moments in Slabs. As floor-slabs are usually carried continuou across the supports, the maximum bending moment due to a uniformly distri uted load is assumed to be less than in beams simply supported at the en The New York City Regulations provide that "the bending moments at t center and at intermediate supports of floor-slabs continuous over two or mo supports shall be taken as $Wl/12$." The same regulations provide that "the ben ing moments of slabs that are reinforced in both directions and supported four sides and fully reinforced over the supports (the reinforcement passing in the adjoining slabs) may be taken as Wl/F for loads in each direction, in whi $F=8$ when the slab is not continuous or when continuous over one suppo and $F=12$ at both center and supports when the slab is continuous over bo supports." In these expressions W is the total distributed load and l the sp In square slabs with two-way reinforcement it is usually assumed that the loa ing is uniformly distributed and that half the load is carried by each system. rectangular slabs the amount of load carried by each system of reinforcement given by the formula

$$r = \frac{1}{2}\frac{W}{n} \qquad (1$$

in which r is the proportion of load carried by the transverse reinforcemen W the total load on the slab, and n the ratio of its longer to its shorter sid Using this proportion of load, each set of reinforcements is calculated as a sl with supports on two sides only, and the total number of rods required is d termined on the assumption of equal spacing. The rods may then be spac uniformly at the usual spacing for the central half of the slab and gradually r duced in number per foot of width to the edge of the slab, using one half many rods for the remaining two quarters. In this way, the amount of reinforc ment is reduced 25%. When the length of the slab exceeds the breadth by 50% the stresses in the longitudinal steel become so low that the construction

* Trans. Am. Soc. C. E., 1917, page 1127.

onomical. The slab should then be treated as one with a one-way reinforce-t.

rinkage-Stresses and Temperature-Stresses. In slabs resting on or ed over two supports some reinforcement should be provided at right-s to the tension-rods to provide against SHRINKAGE-STRESSES and TEM-TURE-STRESSES. Incidentally, this reinforcement may also serve to keep tension-rods properly spaced. In general it should not be less than one d of one per cent in amount and well distributed. It is common practice e from ¼ to ⅜-in rods, spaced about 2 ft apart. Deformed bars with irregu- surfaces and reinforcements of small diameters, placed as close as practi-le to the surface, are most effective.

The Disposition of the Steel. In designing the reinforcement for any m of loading, the full sectional area required must be provided at the point MAXIMUM BENDING MOMENT. As the supports are approached, part of the inforcement, as already indicated, is turned up, but care must be taken to keep so distributed that at any point there is still sufficient reinforcement below e neutral axis to furnish the necessary tensional resistance. The arrangement reinforcement for a uniformly distributed or symmetrically disposed load is own in Fig. 18, and for an unsymmetrically placed concentrated load, in Fig. 19. the first instance the maximum bending moment is at the middle of the am, the reinforcement is symmetrical about that point, and as much as one lf the amount of reinforcement may be turned up. In the second instance e maximum bending moment is at some other point than the middle, the rein-rcement must be so disposed that the full amount required will be under the ad or at the point of maximum bending moment, and the turning up must done between that point and the support. Other conditions might require s than half the reinforcement to be turned up. There is another reason for rning up the reinforcements toward the ends. In addition to the resistance the NEGATIVE BENDING MOMENT, there is a resistance to the SHEAR offered the metal running through the concrete at the points where the DIAGONAL NSION occurs.

The Percentage of Reinforcement. The AMOUNT OF THE REINFORCEMENT any case is determined by Formulas (3) and (13) for rectangular and T beams spectively. The values obtained by these formulas give the most econom-l amount. This may vary from ¼% to 1¼% of the cross-section area of ncrete, but will usually run about 7/10%. The nearest stock size of rods ving this amount or a slightly greater amount can be selected from the table ven on page 1514, or from the catalogues of the manufacturers of the various formed bars.* The NUMBER OF RODS used to make up the necessary ctional area must be determined by considerations mentioned in the follow-g paragraphs.

The Number of Reinforcing-Rods. As already suggested, an even number apts itself better to a symmetrical or balanced arrangement both in cross-sec-n and horizontal section. One rod does not permit of the turning up toward the pport. Two rods may be made either to continue along the lower edge of the am, or one may start at one support, run along the lower part and turn up be-nd the middle as it approaches the second support; and the second rod run milarly along the bottom from the second support and turn up after passing the iddle as it approaches the first support. Three rods may be arranged so that o continue along the bottom and the third, the middle one, turns up as it ap-oaches the supports. The arrangement for 4, 5, or 6 rods will naturally suggest

* See, also, paragraph on Commercial Sizes, page 915.

itself from what has been already said. Too large a number of rods is not sirable, as a large number of them together acts more or less as a screen for coarser particles of the concrete and prevents a close contact between it and steel. This matter of complicated reinforcement is one of considerable pract importance. If, however, the steel is satisfactorily incased with concret larger number of small rods is preferable to a small number of larger o The AREA OF CONTACT of a rod of smaller size is proportionately greater t that of a rod of larger size, as the perimeter varies directly as the diameter, the sectional area as the square of diameter of the cross-section. In order a rod may not slip, the ADHESION of the steel to the concrete must be equa or greater than the tension in the steel.

The Adhesion Required. The tension in a reinforcing-rod at any p having been determined from the given formulas, it must next be determi if, in either direction from that point, the AREA OF CONTACT of the stee large enough to make the total ADHESION equal to or greater than the TENSI If there is a deficiency in this respect it must be made up either by a mech cal bond or by anchoring the reinforcements at the ends. Safe VALUES ADHESION of concrete and steel are given in Table II, page 912. A safe to apply, without calculation, to the case of beams with a maximum bend moment at the middle, is to make the diameter of the rods not more than two-hundredth of the span. Under ordinary conditions, generally speaking, length of rod on either side of the point of maximum bending moment should at least eighty diameters for plain rods, and not less than fifty diameters deformed bars. Under unusual conditions the adhesion should be carefu studied. The apparent discrepancy between the first and second statement this paragraph is explained by an allowance made and based upon the fact the tension in the steel does not decrease uniformly with the decrease in tance from the supports. The allowance is purely arbitrary but is conside safe. For cases of unsymmetrically loaded beams it is best to examine ca fully into the conditions.

The Separation of the Rods. It has not been unusual in tests on bea to have the concrete split off from the under side along the line of the reinfo ment. This is due in part, if not entirely, to an insufficiency of concrete betw and around the reinforcement. To avoid this the SPACING or SEPARATION the reinforcing-rods in the cross-sections of the beams must be such that resistance of the concrete to SHEAR at the level of the rods is at least equal the ADHESION of the concrete to the steel. As a general rule the rods should spaced not less than two-and-one-half diameters on centers and about two ameters from the sides of beams. The clear distance between rods and the sp between rods and edges of beams should in no case be less than 1½ in. I formed bars, if stressed to their full tensional value, should be spaced fart apart than plain bars. At the middle of a beam, the BOND-STRESS is low, but the top of a continuous beam, over the supports, where the negative moment creases rapidly, the bond-stress is apt to be excessive and frequently limits diameter of the reinforcement.

Provisions against Shear or Diagonal Tension. Numerous tests of bea reinforced with horizontal rods without stirrups or inclined reinforcement h shown that DIAGONAL CRACKS occur when the maximum shear over the cro section is from 100 to 200 lb per sq in. Tests conducted on concrete with purpose of eliminating all other stresses but direct shear have given a SHEARI STRENGTH of concrete of from 800 to 1 600 lb per sq in. The ordinary conc beam has, therefore, a cross-section of sufficient area to withstand a SHEARIN STRESS of 200 lb per sq in. The cracks always occur at points where a la

G-STRESS exists in combination with MOMENT-STRESSES.
l loads, DIAGONAL-TENSION failure occurs under the co
a simple beam under a uniformly distributed load, the cr
supports. The inclination of the diagonal tension in the co
nt of two forces, changes, therefore, with the variations of

ams with horizontal rods only, that is, beams in which the w

tress in a single reinforcing-member. Fixing the ALLOWA
6 000 lb per sq in, the spacing of web-members is expr
rmulas, when A is the cross-section of a web-member:

$$s = 16\,000\ Al/V$$

$$s = 16\,000\ Al/0.7V$$

ining the length of horizontals necessary to properly
sses, the same method may be employed as for plate

remainder of the bar being carried up as an inclined member and carried ov the top of the supports in continuous beams. The rods remaining at any poi at the bottom or top must be of sufficient sectional area to carry the direct tensi beyond this point. There must also be a sufficient length beyond this point prevent slipping. Web-members must be so spaced that there will be a reinforc ment intersecting every 45° line of rupture below the neutral axis. The Ne York City Code prescribes that the spacing of the web-members should n exceed three fourths of the depth of the beam in that portion where the we stresses exceed the allowable value for shear in concrete. Sufficient BON STRENGTH of web-reinforcement should always be provided in the COMPRESSIO SIDE of the beam. In SIMPLE BEAMS, that is, beams resting on two supports, t ends of the bars should preferably be bent into hooks. Where bent up throu large angles, web-members should extend horizontally along the upper part o beam for some distance.

Attached Shear-Members. Stirrups need not be firmly attached to the te sional reinforcement; but the allowable BOND-STRESSES and SHEARING-STRESS in the concrete must not be exceeded in transmitting the stresses between stirru and longitudinal rods. The stirrups and inclined members must also devel sufficient BOND-STRESSES to transmit the entire stresses for which they are d signed, and they must sometimes be supplemented with anchorages in the co pression-side of the beam. It is, perhaps, better to have them attached, they will certainly assist in anchoring the tensional reinforcement. Differe forms of stirrups and methods of attachment are used. In the Kahn syste (Fig. 11) the stirrups form a part of the tensional reinforcement. The U for either upright or inverted, is a very common form of stirrup, and may be a r of either round or square cross-section, or a flat strap as shown in Figs. 10 and 1 The Hennebique system employs both inclined rods and vertical stirrups. some cases, when the slabs and beams are constructed together, the slab-rei forcement is carried through the upper ends of the stirrups.

The Bond between Steel and Concrete. The BOND between the steel tension and the concrete must not exceed the safe working value. If the bo is not sufficient, the rod will slip. Tension-rods must, therefore, never be t large to develop sufficient BOND-STRENGTH to transmit the stresses. Wh bent-up bars are employed, the BOND-STRESSES in places, in both the straig and bent bars, will be higher than if all bars are straight. In cantilever bea the ends of the bars at the supports are fully stressed and the bars must carried into the supports and anchored to develop this stress. In anchori bars, an additional length must always be provided above that required, on t assumption of UNIFORM BOND-STRESSES. Wherever possible, adequate bo strength should be provided throughout the length of the bar in preference end-anchorage. Between plain bars and concrete the BOND-STRENGTH may assumed to be 4% of the COMPRESSIVE STRENGTH of the concrete.

The Breadth of a Reinforced-Concrete Beam of Rectangular Cros Section. The breadth of a rectangular beam, and of the stem of a T bea as already indicated, is generally dependent upon the amount of reinforceme necessary, and it is equal to the sum of the diameters of the tension-rods, t required spaces between them, and the amount of concrete outside of the ro needed to resist the shearing-stresses and to protect the steel. When no stirru are used in a beam it is necessary, also, to make the width of the concrete su cient to resist the horizontal shearing-stresses. This width should be at le equal to the sum of the perimeters of the tensional reinforcing-rods. T amount of concrete to be provided below the steel is fixed by the requireme for proper protection of the steel against fire and corrosion. (Pages 955–9

Compression-Rods in Beams and Girders. Steel reinforcement in the rm of rods is sometimes provided ABOVE THE NEUTRAL AXIS in beams and irders for the purpose of providing additional COMPRESSIVE STRENGTH where here is not sufficient concrete above the neutral axis to resist the total compression. If steel reinforcement is to be used for this purpose, the steel should e placed as high as possible, and the allowable unit compression in the steel mited to the actual compression in the concrete at that point multiplied by e ratio of the modulus of elasticity of the steel to that of the concrete, as in e case of columns with vertical reinforcement. The use of STEEL IN COMPRESSION in beams and girders, however, is not recommended, since at best it very uneconomical and the steel has a tendency to buckle and disrupt the oncrete.

Reinforced-Concrete Columns. Reinforced-concrete columns are of three neral types: (1) concrete with VERTICAL REINFORCEMENT near the outer rfaces; (2) concrete wrapped with SPIRALLY-WOUND WIRE or with metal ands; (3) concrete with a METAL CORE.

Lengths of Columns. The lengths of reinforced-concrete columns are variously limited by different authorities as follows, the figures being in each case e RATIO OF THE LENGTH to the LEAST LATERAL DIMENSION:

New York	15
Chicago	12
Philadelphia	15
St. Louis	15
Cleveland	15
Baltimore	16
San Francisco	15
Buffalo	15
Detroit	15

New York limits, also, the least side or diameter to 12 in, and San Francisco 10 in.

Vertically-Reinforced Columns. In determining the strength of columns th VERTICAL REINFORCEMENT, the steel is assumed to carry a load per square ch equal to the working load per square inch on the concrete times the ratio of e moduli of elasticity of the steel and concrete. The allowable stresses, ratio of oduli, etc., are given in Table II, page 912. For example, in New York a load 500 lb per sq in is allowed on the concrete, and 15 times 500, or 7500 lb per in on the steel, 15 being the ratio of the moduli, as fixed by the regulations, 1:2:4 concrete and steel. Not less than ½% nor more than 4% of vertical inforcement should be used in reinforced-concrete columns. The reinforcing-ds should be tied together horizontally at intervals of not more than the least e or diameter of the column. This prevents, to a great extent, the buckling the reinforcement under load and the consequent splitting of the concrete. e VERTICAL REINFORCEMENT, in order to serve its purpose of taking up the nding in the column, should be placed as near the outer surfaces of the column possible, consistent with proper protection of the steel. (See page 958.) If nsion is possible in the longitudinal steel, due to bending, the bars must be iced to resist the stress. In the DISPOSITION OF THE STEEL the same precautions are necessary as in the case of beams, in order to avoid a too close acing of the reinforcing-pieces or an excess of reinforcing-material. (See e 937.) As the concrete in columns is generally poured into the molds at e extreme top, it is particularly important to keep the interior free from erlacing steel across the column. In columns in which the steel is assumed

to furnish part of the COMPRESSIVE STRENGTH, it should be made continuo from the columns of one story into those of the stories below. The ro extending from one column may be connected with those above or below b means of pipe-sleeves.

Laterally-Reinforced Columns. Tests made on HOOPED CONCRETE COLUM at the University of Illinois in 1907, at the Watertown Arsenal in 1906, and the University of Wisconsin in 1906 and 1907, show that the ultimate compressi strength of such columns is increased from 500 to 1 000 lb per sq in for ea percentage of hooping employed. The increase of strength is due to the LATER COMPRESSIVE STRESSES developed by the restraining action of the hoops bands at right-angles to the direct compressive stresses. Below the limit elasticity, however, very little stress is developed in the lateral steel, and t tests show that at an early stage, the deformation or shortening of the colu is equal to that of plain concrete. With further loading, the laterals begin work and prevent failure, thus increasing the so-called TOUGHNESS of the colu and the ultimate compressive or breaking strength. This effect has been v riously allowed for by considering the hooping-metal equivalent to and repla by imaginary longitudinals. Considère and other investigators have shown t the hooping is equivalent to 2.4 times as much longitudinal steel. It is gen ally conceded that hooping permits of a somewhat higher unit stress in the c crete. The New York City Building Code permits an axial compression in s columns, having not less than ½% nor more than 2% of hoops or spirals spa not farther apart than one sixth the diameter of the enclosed column nor m than 3 in, and having not less than 1% nor more than 4% of vertical reinfo ment, not to exceed 500 lb per sq in on the concrete within the hoops or spi nor 7 500 lb per sq in on the vertical reinforcement, plus a load per square i on the effective area of the concrete equal to twice the percentage of late reinforcement multiplied by the permissible tensile stress in the lateral reinfo ment. St. Louis and Cleveland permit 2.4 times the volume of hooping to considered as longitudinal reinforcement; Chicago 2.5 times; and Cincinnati times.

New York Requirements Expressed by Formulas. The safe lo for reinforced-concrete columns according to the requirements of the N York Building Code may be determined by the following formulas, in wh

W = total safe load, in pounds;

A_c = the effective cross-sectional area of concrete, in square inches, which the case of columns with longitudinal reinforcement only, may taken as the entire area, and in the case of hooped columns is limi to the area within the hoops;

A_s = the cross-sectional area of the longitudinal steel, in square inches;

p = percentage of lateral reinforcement (hooping), that is, the volume of hooping divided by the volume of the concrete enclosed within hooping, for each unit length of column;

S_c = allowable compressive stress in the concrete, in pounds per square i which is taken at 500 for 1 : 2 : 4 concrete, and at 600 for 1 : 1½ concrete;

S_s = allowable compressive stress in the steel, in pounds per square i which is taken at 7500 when 1 : 2 : 4 concrete is used, and at when 1 : 1½ : 3 concrete is used;

S_h = allowable tensile stress in the hooping steel, in pounds per square i which may be taken at 35% of the elastic limit, but not more 20 000.

longitudinal reinforcement only,

$$W = A_c S_c + A_s S_s$$

steel must not be less than 1½%, nor more than 4% of the and the reinforcement must be secured against displacement paced not farther apart than 15 diameters of the vertical 12 in.

is the safe carrying capacity of a 12-in square column of inforced in each corner with ⅞-in square bars?

rea of the concrete may be taken at $12 \times 12 = 144$ sq in. ias a sectional area of 0.7656 sq in. The area of the steel i sq in, a little over 2% reinforcement. The allowable and steel are 500 and 7500 lb per sq in, respectively. Hence

$$14 \times 500 + 3.06 \times 7\,500 = 94\,950 \text{ lb} = 47\tfrac{1}{2} \text{ tons}$$

ns,

$$W = A_c S_c + A_s S_s + 2\,p\,A_c S_h$$

inforcement not less than 1%, nor more than 4%, and n ½%, nor more than 2%, the hooping being spaced not ne sixth of the diameter of the enclosed column, and at

ine the maximum load that should be placed on a 24-in 1½ : 3 concrete, with spiral hooping of 5⁄16-in cold-drawn pitch, and reinforced longitudinally with six 1-in round just inside the hooping, and fastened to it, the concrete ide the hooping.

ective sectional area of the concrete has a diameter of re $20 \times 20 \times 0.7854 = 314.16$ sq in. For an inch in height, the concrete is 314.16 cu in. The area of a 1-in round The area of longitudinal steel is $6 \times 0.7854 = 4.71$ sq in, ross-sectional area of 5⁄16-in wire is 0.0767 sq in. The wire is 62.75 in, and as the turn is made in a height of its for an inch of height of the column is $\frac{1}{3} \times 62.75 \times 0.0767$ ½%. The working stress per square inch for the con- longitudinal steel 7 200 lb, and for the hooping 20 000 lb.

$$600) + (4.71 \times 7\,200) + (2 \times 0.005 \times 314.16 \times 20\,000)$$
$$= 285\,240 \text{ lb, or } 142.6 \text{ tons}$$

Reinforcement. At the top or base of the columns in ping should be made to continue through the floor-con- tain conditions, when the floor-construction is practically mns, thus affording good lateral support, equal to the better to omit the wrapping and avoid the possible com- orcement from column, girder, and floor-construction and ng of the bond of the concrete. The materials used for the teel wire or steel bands. When wire is used it is spirally s through the full length of the column. The ends of the he column and turned down to such an extent that when poured and set, there will be sufficient anchorage to resist

the tension in the wrapping due to the outward pressure of the concrete. W metal bands are used, as in the Cummings system, care must be taken to m the riveted joints in the bands as strong as the bands themselves. A for wrapping that has the merits of rapidity and ease of erection is shown in columns used in the Bush Terminal Warehouse, Borough of Brooklyn, York City, described on page 958.

Fig. 20. Concrete Column with Steel Core

Metal-Core Columns. The object of this type of column is to pro construction for tall or heavily loaded buildings that will have the ne strength and yet not encroach too seriously on the floor-space. For th of column some engineers advocate placing a steel core through the axi concrete, the steel taking the bulk of, if not all of, the load.* "A ration of design is to determine the strength of the steel column by the use of the c formula for the proper l/r of the column and to consider the concrete of th

* Trans. Am. Soc. C. E., Vol. XIV, Part E, page 556.

› have a stress-value proportional to the strength of plain con-

n H. Burr designed a column (Fig. 20) for the McGraw Building, New . The steel core has sufficient strength as a column, independent of ete, to carry the entire dead load coming upon it, the stresses in the ; in no case greater than those allowed on steel columns under the Building Code, considering the ratio of length to radius of gyration. re, those stresses were not allowed to exceed 9 000 lb per sq in in any : live loads were provided for by placing enough concrete within the work to prevent the stress on the concrete from exceeding 750 lb This is one twelfth of the maximum allowable load on the steel. te outside of the steel was considered only as a protection against fire ion. Columns of this type should be designed with caution. The ould not be relied upon to tie the steel units together or to transmit m one unit to another. The units should be tied together by tie- attice-bars in conformity with the standard practice for structural For high percentages of steel, the concrete will develop low unit d caution should, therefore, be used in placing dependence upon the

ixtures of Concrete. Increasing the proportion of cement in a reases the ultimate strength of the concrete proportionally and is designing columns with smaller cross-sectional area. The increased : strength is also accompanied by a higher modulus of elasticity. e, the employment of a rich mixture also permits of higher propor- ses in the steel and consequently a more economical design. The sses in a monolithic member, however, may be considerably com- the excessive shrinkage of rich mixtures, which have a tendency to : New York Building Code provides that "in concrete columns the on the concrete may be increased twenty per cent when the fine and gates are carefully selected and the proportion of cement to total increased to one part of cement to not more than four and one-half egate, fine and coarse, either in the proportion of one part of cement, -half parts of fine aggregate, and three parts of coarse aggregate, oportion as will secure the maximum density. In such cases, how- npressive stress in the vertical steel shall not exceed seven thousand l pounds per square inch."

gs Lateral Reinforcement. Robert A. Cummings of Pittsburgh, Welding Company), following a European practice, has applied a einforcing compression-members by placing horizontal wire spirals ight-angles to the main compressive stresses. This practice is based y that the failure of a concrete prism will take place along lines e direction of the applied load. The method has been very success- ing the heads of precast concrete piles, driven by hammer.

Columns. When a building for any reason need not be treated of structure, space and time may be saved by using CAST-IRON or NS. In such cases the column-connections must be designed with ings for the concrete construction and so that there will be a CON- hat construction; for the great advantage in reinforced-concrete lies in its MONOLITHIC character. When cast-iron columns are ds of the columns may be cast with openings through which the

* University of Illinois Bulletin, No. 56, 1912.
† Proc. Am. Soc. C. E., Feb., 1913, page 153.

reinforcement may pass from one side to the other. Fig. 21 shows how this been done in a building at Gay and Christopher Streets, New York City w out impairing the strength of the columns at the connections.

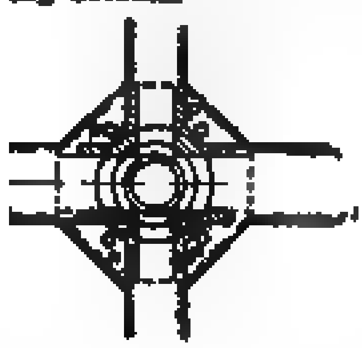

Fig. 21. Connections for Cast-iron Columns and Reinforced-concrete Constructi

Steel Columns. In STEEL COLUMNS it is simpler to provide connec between the reinforcing-rods and the steel shapes of the columns. When reinforcement does not go through the columns, some rods should be pl outside of them to tie as much as possible the concrete on one side to tha the other.

Eccentric Loads. Bending stresses due to LATERAL and ECCENTRIC L must be computed so that the combined direct and bending stress does exceed the allowable maximum stress for axial compression. Formulas eccentric loading on columns are given in Chapter XIV, pages 453 and 48

Concrete Walls. If not reinforced, concrete walls are generally requir be of the same thickness, for given conditions, as brick walls. Under such cumstances they are not as economical as brick walls. If reinforced and us bearing-walls, they can be reduced to about two thirds the thickness of walls, provided, however, that the load on the concrete does not exceed the load per square inch permitted on reinforced columns. The ratio of unsupp height to thickness should not exceed that fixed for columns. For span walls, supported entirely on girders, the minimum thickness should be Such walls should be reinforced with not less than ½ lb of steel per square of wall, in the form of rods placed vertically and, less frequently, horizon

Reinforced-Concrete Footings. (See, also, pages 186, 225, and 226.) principles underlying the design and construction of reinforced-concrete foo are the same as those applied to other types of footings. In wall, pier, or col footings, the overhang or off-set must be considered as an INVERTED CANTIL loaded uniformly with a load per square foot equal to the load per square imposed on the underlying soil. The reinforcing-rods will then necessaril placed near the lower surface of the footing and the size and number determ as shown on pages 937, 938, and 979. A detail often overlooked in reinforced

ngs is the tendency to SHEAR at the edge of the wall, pier, or column . When footings would otherwise become very ECCENTRIC, cantilevers resorted to, the same as for steel construction. (See pages 165 to 169, o 982.) The maximum bending moments are determined and the signed as described on pages 925 to 932, and 978 to 982. Steel in hould be protected by at least 3 in of concrete.

ry of Reinforced-Concrete Footings. Great economy over steel-other types of footings may often be effected by the use of REIN-NCRETE FOOTINGS. The cost of the latter type will vary from 20 to e cost of a corresponding STEEL-GRILLAGE FOOTING. This difference counted for. The amount of excavation for the reinforced footing is much less than for the steel grillage. A smaller amount of concrete d this concrete is considered in the calculations for strength; whereas l grillage, the concrete is chiefly provided for incasing and protecting The amount of steel is much less, being used only to supply the ten-tance of the construction, the compressive strength being supplied ch cheaper material, concrete. Incidentally, the protection of the reinforced footing is generally more certain than in the steel-grillage

e Piles. Concrete piles are discussed in Chapter II, pages 196 to me of the types are there described.

ions in Reinforced-Concrete Construction. Much good judgment played and must be exercised in the design of the details in these . The great value of reinforced-concrete construction over other e possibility of securing great RIGIDITY. This can only be attained esult is as nearly MONOLITHIC as possible. We than have mass to ration and this advantage, in the case of workshops or factories in e is machinery, is readily seen. The reinforced-concrete buildings hrough the severe San Francisco earthquake in May, 1906, in good were those in which attention had been given to the details and con-To secure a monolithic character requires CONTINUITY not only in the it also in the reinforcement. This often means that there is a net-l at the connections. If this is carried to excess, the BOND and CON-the concrete is apt to be broken, even when the spaces between the are thoroughly filled. But when there is such a network of steel ike a sieve and the spaces are not readily filled. For this reason it e a richer mixture at the columns and to keep the aggregate as small The connections of floor system to columns are particularly trouble-respect, and partly for this reason and partly to insure rigidity, uld be provided under the girders at the columns, with metal rein-ear the inclined surfaces of these brackets.

ed-Concrete Stairs.* Some of the most interesting work that has e reinforced concrete has been the construction of stairs. The rein-eing in the form of comparatively small, limber bars, can be adapted y shape for which molds can be constructed, and when a wet, rich h small aggregate is used, little or no difficulty need be experienced As an example of such work, the stairs in the residence of G. W. in New York City, may be cited. When these stairs were five test of their strength was made, without distress, by dropping a ur bags of cement, weighing about 380 lb, from the floor above to

* See, also, pages 900 and 983.

the intermediate platform, a distance of 11 ft. No injurious effects were ticed.*

4. Types of Reinforced-Concrete Construction †

Mill-Construction. In localities where the cost of labor is high and wl the conditions cause more or less congestion, it is probably more economica use brick instead of concrete for the walls. In such cases the type of const tion is similar to ordinary MILL-CONSTRUCTION. Provision must be made to chor the beams and girders, and this can be done by bending the ends of reinforcing-rods so that they will extend horizontally into the walls on each s

Skeleton Construction. The SKELETON TYPE of construction seems to the form best adapted to reinforced concrete. A framework of columns, gird beams, and flooring is built, as in steel construction, the wall-girders and colum of course, being designed to carry the weights of the outside walls as wel that part of the floor-loads and live loads which comes on them. The work this type of construction, can generally progress more steadily than in the m CONSTRUCTION since the concrete work need not be stopped at any time to for the brickwork to be carried up, if brick is used for the walls. In the SKE TON CONSTRUCTION any type of outside wall may be used; brick, concrete, etc. In some cases the panels are simply filled in with brickwork, 8 or 1 thick, leaving the concrete columns and girders showing between the b panels. For walls situated on property-lines where adjoining buildings are li to be erected, this is not objectionable. If the wall remains exposed and a g appearance is a consideration, the columns and girders can be treated archi turally to set off the brickwork; or the brickwork may be continued as a fa over the outside of the columns and girders. This was done in some of the B Terminal Warehouses, Borough of Brooklyn, New York City.‡ To thoroug secure this brick facing, galvanized anchors were placed in the concrete colu and girders as they were erected, projecting sufficiently to bond into the br joints. In using concrete for the panels the sides of the columns are cast w pockets, grooves, or recesses to receive the panels, which, as in the case of bri work, are most satisfactorily and most economically built after the remova the molds from the skeleton frame. In the Marlborough-Blenheim Hotel Atlantic City, N. J., the panels are filled in with hard-burned terra-cotta t and a stucco applied on the outside. This makes a comparatively light c struction and affords good insulation. The particular advantage in the SKE TON TYPE of construction, especially for workshops and factories, is the possibi of large window-areas affording light and ventilation.

System M. A type of construction known as System M has been develo by the Standard Concrete Steel Company of New York City (Fig. 22). It c sists of a light steel skeleton frame designed to carry the dead load of the en structure, except that the columns are designed to carry the gross loads. T structure is incased in concrete, making ultimately a reinforced-concrete constr tion.§ Its advantage consists in its adaptation to the erection and inspectio the steel reinforcement before even the centers or molds are placed in positi Under congested conditions, such as prevail in large cities, it is a rapid form

* For a detailed description, see Cement, Jan., 1904, and Engineering Record, Dec, 1903. For other examples of stair-construction, see Engineering News, June 30, 19

† See, also, Chapter XXV.

metal used. Furthermore such shapes must necessarily be subjected
ending, which tends to break the bond between concrete and steel.
ab Construction.* In this form of construction beams and girders
ated almost completely, if not entirely, and the slab is made to rest
the columns; the tops of the columns are enlarged into extended caps.
m of construction employs a shallower floor construction than is ordi-
inable. The floor-centering, too, for purposes of erection, is somewhat
pecially in those forms of slabs in which the lower surface is all in one
e slab may be of uniform thickness between the edges of the column-
a portion of it, symmetrical about the columns, may be thickened to
UMN-DROP, or the slab may be thickened to form a band or shallow
een columns, with a paneled ceiling at the center of the panel.
the method of reinforcing the slab and columns, a number of systems
developed which may be divided into four general classes: (1) the
SYSTEM; (2) the FOUR-WAY SYSTEM; (3) the THREE-WAY SYSTEM; and
CUMFERENTIAL SYSTEM. In the TWO-WAY SYSTEM, the reinforcement
direct bands between the columns in both directions, with an interior
wo-way rectangular bands on the remaining panel-area at the center.
R-WAY SYSTEM, the reinforcement is placed in two direct bands in the
gular directions, and in two diagonal bands which cross the panel
between columns. In the THREE-WAY SYSTEM the reinforcement
bands directly connecting the columns and passing over the column-
the CIRCUMFERENTIAL SYSTEM, circumferential reinforcement is
nd the columns, with bars radiating from the column-centers. Con-
s of reinforcement are also placed at the center of the sides joining
ters, which overlap the circumferential reinforcement at the columns,
nter of the panel is reinforced in a similar manner. Some of the
veloped are modifications of the above or a combination of two or more
ral types described. The principles of design are based on empirical
termined by extensometer tests made on completed buildings.
ystem. This is a TWO-WAY SYSTEM developed by the Condron
Chicago, Ill. It is constructed either with a slab of uniform thick-
a drop-panel, or with a paneled ceiling. Each panel of the slab is

* See, also, Girderless Floors, Chapter XXV, page 993.

divided into two sets of strips, called the MAIN-SLAB STRIPS and the MID-
STRIPS, which are designed as flat, shallow beams.

Corr-Plate System. This type of construction has been developed an stalled by the Corrugated Bar Company, Buffalo, N. Y. The constructi similar to other TWO-WAY SYSTEMS and is installed either with or without d The reinforcement is distributed across the entire slab, with varying spaci resist the stresses determined experimentally.

Mushroom System. The MUSHROOM SYSTEM, invented by C. A. P. Tu Minneapolis, Minn., is one of the earliest of the flat-slab constructions. striking and essential feature which gives this system its name is the gra spreading out of the column at the top to form a cap, the diameter of whi seven sixteenths of the sum of the distances between columns in the directi the sides of the slab. The longitudinal column-reinforcement is bent to fo the curved outer surface of the cap, and the cap is reinforced both radially circumferentially. The slab-reinforcement is placed at the top of the slab the columns and allowed to sag to a catenary curve with the low point nea bottom of the slab at the middle of the span. The thickness of the slab v from 1/35 to 1/40 of the shorter distance between the column-centering. Th essentially a FOUR-WAY SYSTEM with the added features described above.

The Cantilever Flat Slab, designed by the Concrete Products Comp Chicago, Ill., is another type of FOUR-WAY SYSTEM. It differs from the on scribed in the preceding paragraph mainly in the construction of the column The column-bars are not bent to the shape of the cap but continue up stra The horizontal cap-reinforcement is provided by a shop-made frame of r bars, held together by a Diamond Bar which is intended to resist the cir ferential stresses. The diameter of the cap is about 3/10 the span and the t ness of the slab about 1/35 the span. Whenever necessary to provide for l shearing-stresses and bending-stresses around the column, the slab is incre in thickness at that point, forming, in appearance, an extended cap at column-head. Later extensometer tests have proved the use of radial with rings around the column-heads to be inefficient, and they therefore been abandoned.

Three-Way System. This system was invented and patented by Davi Morrow, Cleveland, Ohio. The columns are located at the apexes of equila triangles, making equal the bands of steel between the columns. The reinf ment over the columns is placed in three instead of the four layers of the f WAY SYSTEMS. Flaring circular caps, with hexagonal or circular drops, are vided over the columns.

S. M. I. System. This system was invented and patented by Edw Smulski, and is controlled by the S. M. I. Engineering Company, Boston, M Circumferential and radial reinforcement is placed in both the top and bot of the slab, with trussed bars extending both rectangularly and diagonally tween the columns (Fig. 23). The radial bars are provided with a semicirc hook to transfer the stresses into the concrete by bond, and to engage the ri reinforcement in the center of the panel. To prevent cracking on the top o slab between columns, additional short, straight bars are sometimes used.

Patents for Flat-Slab Construction. In 1901 and 1902 patents granted to O. W. Norcross, covering girderless floor-construction reinforced bands of wire netting extending from column to column. Application fo original C. A. P. Turner patents was made in 1905. In 1915 the United St Courts held that the Norcross patents covering girderless floors were fu mental, and that bands of bars were, to all intents and purposes, the sam

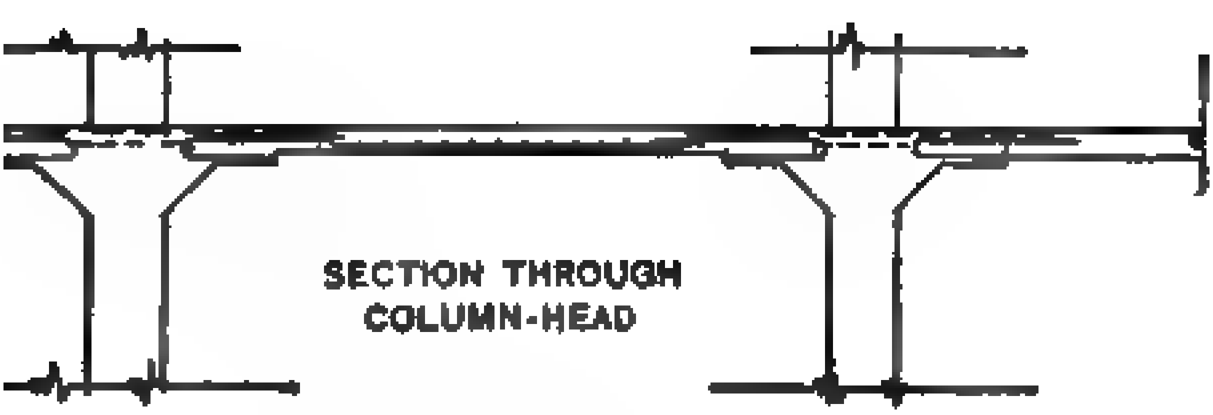

Fig. 23. S. M. I. Flat-slab System

e netting. It would seem, therefore, that any system of floor-con- pending upon bands of bars running either diagonally or crosswise to column constitutes an infringement of the Norcross patents. promoters of flat-slab construction in the United States are now er the Norcross patents; but several other United States patents anted covering special methods of construction and reinforcement.

tion Hollow-Tile and Reinforced-Concrete Construction. In nimize the cost of centering, the floor-construction shown in Fig. 24 vised. It consists of a series of reinforced-concrete beams with between them of the width of the hollow-tile blocks. In erection, a

flat centering is used, which, however, need not even be continuous. Planks few inches wider than the concrete beams, are placed under the spaces to be fil by the beams, and the tiles are laid in rows and supported along their edges the planks, thus forming the sides of the molds for the beams. The reinfor ment is placed and the concrete poured, with or without floor-plates, as the nec sities of the case may require. Care must be taken in pouring the concr

Fig. 24. The Combination Tile and Reinforced-concrete System

that the tiles are not displaced sidewise. The tiles should fit closely at th joints, otherwise the finer particles of the concrete are liable to flow into the either making the concrete porous or requiring more cement and sand than necessary. This form of construction, besides being economical in centeri offers the advantages of a flat ceiling without the application of lath and, in ro construction particularly, of freedom from condensation.

The Floretyle Systems. A floor-construction similar to the hollow-t construction just described has been devised by the Truscon Steel Compan Youngstown, Ohio, in which forms of corrugated sheet steel, called FLORETYLE replace the hollow tiles. The Floretyles are furnished in lengths of 28½ and in, and in depths of 6, 8, 10, and 12 in. The width at the base is 20¼ in, with t sides tapering at an angle of 7° 30′. They are furnished in two types, either w serrated edges for use with the company's Hy-rib lath for ceilings, or with strai edges for use where paneled ceilings are required. Other makes of metal for used in the construction of reinforced-concrete floors are the G F STEEL TILES of t General Fireproofing Company, Youngstown, Ohio, and the WISCOFORMS of t Witherow Steel Company, Pittsburgh, Pa. Besides a reduction in weight finished floors, the additional advantages in the use of these steel tiles or for over the terra-cotta fillers are: Greater economy in centering, larger coveri capacity, less bulk in shipment because the forms can be nested, and less dam

on of water from the concrete and of the flooring-out of the cement at A concrete floor of O F STEEL TILES, spaced so as to make 4-in con-s, 24 in on centers, and having 2 in of concrete above the tiles, with- is said to have the properties shown in the table on page 952,) the depth of tiles used.

y Tile Systems. Similar in general principle but using reinforce- directions, at right-angles with one another, is the COMBINED HOL-ID-CONCRETE FLOOR, controlled by the Burchartz Fireproofing Com- New York City, under the Burchartz patents (Fig. 25). This system ra-cotta blocks, channels, and soffits, providing uniform flat ceilings ster can be applied without the use of metal lath. In this case the ilated as a slab supported on four sides. (See page 936.) The con- :vented from running into the hollow spaces of the tile by the use -cotta channels as shown.

ies. In the FLOREDOME-CONSTRUCTION, put on the market by the el Company, Youngstown, Ohio, the tile spacing-blocks of the TWO- STEM are replaced by rectangular dome-shaped steel forms with the pen. Lightness in floor-weight, ease and rapidity of installation, and s are the advantages claimed. The ceiling-treatment in this con- similar to that in the Floretyle system. The base of the domes is .5 in square; the depth varies, being 6, 8, 10, or 12 in.

of Combination Systems. While the tiles may under favorable ld to the strength of the COMBINED FLOOR-CONSTRUCTION, the chances tory workmanship are too great to consider them in the calculations In the floors reinforced in one direction, the construction should s a series of either rectangular beams, or T beams, as the concrete :r to or above the top face of the tiles. The TWO-WAY REINFORCED N should be treated as if it consisted of a slab supported on four . series of intersecting rectangular beams, or T beams. If the con- o be treated as a series of T beams or as a slab, the concrete should t 2½ in above the top surface of the slab and the tiles or fillers should % of the volume of the construction.

y-molded Construction. The UNIT OR SEPARATELY-MOLDED CON-nsists of precast reinforced-concrete members, columns, girders, bs, either molded at the site of the building, or made at the factory to the site ready for use. The various members are swung into h the same manner as steel is erected, and fitted together in the interlocking reinforcement and poured grouting. Great economy this method of erection on account of the saving of forms. Maxi- y, however, cannot be obtained on a building operation of less than as economy is obtained by the greater use of the forms and the : the erecting-crews with the particular type of building. But onditions, economy can also be shown on an operation involving 000 sq ft. The advantages of this construction are said to be: nber of uses possible of one set of forms, especially on a large opera- ll number of men required, due to the extensive use of locomotive- trucks, derricks, etc.; the ease with which the units may be in- being poured and before entering the building; and the fact that all kes place before the units enter the structure, thus eliminating cks in the building. The disadvantage of such a system, however, e in the lack of sufficient rigidity in tall, separately-molded unit All floor-members must be designed and cast as simple, NON-CON-TS, with the reinforcement left projecting at both ends to serve for

Fig. 25. Republic Two-way Tile-and-concrete System

tructure together. These junctures are made after the units are place, and supported by a pouring of rich concrete. For tall strucore feasible to erect a light structural-steel frame and employ the -units only. (See Chapter XXIII, page 854.) The saving in cost ticularly in low buildings, and more especially in one-story strucbuildings having been erected at a saving of from 10 to 20% over construction. Methods of interlocking the units and providing details are constantly being improved and a series of tests of the such connections is being carried on by the Unit Construction St. Louis, Mo. There are under construction, or already completed, igs of this type installed by the above company, including five-story · the National Lead Company, at St. Louis, Mo., Kansas City, ttsburgh, Pa.; a three-story building for the Ohio Cultivator Comeville, Ohio; five acres of car-barns at Philadelphia, Pa.; and approxteen-and-a-half acres of cotton-warehouses at Memphis, Tenn. ie Engineering Company of New York City has erected five-story buildings with its Unit system, in Boston, Mass.

'ire-Resistance of Reinforced-Concrete Construction

luctivity of Reinforced Concrete. Concrete is a poor conductor in this fact lies whatever virtue it has as a fire-proof material.† A made by Professor Woolson of Columbia University, New York orted at the 1907 meeting of the American Society for Testing Matethe following results:

all concrete mixtures when heated throughout to a temperature 500° F. will lose a large proportion of their strength and elasticity, fact must be well remembered in designing."

all concretes have a very low thermal conductivity, and therein known heat resisting properties."

as a result of this low thermal conductivity, two to two and one- concrete covering will protect reinforcing metal from injurious eriod of any ordinary conflagration (provided, of course, that the in place during the fire)."

reinforcing metal exposed to the fire will not convey by conducious amount of heat to the embedded portion."

the gravel concrete was not a reliable or safe fire-resisting aggre-

rength of Reinforced Concrete. If its NON-CONDUCTIVITY were olved in the fire-proof character of concrete, the minimum thickfor the protection of the steel could be easily determined. But of the concrete is more or less affected when exposed to extreme rt has been made to determine this effect and a summary § of the orted by Professor Woolson of Columbia University, New York in Tables XII and XIII.

Record, Vol. 60, page 643; Engineering News, Vol. 58, page 5; Proal Association of Cement Users, 1910, page 391.

remembered that in this and succeeding paragraphs on the fire-resisting ncrete, only such material as is used in reinforced concrete, is considered. nder concrete as a fire-proof material is discussed in Chapter XXIII,

News, Aug. 15, 1907, page 168.

oc. for Test. Mats., Vol. IV, page 433.

Fire Tests on Reinforced Concrete. The EFFECT OF FIRE on reinfor concrete has been studied in a number of tests made by the building authorit of New York City and Philadelphia, and in some of the conflagrations in t country, notably at San Francisco. The tests to which the sample full-s constructions have been subjected are similar to the test described in Chap XXIII, page 827.*

lusion, from a study of the tests in detail,* shows that to a depth
bout 1 in, the concrete is seriously impaired and easily washed off by a
applied to the surface. Any stone containing an appreciable per-
arbonate of lime will calcine and may cause failure. Where the con-
poorly designed, allowing an excessive deflection, the fine cracks
ete below the steel will open to such an extent as to permit the heat
metal reinforcements. When the reinforcement is such as to pro-
of weakness in the concrete there is liable to be a flaking off of the
l a consequent exposure of the metal.

ire Tests of Reinforced Concrete. The EARLIEST TEST of a re-
crete building in an actual fire occurred in 1902, in the four-story
e Pacific Coast Borax Company, at Bayonne, N. J. The roof of
was of wood, and with the contents of the building, was destroyed
The only damage suffered was a break in the top floor caused by
heavy tank that had been supported by the roof. At the same
ining building constructed with unprotected steel posts and beams
into a tangled mass of metal.

the Baltimore Fire. In the Baltimore fire there was but one
ncrete building of the three exposed to the fire, from which any fair
an be drawn. In one of the buildings, the concrete construction
destroyed, but this was probably due to the falling walls and the
her non-fire-proof parts. In a second building, the heavy rein-
ete floor of a banking-room came out practically unharmed; but it
osed to severe fire. The third structure was, however, exposed to
The contents of the building were destroyed and a large part of the
walls fell. The floors, five in number, were all of reinforced con-
ted on concrete columns, having replaced an old wooden-joist con-
test made after the fire showed that the floors were still strong
stain the loads for which they were designed, although the floor-
racked. The girders were cracked longitudinally near the lines of
ment, and the columns were spalled to such an extent as to expose
einforcement. It would have been difficult to restore the building
uld resist another such attack.†

the San Francisco Fire. The EFFECTS OF THE FIRE on concrete
in the conflagration immediately following the San Francisco earth-
6 are summed up in the following paragraph from the report of a
engineers that investigated the subject.

floors generally had hung ceilings, and, where thus protected, were
Where exposed, the concrete is in most cases destroyed, for instance,
Rialto, and the Aronson Buildings, and the Crocker Warehouse.

gs of wood invariably burned, adding to the destruction. Sleepers
y burned. Surfaces of cement mortar fared much better, the lino-
g remaining practically intact."‡

ng the report, Mr. A. L. A. Himmelwright, who made a personal
the ruins, concludes that reinforced concrete is inferior as a fire-
truction to any form of steel construction with concrete floors and

ed reports are on file in the Bureau of Buildings, Borough of Manhattan,

ewell in his report on this building draws a different conclusion. See
ews, March 24, 1904, page 276.

Soc. C. E., March, 1907, page 330.

concrete column and girder-protection, but superior to steel construction w terra-cotta floor and terra-cotta column and girder-protection. "Where method was used, a very slight attack of fire was generally sufficient to cause rupture of the concrete underneath the reinforcing-metal, so that it fell aw exposing the metal. There were comparatively few buildings, however, in wh this method of construction was used."*

Thickness of Concrete Required. From a study of the tests and fires referred to, the fair conclusions as to the AMOUNT OF PROTECTION against would seem to be as follows: (1) In all columns and in large and import girders, trusses, or other supports, at least 2 in of concrete outside of all reinfo ments; (2) in girders and beams and in slabs of long spans, about 1½ in of c crete outside of all reinforcements; (3) in stair-work, floor-slabs of short sp and walls and partitions, from ¾ to 1 in of concrete outside of all reinforcem The provisions recommended in the Building Code of the National Boar Fire Underwriters are: "Steel reinforcement shall have a minimum p tection of concrete on all sides as follows: In columns and girders, 2 inc in beams and walls, 1½ in; and in floor slabs, 1 inch. The steel in footings walls and columns shall have a minimum protection of 4 inches of concre

"The minimum thickness of concrete surrounding and reinforcing meml one-quarter inch or less in diameter shall be one inch; and for members bea than one-quarter inch the minimum thickness of protecting concrete shal four diameters taking that diameter, in the event of bars of other than circ cross-section, which lies in the direction in which the thickness of the conc is measured; but no protecting concrete need be more than four inches t for bars of any size; and provided, further, that all columns and girders of r forced concrete shall have at least one inch of material on all exposed surf over and above that required for structural purposes; and all beams and f slabs shall have at least three-quarters inch of such surplus material for fire sisting purposes."

Other Forms of Protection for Reinforced Concrete. Because of effects produced by fire on reinforced concrete, as above described, and difficulty of restoring the construction where so affected, various suggesti have been made to protect the concrete construction with other materials. account of its excellent fire-resisting qualities (see page 817), CINDER CONCR naturally suggests itself. This material is out of the question where stren is required. But its use may be combined with that of STONE CONCRETE, placing a sufficient thickness for protective purposes on the outside of the r forcements in columns, below the neutral axis in beams and girders,† and on under surface of floor-slabs. Difficulties are likely to be encountered, howe in placing two kinds of concrete in the same mold, but these difficulties not insurmountable. Careful inspection is required to see that the poo material is not put in place of the stronger. One kind of concrete should fol the other immediately in order to secure a bond between the two. This s gestion, serving at the same time another purpose, was satisfactorily applied the column-protection in the Bush Terminal Warehouses in the Borough Brooklyn, New York. The steel-wire wrapping for the columns was prepa in sections 2 ft in height. Metal lath with about a ½-in mesh was placed outs the wrapping and secured to it. This was then placed in a cylindrical woo mold 2 ft in height and with a diameter 4 in larger than the wrapping, t forming an inner side of the mold. The space between the wrapping and t wooden mold was then filled with cinder concrete. When set and the m

† Trans. Am. Soc. C. E., Vol. LVI, page 284.

he result was a hollow cylinder of cinder concrete, 2 in thick and 2 ith the column-wrapping attached to the inside These cylinders ne over the other in the building till the proper column-height was ch vertical rods as were wanted were put in, and the interior filled rete. Thus was produced a fire-proof, wrapped column, without d inconvenience of any column-molds in the building.

f fire-protection, advocated by the National Fire Proofing Company gh, Pa., is shown in Fig. 26. Here columns, beams, and girders are

Fig. 26. Tile Protection for Reinforced Concrete

ncased with HOLLOW-TILE BLOCKS. Being either laid in the molds hem, their rough and furrowed porous surfaces cause them to adhere e concrete They afford as efficient protection here as they do for s, and if destroyed the blocks can be replaced.

Aggregate on Fire-Resistance. Fire tests on full-size reinforced-lumns, conducted by Walter A. Hull at the Pittsburgh laboratories of f Standards, show that the nature of the aggregate plays an impor- resistance to fire. Silicious gravels appear to make unsatisfactory n the standpoint of fire-resistance. Limestone concretes are superior erials tested, including trap-rock and blast-furnace slags. Coatings aster, 1 in thick, and secured by a light, metal lath, protected the ffectively that the strength, after a four-hour fire test, was as much that of the unplastered columns after the test, and about 90% of olumn which had not been subjected to fire. Other forms of pro- ings investigated and proved effective, were a roofing-material of ent, sand, and asbestos, and cylindrical forms of cast gypsum, 3 in nd applied in a manner similar to those of cinder concrete described

ability of gravel concrete as fire-proof construction, was pointed out oolson as early as 1907* and appears to have been later confirmed

* Proc. Am. Soc. for Test. Mats., 1907.

by an actual fire in a reinforced-concrete warehouse at Far Rockaway, N. Y., 1916. From this the conclusion was drawn that "all concrete specificatio should contain a definite warning against the use of quartz gravel in concre liable to be exposed to high heat."*

6. Protection Against Corrosion in Reinforced-Concrete Constructio

Thickness of Reinforced Concrete. The THICKNESS OF CONCRETE requir for protection against fire has been found to be also ample for protection again CORROSION. It is well established that steel embedded in neat cement will n corrode. C. L. Norton of the Massachusetts Institute of Technology, Bosto Mass., draws the following conclusions from a series of experiments made 1902 and 1903.†

(1) Steel embedded in neat cement is secure against corrosion;

(2) Steel embedded in a dense concrete mixture is safe against corrosio

(3) To assure a thorough coating of the steel the concrete should be mixed we

(4) Porous concrete allows the admission of moisture and will not protect t steel thoroughly;

(5) A coating of rust is not a protection against further corrosion, as has be sometimes claimed.

In these experiments the steel was incased in concrete 1½ in thick on all side From this it would appear that

(6) The steel of reinforced concrete is secure against corrosion, provided it thoroughly embedded in concrete, and

(7) A slight coating of rust on the steel, where embedded, does no harn as the cement is strongly alkaline and will counteract the acidity of the ir oxide and prevent further corrosion.

"In practical design the most important question which arises is how f a concrete may be cracked (due to bending of beams) without exposing the ste to corrosive influences. In this respect it seems to the writer that the minu cracks which appear in the early states of the tests can have very little i fluence."‡ This means that within the safe working limits, there is no dang from corrosion on account of the fine cracks due to tension in beams and girde

Corrosion of Steel in Cinder Concrete. Cases are on record of serio CORROSION OF STEEL embedded in CINDER CONCRETE. In a report to the Stru tural Association of San Francisco, Cal.,§ the committee investigating the su ject states that in cinder concrete "the extent of the corrosion is great enou to seriously endanger the safety of the floors, and it is not probable that t floors would have supported their loads more than one to three years longer The committee recommended "that the Structural Association try to ame the present building law so as to exclude the use of cinder concrete in flo slabs or for fireproofing."

Mr. William H. Fox in his investigations ‖ on this same subject finds th "after about forty days' treatment, the specimens were broken, and the st carefully examined for corrosion. With but one exception, one or more of t three steel pieces in each specimen showed unmistakable signs of corrosi

concrete, if care is taken to provide a proper mixture and careful and thoroug workmanship.

7. Erection of Reinforced-Concrete Construction

Forms for Reinforced Concrete. For the erection of reinforced concret it is generally necessary, first, to construct MOLDS or CENTERINGS for the c umns, floors, etc. Wood is the material used for this purpose. Sheet-met centering has been used with questionable success and economy. In the sel tion of the wood for the molds a clean grade of dressed pine should be use It should be thick enough to resist warping and to resist deflection between su ports. It must be coated on its surface with soap or some other satisfacto

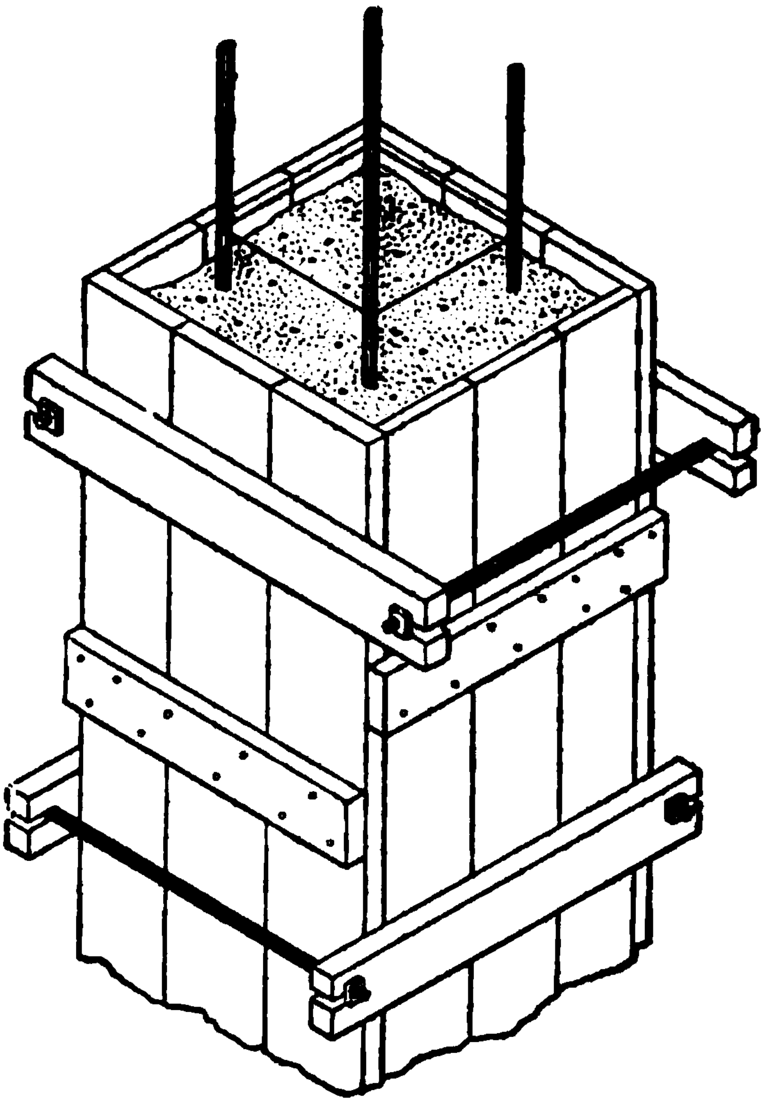

Fig. 27. Wooden Form for Reinforced-concrete Column

substance to prevent it from sticking to the concrete. The forms or molds m be erected carefully, the exact size of the proposed parts, and must be tru position and direction. For floor-molds, sufficient supports must be provid not only to carry safely the heavy wet concrete, but also such materials as liable to be placed on the floors up to the time when the concrete has set su ciently to carry such loads. The supports must have sufficient rigidity to prev deflection in the molds. The molds should be so constructed that they be easily removed when the concrete has set. Sharp corners should be avoi as much as possible, as the wood is liable to stick in them. Where there reentrant angles in the finished concrete-work, the molds should have bev edges, and at salient edges of the finished concrete-work, triangular strips sho be nailed in the corners of the molds to produce a beveled edge in the concr

: the spreading of the sides of the molds, cleats must be provided at intervals. In the case of beams and girders, these are gen- ed by nailing. In the case of columns and piers and often in walls, are so notched at the ends that long bolts with washers may be l them in place, as shown in Fig. 27. In removing the form the bolts l and the cleats and the rest of the form are ready to use again. In particularly in the construction of walls, the cleats are held in place ınning through the mold. These wires become embedded in the d in removing the molds they are cut and the portions in the con- owed to remain. The items of molds and centerings needed in the einforced-concrete buildings form a considerable part of the cost of ı. Economy in this respect can be affected in designing and planning he floor-panels throughout a building uniform in size and by repeat- s possible, such parts as piers, walls, etc. Successful attempts have › dispense with the erection of timber molds and centering by casting members of the construction on the ground and assembling and n in the same way that wood or steel columns, beams, and floors are ıd erected. (See page 953.)

Mixing. In all reinforced-concrete work the concrete should be ANICALLY. Satisfactory HAND-MIXING can be obtained and might be n very small jobs, where it would be uneconomical to set up a ER. But a much more uniform product will result from machine- nost types of mixers are mounted on wheels so as to be easily moved echanical mixers are either CONTINUOUS MIXERS or BATCH-MIXERS. ıous mixers the materials are fed sometimes by hand and sometimes , and the concrete issues continuously. The product, however, is he as uniform as that from the batch-mixer; for when the latter ınder constant supervision, whereas when the continuous mixer is hine is relied upon. Of the batch-mixers the ROTARY TYPE is the ıost general satisfaction. Among the efficient examples of this mentioned the mixers made by the Ransome Concrete Machinery ınellen, N. J., and the T. L. Smith Company, Chicago, Ill. They lifferent sizes and with capacities varying from about 10 to 60 cu yd

Concrete-Mixers. In CHARGING A CONCRETE-MIXER the materials , carefully measured, are dumped into the mixer and the machinery r completing a definite number of revolutions, sufficient to thor- ıe ingredients, the concrete is discharged into wheelbarrows or ıts for carrying it to the molds. Each batch should be completed is started. To obtain uniform results the number of revolutions on should be the same. It is not well to trust to the judgment of ırge of the machine, as to when the mixing has been thorough. ıstructed to count the revolutions each time. A good plan is to which rings when the fixed number of revolutions has been com- Code of the National Board of Fire Underwriters calls for "at ions," and the "speed of the mixer shall not exceed 20 revolutions

ete Mixture. The water is introduced during the process of ımount, also measured, should be such as to produce what is : MIXTURE, that is, a mixture that has the consistency of molasses ıdily flow around and thoroughly incase all steel to be embedded. ssary to vary the amount of water somewhat in placing a large te, as in walls, since the water generally works itself upward

through the successive layers. For TRANSPORTING THE CONCRETE from mixer to the mold, steel wheelbarrows, each holding about 2 cu ft, are gene employed. A larger vehicle, holding about 6 cu ft, is made by the Rans Concrete Machinery Company, Dunellen, N. J., and is found very economi in larger work. When the conditions will permit, concrete may also be dist uted by means of CHUTES, but care must be exercised to secure a consiste that will prevent the separation of the coarse aggregate from the mortar. transporting through the chutes may be done either by gravity or by c pressed air. Tests have shown that an excess of water tends to decrease strength of concrete, so that care must be taken not to use more water tha necessary to place the concrete properly.

Pouring the Concrete. Ideal conditions would obtain if the proce PLACING CONCRETE could be CONTINUOUS. This is not generally practic so it is important that the point at which work is stopped each day shall b selected and predetermined that the strength of the construction shall s least. In smaller buildings, with floor-areas not exceeding about 3 000 sq f should be possible to so arrange the progress of the work that each entire f construction may be placed in one day. In larger work it is necessary to off a certain area to be completed within the time of concreting for the Work should not leave off across important beams or girders, and the te rary stopping should be arranged for when the work is at the middle of or minor floor-beams. If any parts of floor-slabs are considered in the calc tions for the strength of the beams or girders, such parts must be concr at the same time and must be considered parts of such beams or gir Joints in columns should be made perpendicular to the axes of the colu and, as far as possible, at the lower side of girders. Columns should be allo to set for at least two hours before girders are cast on them, in order to pro for settlement and shrinkage.

Ramming the Concrete. As soon as the concrete has been poured int molds, and during the process of pouring, it should be continually RAMME secure complete filling of the molds, density in the finished product, and ough adhesion to the reinforcement. In wet concrete, such as is used for b ings, this ramming should be done with a flat steel spatula at the end of a ha long enough for comfortable manipulation. For column-work the hand lengthened out so as to reach to the bottom of the forms. Ordinary sp are sometimes employed, and where no special tools are provided, rammer sometimes made of 2 by 3-in scantlings, rounded off at the top end to a handle. Where a smooth surface is desired the spatula rammer shou used, particularly at the sides of the molds. The honeycombed appea that results from improper ramming is difficult to remedy afterward with surface of patches. After having been placed, the concrete should be damp by sprinkling it with a hose until it has thoroughly hardened. The ping of the forms with a hammer while the concrete is still plastic and bef has begun to set will cause it to flow more freely into place in intricate form around reinforcing-bars, especially when a dryer concrete, recommende recent investigators, is used. Tapping after it has started to set, however, to weaken the concrete.*

Removing the Forms from Reinforced Concrete. No fixed rule c given for the REMOVAL OF THE FORMS, as the time required for the setti concrete varies with the CONSISTENCY of the mixture, and the climatic and

* See "Effect of Vibrations, etc.," by Duff A. Abrams, Proc. Am. Concrete Vol. XV, 1919

Numerous failures of reinforced concrete have been attributed to ly removal of forms. In warm weather concrete will set more quickly d. The setting process may be somewhat accelerated after a day or noving the boards forming the sides of beams or girders and leaving ks on the underside and the props supporting them. In cold weather ible to warm the building during the setting process by means of s.

ish of Concrete Surfaces. The EXPOSED SURFACES of concrete ariously treated in attempts to produce a satisfactory appearance. pecial provision is made, the marks of the lumber used in the forms certain to show, and the lines of demarcation between successive clearly defined. To eliminate these lines, grooves are sometimes ormed, by tacking on the sides of the molds triangular or trapezoidal produce sunk joints in the wall, and give it an appearance resembling ne. The successive layers of concrete are in such cases stopped at so that the junction of the two layers is hidden. In some cases s purposely left rough and scratched like the scratch-coat in plaster- n stuccoed with a neat cement or a rich cement mortar. In this h there is always some danger that the stucco will flake off. The t comes from the mold, is sometimes hammer-dressed, or rather a special hammer. This hammer has an edge at right-angles to nd the edge is indented and made a series of points. A roughened produced which in time shows a uniform texture. Another method the forms as soon as the concrete is sufficiently hard and to rub the a plasterer's float or a block of carborundum, concrete, or stone, grout or fine sand with plenty of water between the float and the Brushing, also, may be resorted to, consisting in scrubbing the e still green, with a wire brush, and a mixture of one part of hydro- to six parts of water. A similar finish may be obtained by sand- the concrete has thoroughly hardened.

h of Reinforced-Concrete Floors. If the FLOOR-SURFACES are ered with a wooden flooring, a satisfactory finish may be obtained er the surface, before the concrete has had time to set thoroughly, sh from 1 to 1½ in thick, and troweling to make it smooth and finish is attempted after the concrete has set, the new and the old bably not bond; and there is always danger of flaking off unless the of considerable thickness.

Old and New Concrete. Various fluids and special cementitious e been put on the market for the purpose of BONDING NEW AND OLD RFACES. Whether or not these materials have any special merits, rally accepted that a good rich cement mortar will form sufficient two concrete surfaces, providing the surfaces are clean. If the PRESSIVE, the old surface of the concrete should be cleaned and surface may be roughened. Joints which are subject to TENSION ed with a 1 : 1½ or a 1 : 2 cement mortar before the new concrete ilding walls which must be water-tight, the structure should be THIC. And if it cannot, all dirt and LAITANCE should be removed, er of very rich mortar placed.

of Reinforced-Concrete Work. In all reinforced-concrete work ne importance to have competent and thorough INSPECTION or NCE. The inspector should be familiar with the nature and qual- ferent materials entering into the construction. He should have

a knowledge of the underlying principles of the design of reinforced-concre structures, so that he may realize the importance of carrying out all the detai and particularly of placing the reinforcement exactly as planned. He must l sufficiently alert and active to see that the work of the contractor is progressi properly; so that, for instance, work shall not have to be rebuilt because of err in the forms. The MATERIALS used in the construction, particularly the cemen should be tested as the work progresses. Cubes of the concrete as used shou be made up each day and at the end of seven days should be tested for com pression, and if necessary again at the age of twenty eight days. This recor will serve as a guide in the acceptance of the work, or in deciding on the nece sity for a load test of the finished structure. Under no circumstances, howeve should it replace or serve as an excuse to omit the testing of the cement up delivery or before acceptance. In addition to the details discussed in th chapter, details which require the attention of the inspector on the work, a fe others may be especially mentioned here:

(1) In JOINING NEW WORK with that which is already in, and which has beg to set, the surface must be thoroughly cleaned and wet. In stopping off work, is good practice where possible, to cast a groove in a surface that is to be join with another, so that when the work is afterward continued, a tongue-an groove junction is effected.

(2) All FORMS or MOLDS must be carefully cleaned out just before the concre is poured. The bottoms of the column-molds must be especially watched f this, as shavings, sawdust, and even blocks of wood are liable to fall into th unobserved. It is well to leave off a small piece of one side of the column-mo at the bottom, for purposes of observation and cleaning, and to close it up ju before pouring the concrete.

(3) Great care should be excerised in POURING and RAMMING concrete in de molds, such as for columns, walls, etc., in order to get the molds thorough filled at the bottom. In careless work it is not unusual to find in such pla very porous concrete, if not large pockets. This is particularly liable to occ when there is considerable reinforcing-steel in the construction.

(4) It should be remembered that concrete shrinks in setting. Hollow spa at the tops of columns are sometimes found to be due to this cause. As th are not always observable from the outside after the forms are removed, gr care should be exercised to guard against them. In pouring, therefore, t molds should be filled to overflowing to the top of deep molds.

(5) The exact position of the reinforcing-steel in the concrete is of such vi importance that particular mention is again made of it here. In loose-bar co struction the greatest care must be exercised, in the first place, to have the re forcement carefully placed, and then to avoid its being shifted out of positi by the pouring and the ramming of the concrete.

(6) The REINFORCING-STEEL of those systems in which the advantage of tached stirrups is claimed, is often, for convenience in shipping, sent with stirrups laid flat or close to the main bar. It is intended that in plac them on the job the stirrups shall be turned up to their proper positions. Unl carefully inspected, this is liable to be neglected.

(7) The use of a UNIT TYPE of construction (see page 922) practically obvia these two last-mentioned dangers, as the entire reinforcement comes framed gether, so that the relative positions of reinforcing-rods or bars cannot be chang and a glance will show whether the FRAME is complete or has been damaged, a when placed in the molds, whether it fits or not. In this type of construct the parts are all assembled in the shop from details carefully drawn and check in much the same way that steel beams, girders, columns, etc., are fabricated fr

p drawings. The work of the inspector or superintendent on the job
ı simplified, and hence the liability of error reduced to a minimum.

sts on Reinforced-Concrete Construction. Load tests on the
ıcture should only be resorted to when, all reasonable care having
ıd to obtain good results, some doubt still exists as to the results.
ıowever, should not be accepted in place of a strict compliance with
tions. The architect should know beforehand that his building is
igned and safe, and should employ, if necessary, an engineer. The
ıould understand at the outset that the structure has been designed
lefinite purposes and loads, and that the materials and details of
specified are not to be changed. If the contractor furnishes the
: sometimes does, a practice thoroughly condemned, the architect
ribe in his specifications that such design shall be checked and
an engineer appointed by him. A fair load to be applied in a test is
weight of the construction plus one-and-one-half times the working
he stresses in the construction are then equal to one-and-one-half
rking stresses assumed in designing. Under these conditions there
e any evidences of distress, and the deflections should not exceed
ı. The material used for the load test should be so selected and
when uniformly distributed, as required, it will not arch and assist
ive strength of the beam or floor. Pig iron is a very good material
ks are more generally available, but must often be piled very high
quired load, consuming much time and labor in making the test.
are used they should be set in vertical piles with spaces of 2 or 3 in
ı, thus avoiding all arching of the load.

CHAPTER XXV

REINFORCED-CONCRETE FACTORY AND MILL-CONSTRUCTION *

By

EMILE G. PERROT

MEMBER OF AMERICAN SOCIETY OF CIVIL ENGINEERS

General Principles. The problem involved in the proper design of a re forced-concrete factory or mill is a far more difficult one than might app from a superficial examination of the finished structure. This applies to bui ings constructed wholly or in part of reinforced concrete, and is due to the f that maximum economy and efficiency in production can only be obtai when the building is thoroughly adapted to a given occupancy and use. Laym and even some architects, look upon the factory as a mere workshop, consist of four walls with floors and roof. To them it seems an easy matter to loc the structure with reference to the lot or site and then supply it with stairwa elevators and kindred features. This, however, is not the case. Each indus uses processes peculiar to itself. The ease with which these processes can employed renders the profit-making more or less successful; hence it is nec sary to design the building to suit them. However, as the purpose here is explain what constitutes proper design, as applied to the reinforced-concr construction of a factory or mill-building, a typical case will serve to make cl the principles involved. This chapter, therefore, deals with such general ty as would seem to meet the needs of the greatest number of persons.

Walls, Floors and Roofs. Reinforced-concrete construction may be u for walls and floors, or for floors and roofs only, in the latter case substitut for reinforced-concrete walls some masonry construction such as brick or sto It is not always advisable to use reinforced concrete for walls. Circumstan very frequently arise in which it is more suitable and economical to use br walls or piers.

Types of Floor-Construction. The floor-construction may be divi into two general types, the BEAM-AND-SLAB type and the GIRDERLESS ty The beam-and-slab type may in turn be divided into varieties. For exampl may consist of beams supported by columns, with slabs spanning from beam beam. This arrangement corresponds to simple mill-construction in wood, wh the heavy timbers run across the building every 8 or 10 ft. The timbers r on the wall at one end and on a post at the other, with 3 or 4-in splined pla spanning from beam to beam. The earlier types of reinforced-concrete flo were patterned after this system. The next method was the introduction girders running from column to column, and the placing of the columns fart apart, say twice the distance common to the former system. The beams spaced as formerly. This may be called the BEAM-AND-GIRDER system. S another variation of the beam-and-slab type is the SQUARE-PANEL system,

* For Concrete in general and Mass-Concrete, see Chapter III, pages 240 to for Strength of Concrete without Reinforcement, Chapter V, pages 283 to 287; for Reinforced-Concrete Construction in General, see Chapter XXIV, the paragraph which, corresponding to the same details discussed here, should also be read. See, a Chapter XXIII, pages 817 and 844.

›eams are arranged along four sides of a square, a column being ıch of the four corners. The simplest type of reinforced-concrete for factories is some form of the beam-and-slab type with walls and forced concrete. The GIRDERLESS type consists of a heavy flat slab ı columns without the use of beams or girders. The column-head o form a large bearing-surface and the columns are spaced so as to bays as near as possible. A typical example is worked out at the hapter.

In general, as few columns as possible should be used to support ler that they may not interfere with the placing of machinery, and most economical use of the floor-space. From the standpoint of

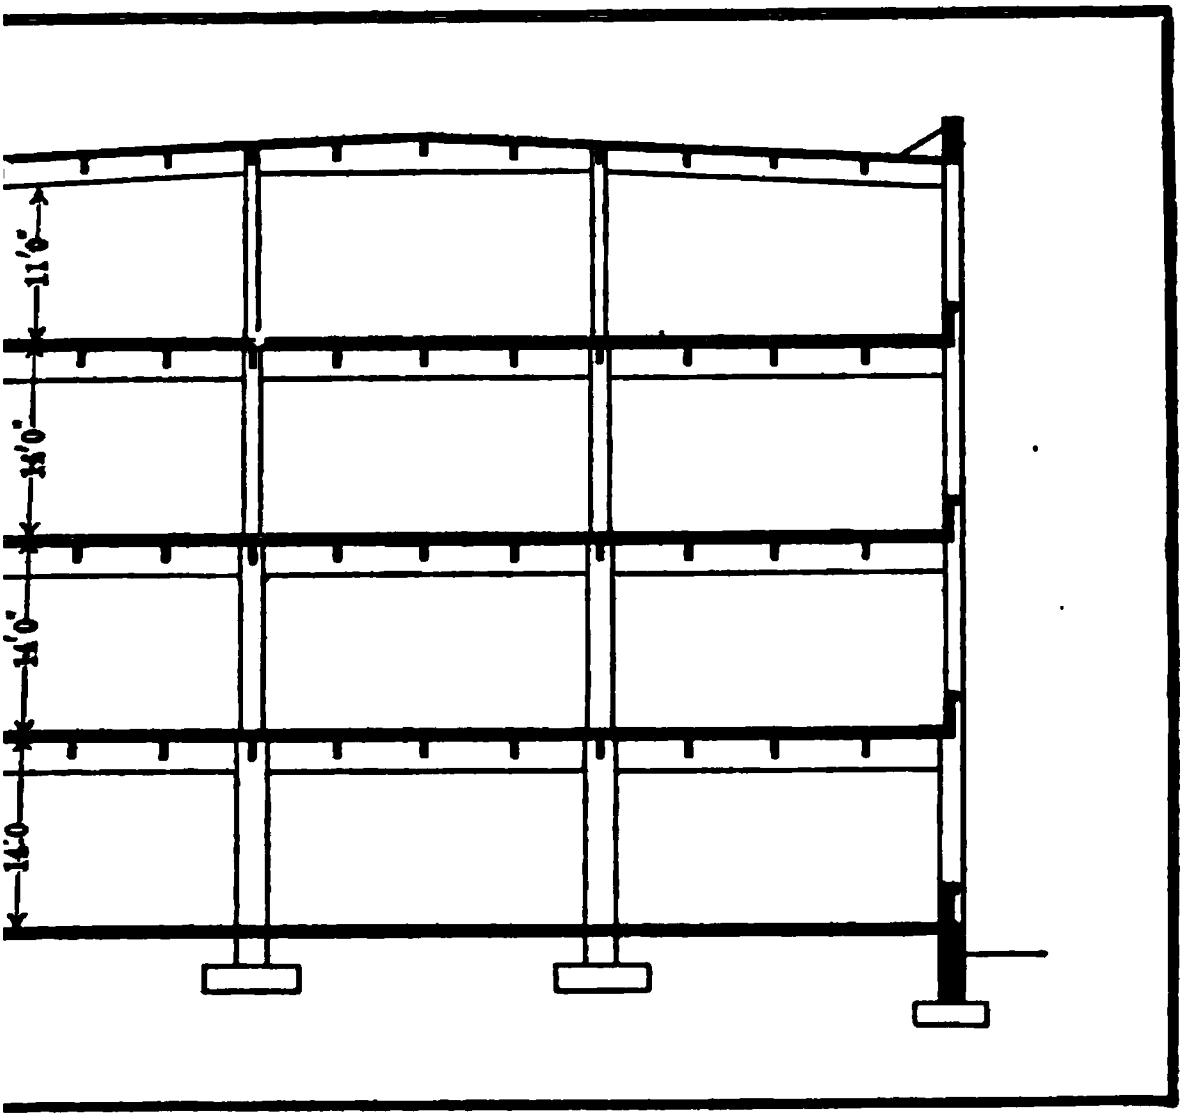

Fig. 1. Cross-section of Building

ıstruction, however, the use of one column to not more than or-space has been found to meet average requirements. This, ıot include construction of a special class. Adopting this, then, , and bearing in mind the fact that the nearer a building comes in plan the less is the total length of exterior wall required to area, it can be assumed that a four-story building 75 ft wide f columns, making three spans across the building, is a suitable ırposes. (See Fig. 1.)

g of a Building of this width, with story-heights of 14 ft, be ample for most purposes. There are always some parts of or which a strong light is not absolutely essential and which o aisles and to the storing of material in process of manufacture. : of the floor-space is generally used for this purpose, while the

machinery is placed nearer the windows where the light is best and where work is done. It is usually better, therefore, not to have a row of colu along the central axis of the building, unless it is definitely known that such arrangement will not interfere with the proper use of the floor-space. In building 75 ft wide, two rows of columns, with spans of 25 ft crosswise of structure, leave the central part of the floor-space free. Dividing 25 i 400 sq ft, the floor-space allowed for each column, gives 16 ft as the dista between columns, measuring lengthwise of the building

Bays. The reason in this instance for making the bays rectangular inst of square is that there would be another row of columns if a square bay w a maximum of 20 ft in either direction were assumed. This would be likely

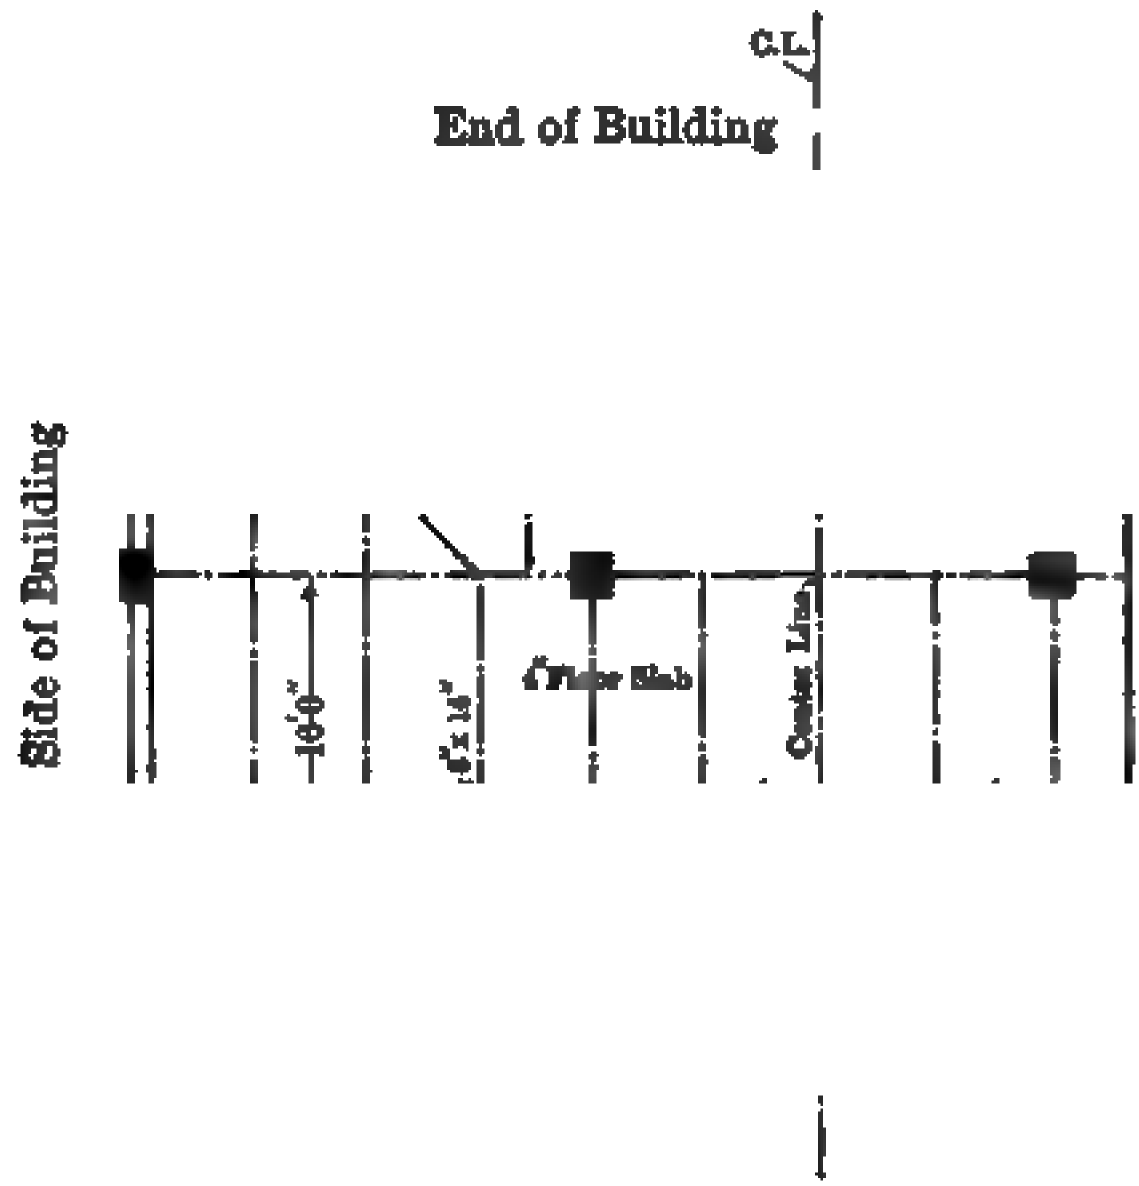

Fig. 2. Part Floor-plan of Building

interfere with the judicious placing of machinery and would result in a row columns along the central axis of the building. This is not considered g practice and should be avoided, except when there is to be only one row columns in the building.

Example of a Typical Bay The design of a typical bay of the size m tioned above, 25 by 16 ft, will now be considered. Referring to the illustrat (Figs. 1 and 2), it is seen that the windows occupy the major portion of the w area, the sill being set much lower than is usual in brick buildings. Th done to avoid the necessity of the construction of an extra-high spandrel be as the lintel over the windows below performs the double function of suppor the floor and forming a curtain wall. The head of the window is carried to the under side of the floor-slab to simplify the construction of the bot

and at the same time permit the window to extend to the ceiling, oducing the light at the highest possible point and allowing the rays r into the room. The first beam should be set as far back as possible side wall and windows, so that the angle of the direct rays of light early horizontal as practicable. It will be found best to have the run across the building, bearing on the walls and interior columns. s may be made as deep as economy of design suggests, as they run the light-rays and do not interfere with the lighting-scheme. Again, is relatively very economical. It also acts as a stiffener across the nension of the building, thus increasing the resistance to vibration oving machinery.

Floor-System. The various elements of the floor-system consist girders, beams and slabs. Each of these will be considered sepa- re load of 120 lb per sq ft is ample for light manufacturing purposes. oad prescribed by the Building Regulations of the City of Phila-

s. The spacing of the beams should be governed both by economy construction and the maximum distance a slab will span while load safely. It is impractical to make a slab less than 3 in thick. ght, with concrete weighing 150 lb per cu ft, is 37½ lb per sq ft. a 1-in cement finishing-coat, weighing 12½ lb per sq ft, to be laid te, the total live and dead load which the slab must carry, if it is 3 o lb + 50 lb = 170 lb per sq ft. Referring to the diagram of the einforced-concrete slabs (Fig. 18), calculated on a basis of the ent equaling $Wl/10$, no curve is found in the 3-in diagram for a o carry a load of 170 lb per sq ft. Some other slab must be used, arry the load.

Reinforcement. Referring to the diagram of the 4-in slab in llowing the 6-ft line until it intersects the horizontal line opposite q ft, it is found that a 4-in slab, reinforced with 0.195 sq in per lin n square bars per foot, will carry slightly more than is required for uestion. The total load, if the slab is 4 instead of 3 in thick, is q ft, and as the 187½-lb line is the nearest to this load, the 4-in d as above, is adopted. The reinforcing-rods are placed 1 in from the slab and are of sufficient length to extend over two spans and ch end; the joints are made over the beams and not in the space (Fig. 3).

s. The beams running from girder to girder are considered next span, center to center of girders, is 16 ft, and the distance apart ing an area of 100 sq ft carried by each beam. To the load per 182½ lb must be added the weight of the beam itself, which is 15 lb per sq ft of floor-area, making a total of 197½ lb per sq ft y the beam. This multiplied by the area, 100, equals 19 750 lb. oment caused by this load on the beam, based on the formula M = or partially restrained beams is the one generally used, is 379 200 b acts with the stem or beam to form a T beam and hence is as- e compression-flange of the girder; and as the slab is 4 in thick, the am and the amount of reinforcement can readily be found by refer- , which is the diagram of the strength of T beams having a 4-in m-depth in the diagram is the depth of the stem below the slab. n opposite the center of the space between 350 000 and 400 000 d side, the depth of beam that best suits the conditions can be t the bottom of the diagram is given the total area of steel to

be used in the reinforcing-rods. As the depth of a beam from the standpoin economical use of material should be about one-twelfth the span, a beam or 16 in deep is found to comply with this rule. Below the space where the l representing the 14-in depth of beam intersects the line representing the be ing moment, it is seen that the area of steel necessary is 1.8 sq in. Distribut

Fig. 8. Plan of One Bay, Showing Reinforcing

this over four bars, each bar should contain 0.45 sq in. The area of one 1⅛ square bar is 0.47 sq in, and hence a beam 14 in deep, reinforced with four 1⅛ square bars, is used. The width of the beam should be 6 in. A safe rule determine the width of the beam-stem is to allow 1½ in of concrete fireproo on the sides of the bars and arrange the bars in two rows, if the beams h three or more bars. The distance in a horizontal direction, center to cente bars, should be 2½ times the diameter, but in any case there should be a space between the bars horizontally, to permit the concrete to thoroughly in them.

Arrangement of the Bars. Assuming the bars to be twisted, the dista center to center, of the two bars is 1⅞ in. Adding to this the diameter of bars on their diagonal, which is about 1⅛ in, and 3 in for the fireproofing, sum is 6 in as the width of the beam required in this case (Fig. 6). It would perfectly practicable to arrange the four bars in one row across the bottom the beam; but the width would have to be 9⅝ in, which is wider than su requires. An additional objection to the latter arrangement is that it requ more concrete, thus adding to the dead weight of the construction. Th should be 2 in of concrete under the bottom of the rods for fireproofing.

Width of Beam. Of course, the width of the beam must be sufficient permit easy pouring of the concrete. Where wooden-box forms are used, i not good practice to make beams narrower than 6 in. If the beam is very d say 36 in, 6 in would be too narrow a width in which to place the steel a clean out the beam-forms. Practical considerations very frequently go the width of beams.

There should be in each beam and girder a sufficient number of le of at least 5/16-in round bars, bent U-shaped, run under the and extended up into the slab with an angle-bend 6 in long. If girder is short and excessively deep, 3/8-in round or heavier stirrups ed. The function of stirrups is to unite mechanically the slab to that perfect T-beam action will result, and also to assist in the DIAGONAL TENSION or SHEAR as it is commonly called. The num- s in a beam should be approximately one for each foot of the span, ter, but the spacing should be as stated below. Thus, a 16-ft have not less than sixteen stirrups, that is, eight on each side of e.

pacing for Distributed Loads. For beams with distributed rups are to be spaced so that the minimum distance between them in ordinary ne maximum nore than 36 iddle of the half of the be divided parts. The est the sup- contain ap- one-half the rups allotted he beam, or e total num- ddle division in one-sixth ber, and the to the cen- twelfth the as shown in distribution out evenly which comes this should

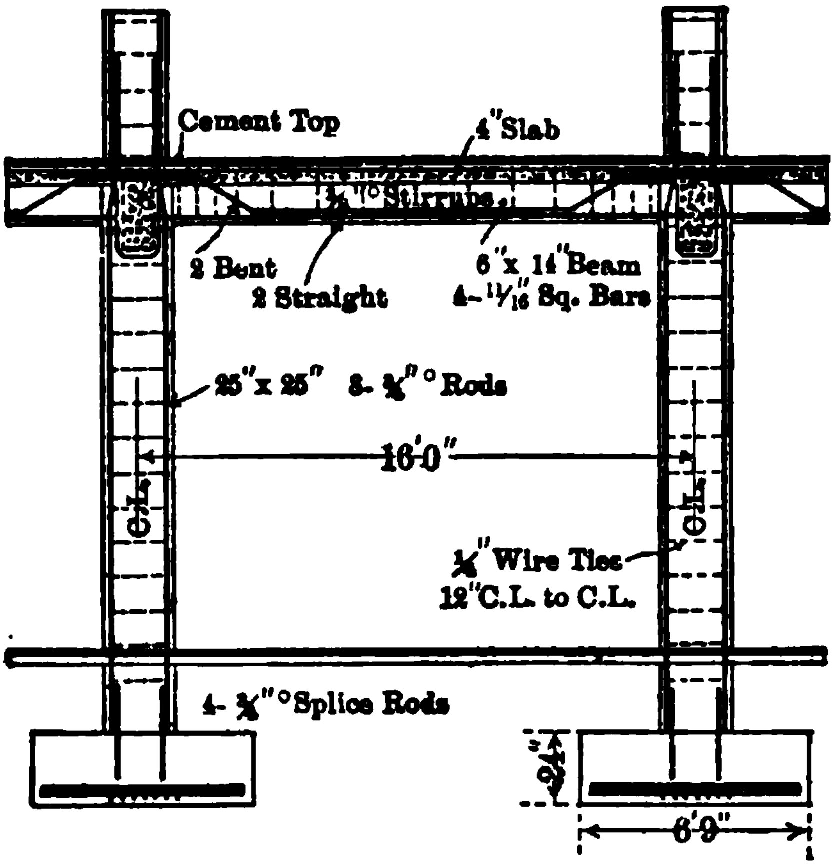

Fig. 4. Section Showing Elevation of Beam

acing for Concentrated Loads. When there are concentrated rups should be designed to suit the loading, but in any case, equal to about one-fifth the span from each end, the stirrups ced at least from 4 to 6 in on centers. A good rule to follow is ide of safety and to put in plenty of stirrups, if the determination umber is in doubt, as there should be a sufficient number of them part of the diagonal tension not safely resisted by the concrete.

gement of the Bars in the Beam is shown in Fig. 4. The are bent upwards near the supports to resist the negative bending a causes tension at the top of the beam near the supports. These tend into the next span at least 30 in to form a tie. As rein- e is of a monolithic character, it is necessary to introduce metal the concrete is subjected to tensile stresses. While it is not rovide as much steel at the top of the beam over the supports as restrained beams gives, if 50% of the area in the beam is carried

to the top and over the supports, as shown in the illustration, the beam will perfectly safe when calculated on a basis of M equaling $Wl/10$. In some citi beams must be calculated on the basis of $M = Wl/8$. Then it is only nec sary to have about one-fourth the number of the bars bent up near the support These bars, however, should extend at least 30 in beyond the center of t girder or column to tie the building together.

For Simple Beams with Uniformly Distributed Loads, all rods f 60% of the span should be straight and the truss-rods should bend up from t points so determined.

For Beams or Girders with Concentrated Loads, all bars are run straig as far as the concentrated loads extend. Beyond these loads, towards the su ports, one-half the number of bars may be bent up as above.

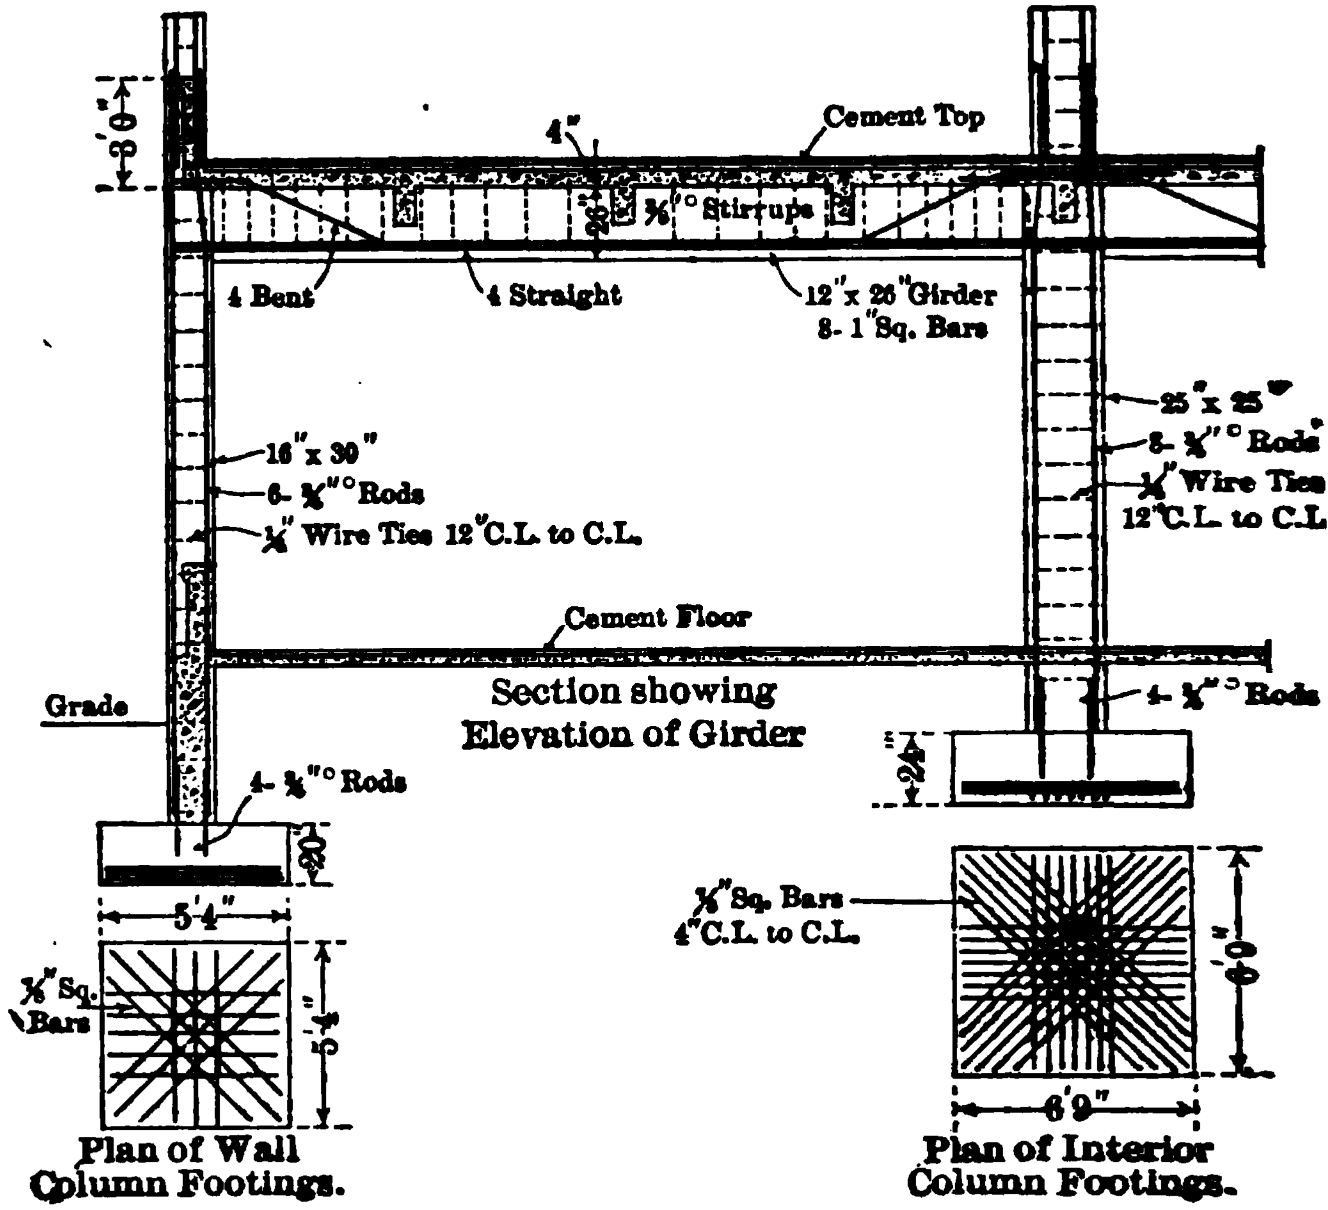

Fig. 5. Elevation of Girder and Plans of Column-Footings

The Girders. The girders running across the building are calculated on t basis of carrying their own weight as a uniformly distributed load and co centrated loads at the points where the beams frame into them. Referring the illustrations, Figs. 2 and 5, it will be noticed that there are three beams each side supported by the girder, the fourth beam being carried by the colum Each concentrated load equals the total load on the beams, or 19 750 lb. T weight of the girder can be assumed as 20 lb per sq ft of area carried, 20 × 4 = 8 000 lb. This acts as a distributed load. One-half the span of 25 ft, or 12

e bending moment at the middle of the girder from the con-
ibuted loads is

$$\times 150) - (19\,750 \times 75) + \frac{8\,000 \times 300}{8} = 3\,262\,500 \text{ in-lb}$$

s and Width of Girder. Referring again to Fig. 21, in ace opposite 3 300 000 and 3 250 000, the line of a 26-in deep tersect the vertical line representing 8 sq in of steel. Hence ars arranged in two horizontal rows are used. The width of n in order to have the proper distance between the bars and ive 1½ in of concrete fireproofing on the sides (Fig. 7).

section of Beam

Fig. 7. Cross-section of Girder

the Concrete Slab over the Girder is found by multiplying eel by the number on the line of the 26-in beam, which is t is used for any area of steel when the beam is 26 in deep, the ther beams are to be likewise used for their respective beams. girder, the width of the ⊤ beam is 8.7 × 8 = 69.6 in, or 34.8 the middle of the girder. The portion of the slab used at e girder or beam should not exceed on each side of the beam -thickness, nor one-third the span. In the case now being it is not exceeded. Similarly the width of the slab acting as ange of the 14-in beam is 1.8 × 12 = 21.6 in, twelve being the beams.

The next member to design is the lintel, or spandrel beam over 2, 5, and 8). This should be, for practical considerations, 6 in ttom of the lintel is flush with the bottom of the slab, the slab- o the lintel over the top of the lintel-rods. In addition to the tel there should be bars of the same size as the stirrup-bars, n apart and bent at right-angles, one leg extending up 12 in l the other 18 in out into the slab; or else the slab-bars should ding into the lintel 12 in. These make a perfect tie between l. The bottom of the lintel should be made with a rebate to of the window-frame. The load carried by the lintel is the b, the weight of the window and the dead weight of the lintel. floor-slab is 13½ ft (the clear span of the lintel) × 3 ft = 40½ the load per square foot on the floor-slab, or a total load from 371 lb. The total height of the lintel to the top of sill is 3 ft. k this makes the weight per lin ft 75 × 3 = 225 lb, the total el being 225 × 13½ = 3 038 lb. For the window 10 lb per sq ft area being 13½ × 11 ft, the height of the window, or in even

figures 149 sq ft, the weight is 149×10 lb = 1 490 lb. The total load on lintel, then, is 7 371 + 3 038 + 1 490 = 11 899 lb.

The Lintels Figured as Rectangular Beams. By referring to the paragr Explanation of Diagrams and Formulas, page 992, for the strength of rectang beams, it is seen that when reinforced with 0.5% of steel the safe load carried the beam is $W = wl = 48\frac{bd^2}{l}$. Hence, a 6 by (36 − 6)-in beam will carry $48\frac{6 \times}{13}$ = 15 552 lb. The depth 27 is used, as it is taken to the center of action the steel. This is more than the load upon the lintel and hence the linte safe. A reinforcement of 0.5% equals 0.005 of 162 sq in, the area of the concr or 0.81 sq in; and if two bars are u each must be of 0.4-sq-in sectional a Two ⅝-in square bars, each having area of 0.39 sq in, will be used. Th should be located 2 in from the botto and run straight. There should be t ⅝-in square bars near the top of lintel, running the full length, and fourt $^5/_{16}$-in stirrups, as shown in the illust tion (Fig. 8). The top bars take place of bent bars and also prev are vertical cracks which are liable to oc from shrinkage near the middle of lintel.

Fig. 8. Vertical Section, Showing Lintel

The Columns. Having establis the design of the floor-system, the dim sions of the wall piers, interior colum and footings are next determined. schedule of the loads on the inte columns will now be made.

The Load from the Roof. Assuming a live roof load of 30 lb per sq and 10 lb additional for accidental load from overhead shafting, the total l load is 40 lb per sq ft. The weight of the slab, if 3 in thick, which is as th as is usually required, is 37½ lb per sq ft. The beams and girders weigh anot 30 lb per sq ft (12 plus 18), making a total dead load of 70 lb, including t covering. Adding the live load of 40 lb to this gives 110 lb per sq ft as the to dead and live load.

The Load on the Fourth-Story Column, then, is 400 times 110 lb 44 000 lb, not counting the weight of the column itself. For practical reas no column should be made less than 10 by 10 in in cross-section. Allowi therefore, 500 lb per sq in unit stress on the concrete for columns, which is t unit stress allowed by the Philadelphia Building Bureau in reinforced-concr columns with vertical reinforcement, the carrying capacity of a 10 by 10 column is 100 times 500, or 50 000 lb, which is in excess of the load to be carri (See Table I.)

The Load on the Third-Story Column is the load from the one abo of 44 000 lb plus the load of one bay of the fourth floor, which is 217 lb × 4 = 86 800 lb, being the total dead and live load; or 86 800 + 44 000 = 130 800 lb, which must be added the weight of the column, which is assumed to be 300 lb lin ft. As it is about 11 ft long in the clear, the weight of the column is 3 300 which, added to 130 800 lb, equals 134 100 lb. The area of the cross-section a 16 by 16-in column is 256 sq in, which, at 500 lb per sq in, gives 128 000 lb

capacity. While this is 6 100 lb less than the load to be carried, of the required strength. It is customary to make a reducto be canied on the columns in proportion to the amount of the reduction being greater as the floor-area increases. Usuon of the LIVE LOAD per floor, with a maximum not exceeding m columns for high buildings, is considered good practice.

of Reinforced-Concrete Columns. Length, Fifteen Diameters

rtical bars. Safe working stress on concrete 500 lb per sq in, the being neglected in figuring the columns

Area	Total safe loads in lb	Size	Area	Total safe loads in lb
64	32 000	18×18	324	162 000
81	40 500	19×19	361	180 500
100	50 000	20×20	400	200 000
121	60 500	21×21	441	220 500
144	72 000	22×22	484	242 000
169	84 500	23×23	529	264 500
196	98 000	24×24	576	288 000
225	112 500	25×25	625	312 500
256	128 000	26×26	676	338 000
289	144 500	27×27	729	364 500

he Second-Story Column is 134 100 lb plus the load from the weight of the columns, all of which is assumed as being h-floor load and weight of column, or 90 100 lb, making the A 21 by 21-in column will carry 441 times 500 lb per sq in,

he First-Story Column is 224 200 lb plus the second-floor and the weight of the column, which, at 600 lb per lin ft, is of 317 600 lb. A 25 by 25-in column will carry 625 times or 312 500 lb, which is almost the required strength. The hen becomes

For the first story 25 × 25 in in cross-section.
For the second story 21 × 21 in in cross-section.
For the third story 16 × 16 in in cross-section.
For the fourth story 10 × 10 in in cross-section.

nent in the Columns should consist of eight ¾-in round er and four in the two upper stories, with ties of ¼-in round s shown in Fig. 9. It is the custom to use the same unit concrete columns up to 15 diameters, and not to use columns ls 15 diameters.

s. The schedule of all the wall piers is made by the e interior columns. The details of the calculations are not ults only being given. The size of the wall piers is deterhitectural effect desired and by practical considerations. the smallest face-dimension of the piers, this size should ll height of the building (Fig. 10). The reveal of the piers 5 in, and the spandrels should line up flush with the inside o doing they are not made extremely thick. Reinforced-

concrete spandrels may be 6 in thick and give good results. It is not wis make them thinner than this, on account of the difficulty of constructing th It is to be noticed, also, that the lintels or spandrel beams act as ties from wall pier to another. They should be of sufficient strength not only to carry vertical loads coming upon them, but also to act as braces to take up any vi

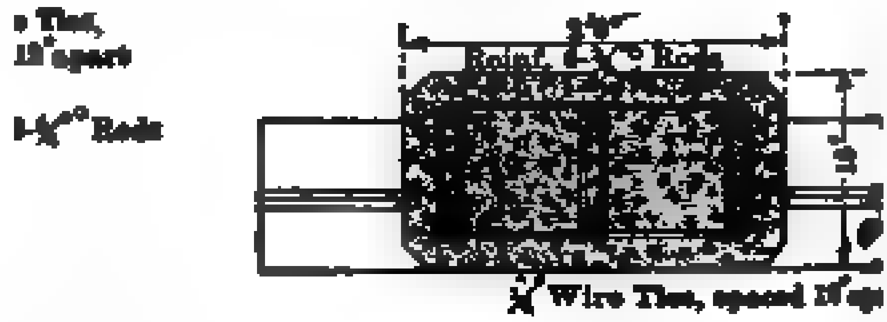

Fig. 9. Interior Column Fig. 10. First-story Wall Pier

tion in the direction of the length of the building; just as the deep cross-girde resist the vibration in the direction of the width of the building. Very fr quently the main girders are run lengthwise of the building, that is, spann the shortest distance, while the beams run across the building. Sometim this will make the construction more economical; but the reduced height the windows in the side walls due to the necessity of lowering the window-hea to permit the beams to be carried by a lintel running over them, is objectionabl as the light from the windows in this position is not as effective as when th are run up to the under side of the floor-slab or ceiling.

The wall-pier schedule, figured on the assumption above, becomes

For the first story 30 × 16 in in cross-section.
For the second story 30 × 12 in in cross-section.
For the third story 30 × 12 in in cross-section.
For the fourth story 30 × 12 in in cross-section.

It will be noticed that the piers in the three upper stories are of the sa dimensions. This is due to practical requirements, the reveal of the pier the spandrel being 6 in and the minimum spandrel-thickness 6 in. The p must be 12 in in order to be flush on the inside of the building.

Spread Foundations. The use of reinforced concrete for the footings a building results in economical construction when it is necessary to project t base or footing more than is customary or permissible without reinforcement some kind. In order to give sufficient information for the design of the found tions for the building under discussion in this chapter, as well as for other typ of construction met with in practice, several examples are worked out in t following pages. The simplest form of reinforced concrete SPREAD FOOTING shown in Fig. 5 and consists in considering the overhanging portions of t footings as CANTILEVER BEAMS. The footings of the interior columns are d signed as explained in the following paragraphs.

The Load on the Footing. The load on the footing is assumed to 317 000 lb and the safe bearing value of the soil 7 000 lb per sq ft. This requi a spread footing of 317 000 lb divided by 7 000, or 45 sq ft. The side of t square which comes the nearest to this area is 6 ft 9 in and its area is 45.5 sq f

The Design of the Footing. The footing is designed as follows: As ea square foot of footing sustains an upward pressure of 7 000 lb, the overhangi portion is treated as a CANTILEVER BEAM UNIFORMLY LOADED. The load directl

umn proper causes no bending, and this load is neglected in finding moment. The rods should be run as shown in Fig. 5, some diagone at right-angles to the sides, the first layer located 3 in from the footing. The size of the rods on the diagonal is now to be de- the others are to be made the same size. The longest length of diagonal cantilever is 4 ft, measured from the center of the column tion of the 1-ft-wide strip with the side of the square. The bend- n this strip is equal to the load on an area, outside of the column, 1 ft wide, or (3 × 7 000 = 21 000 lb) × 30 in = 630 000 in-lb, 30 in nce from axis of the column to center of gravity of the area.

e footing to be 24 in thick over-all, the CENTER OF ACTION of the out 5 in up from the bottom, making an EFFECTIVE DEPTH of 19 in. m for the steel is nine-tenths * of the depth when the stress in the lb per square inch, the resulting stress per square inch in the steel ess 16 000), is 16 000 × 0.9 = 14 400. As the bending moment lb, the number of square inches of steel necessary per foot

$$\frac{630\,000}{400 \times 19} = 2.34 \text{ sq in.}$$

This formula is for rectangular beams ng moment is given. (See Formula (1), page 992.) Spacing the nters requires three rods per foot, each requiring a cross-section in. As a 7/8-in square bar has a section-area of 0.76 sq in, this l. The bars in the layers at right-angles to the side are made the paced as above, so as to avoid complications in the construction It would be possible to space these farther apart, but this re- ecessary. (See Fig. 5.)

d on a column is such as to require a footing more than 2 ft thick, to slope the top of the footing, thus saving in the quantity of to provide a concrete PLINTH or BLOCK at the bottom of the of the footing so as to reduce the projection of the footing and a more economical design. If steel column-cores or hooped ertical reinforcements are used, a metal base-plate is necessary oting of sufficient size to limit the direct stress on the footing to

tions for the Outside Walls may be designed in either of as CONTINUOUS FOOTINGS such as are usual in ordinary construc- ly, as ISOLATED PIERS under the wall columns. In the first case o reinforce the footings and foundation-walls, as these act as ms loaded at each column, and must be made strong enough to ads from the columns uniformly over the entire length of the oundation-walls and footings can be treated as INVERTED CON- (Fig. 11), the upward reaction of the earth being considered a uted load on the beams, and the wall piers being considered as ng the beams, with the load on each pier as equal to the load on Fig. 12 shows the arrangement of the reinforcing-rods. Their d as explained in the following paragraph.

per running foot of the foundation is equal to the load from a e distance apart of the piers, omitting the weight of the spandrel ory windows, this load per running foot = 191 140 lb, the load 6 ft = 11 946 lb. As great refinements in calculations are not g-work of this kind, because of the advisability of large factors part of the building and the small reduction in cost due to any he strength of this continuous beam is calculated by the formula

), page 683; (4), 926; (6), 932; (1), 992; and Fig. 5, page 974.

$M = Wl/8$, assuming l to be the clear distance between the piers, or, in this ca
13 ft 6 in (Fig. 12). Therefore, $W = 13\frac{1}{2} \times 11\,946 = 161\,271$ lb and the be
ing moment $M = (161\,271 \times 162)/8 = 3\,265\,737$ in lb. As the size of the be
is determined by the thickness of the wall and its depth, all that is necessary is

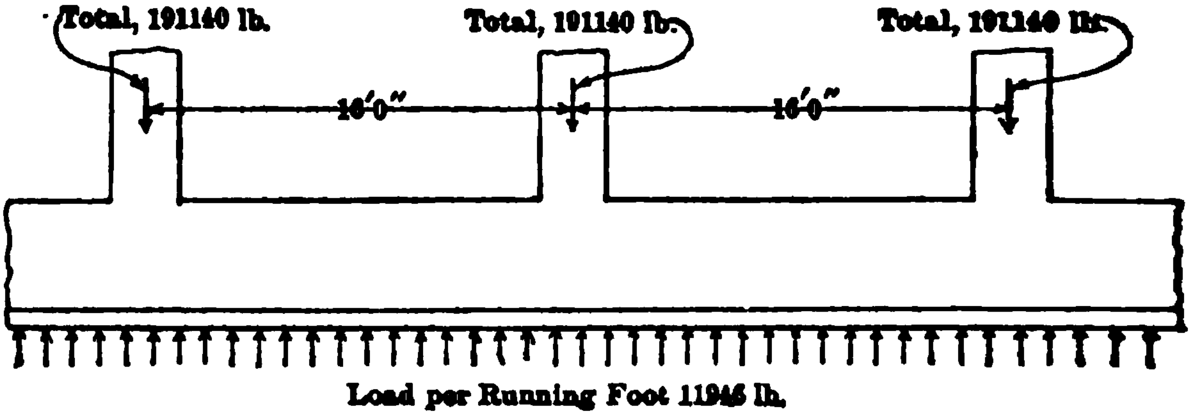

Fig. 11. Foundation-wall an Inverted Continuous Beam

find the AREA OF THE STEEL by referring to Formula (1), page 992, which gi
$A = \dfrac{M}{14\,400\,d}$, or $A = \dfrac{3\,265\,737}{14\,400 \times 52} = 4.3$ sq in, distributed in eight ¾-in squ
bars with a total area of cross-section of 4.48 in. These are in two layers, f
running straight and four bent as shown in Fig. 12. The top layer is placed 1

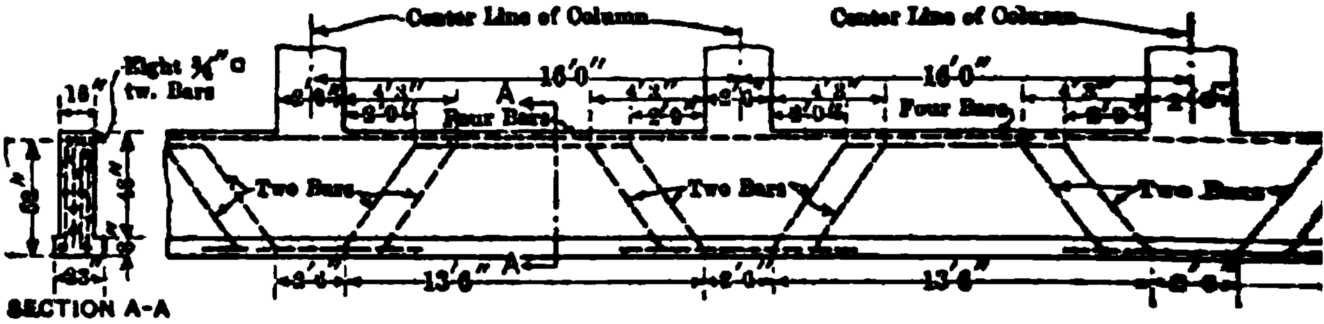

Fig. 12. Arrangement of Rods in Foundation-wall

from the top of the concrete. The footing is made wider than the wall to k
the load on the soil within the safe limit of 7 000 lb per sq ft. The width
determined as follows. As the column-spacing is 16 ft, center to center, 7 000 ×
= 112 000 lb, the load the foundation 1 ft wide and 16 ft long will carry; ha
to carry 212 120 lb (the load from the pier, plus 20 980 lb, the weight of
spandrel and footing), 212 120 is divided by 112 000, giving 1.9 ft for the wi
of the footing, or 1 ft 11 in, nearly.

Isolated Piers. In the second case, a SPREAD FOOTING is provided un
each wall column in the same manner as under the interior columns, but desig
for the lighter load. The foundation or spandrel wall is not made as heavy
in the first case, as it carries no load except its own weight and the wall or wind
above it. (See Fig. 5.) WHERE THE SOIL IS BAD and of low carrying capac
the PIER-METHOD is found to make an economical foundation, especially whe
is necessary to use piling under the building, as the piles can be grouped un
the piers and columns, and capped with reinforced concrete. The foundatio
spandrel walls, properly reinforced, can be carried from pile-cap to pile-cap
they do not depend on the soil directly under them to sustain the load.

Combined Column-Footings. It very frequently happens that a bui
ing is to be built adjacent to and abutting on a property-line, and as
foundations must not encroach upon the adjacent property the columns mus

the footings. In order to secure uniform soil-pressure it is
ombine an interior with an exterior column-footing so as to
uniformly from the two columns to the soil below. Some-
to combine the footings of more than two columns. Fig. 13

he BENDING MOMENT in the footing. We assume an area
, giving a soil-pressure of 1 490 000 lb ÷ 224 sq ft = 6 650
7 = 46 550 lb per running foot. The point of maximum
ere the vertical shear is zero and is determined by the
o = 15 ft. Also, 15 ft − 1.05 ft = 13.95 ft. Hence

o × 13.95) = 9 765 000 ft lb] − [(46 550 × 15 × 7½)
5 ft lb] = (4 528 125 × 12) = 54 337 500 in lb

The 1.05 ft is one-half the column-width, 2 ft 1 in.

We may determine the DEPTH OF THE FOUNDATION by assuming a c sectional area of the reinforcing-steel and solving in Formula (1), page 99 the depth. For practical considerations square bars larger than 1¼ in sq should not be used; hence by trial we find that thirty 1¼-in square bars w section-area of 46.8 sq in, placed in two rows in the top part of the founda will space out just right for a width of beam of 64 in, which is 6 in wider the 58-in dimension of Column No. 1. The depth then by this formula i

$$d = \frac{M}{14\,400\,A}, \text{ or } d = \frac{54\,337\,500}{14\,400 \times 46.8} = 80 \text{ in},$$

the depth from the center of the steel to the bottom of the concrete. There 80 + 4 = 84 in, the total depth of the foundation.

The WIDTH OF THE FOOTING AT THE BASE must be increased to keep the

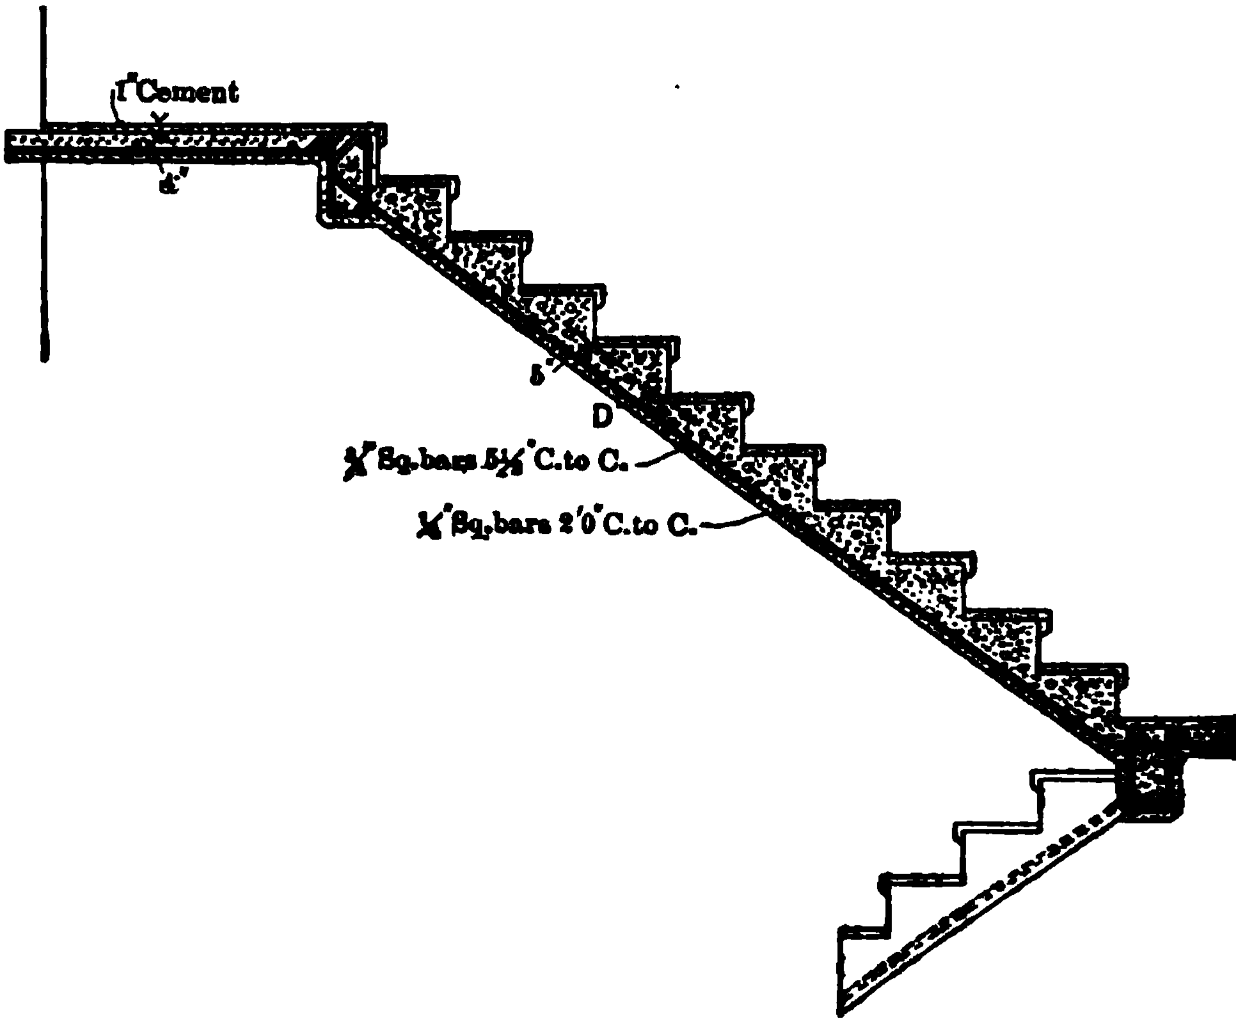

Fig. 14. Section through Flight of Reinforced-concrete Stairs

stress on the concrete in compression within the allowable stress, 600 lb per As the total horizontal compression in the beam must equal the total tens order to satisfy the requirements for equilibrium, we have total tension = lb per sq in × 46.8 sq in = 748 800 lb. From Table V, page 930, Chapter X the depth of the AREA OF THE CONCRETE IN COMPRESSION is equal to 0.3 = 24.8 in. The width is found by dividing 748 800 by (300 × 24.8 = the resistance of the concrete per inch in width of the beam, which gives 89 the width of the concrete at the bottom of the footing, 300 lb being the av unit stress on the area of the concrete in compression, since the stress act

600 lb on the outside upper surface of the concrete to zero at the

s. The ease with which stairs can be built of reinforced concrete has
eral adoption for this purpose in reinforced-concrete buildings. As
erally enclosed in stair-towers or shafts, their construction usually
n of the double run or half-pace type (Fig. 14). This reduces the
run so that the construction does not become too heavy. Each run
nsidered as an inclined beam and is so figured, being supported at
bottom on the stair-landing header-beam. The rods are placed
om of the slab and run continuously from top to bottom. The
beam is considered to be equal to the distance from the soffit of
he corner formed by the tread and rise, as shown by the letter D
he landings are figured the same as floor-slabs. Their supporting
culated to carry the load coming upon them from the landing and
r stair-run, which starts from the landing-beam. The lower stair-
p under the landing-beam, acts as an inclined strut and supports
beam. Hence the span of the landing-beam is equal to the distance
of the stair-tower or
side edge of the stair-
w, and is a little more

g. 23. Diagram for Strength of T Beams

The following formulas are for the strength of rectangular beams or slal based on various percentages of steel, the beams being considered to be as simp supported at the ends. They are calculated in accordance with the Philadelph requirements, and can be used in investigating the strength of rectangul beams and slabs without obtaining the bending moment. They are very co venient in checking up a design already made, or in establishing the area of t steel reinforcement when the size of the concrete beam or slab is fixed, as show by the example given.

w = load in pounds per running foot;
b = breadth of beam in inches;
d = depth to center of action of steel in inches;
l = span in feet;
p = percentage of steel to area of concrete above center of steel to top of bea

When $p = 0.5\%$ then $w = 48\dfrac{bd^2}{l^2}$

$$p = 0.6\% \qquad w = 56\frac{bd^2}{l^2}$$

$$p = 0.7\% \qquad w = 59\frac{bd^2}{l^2}$$

$$p = 0.8\% \qquad w = 62\frac{bd^2}{l^2}$$

$$p = 0.9\% \qquad w = 64.5\frac{bd^2}{l^2}$$

$$p = 1\% \qquad w = 67\frac{bd^2}{l^2}$$

Example. Find the total load per square foot that can be carried by a 4 slab, with a 5-ft clear span, reinforced with 0.8% of steel per running foot.

Solution.

$$w = 62 \times \frac{12 \times 3^2}{5^2} = 62 \times \frac{108}{25} = 266.6 \text{ lb}$$

From this must be deducted the weight of slab and floor-finish to obtain live load. If finished with 1-in cement top coat laid directly on the conc the total dead weight is 62½ lb, which, deducted from 266.6 lb, leaves 204.1

Note. If the total load carried by the beam is desired, use l instead o in the formula. These formulas are based upon the stress in the concrete exceeding 600 lb per sq in and a tension in the steel of 16 000 lb per sq in, a ratio of the moduli of elasticity of the concrete and steel equal to 12.

Formula for the Resisting Moment of Rectangular or T Beams. T is Formula (6), page 932, Chapter XXIV, only in a different form, and is to used when the percentage of steel is not greater than 0.58 of 1%.

M = the maximum bending moment in inch-pounds;
d = the depth from the top of the beam to the center of action of the stee inches;
A = the area of the sum of the cross-sections of the steel bars in square inc

$$M = A \times 16\,000 \times 0.9\,d \text{ or } A = \frac{M}{14\,400\,d}$$

or $$d = \frac{M}{14\,400\,A} \quad . \; . \; . \; . \; . \; . \; . \; . \; . \; . \; . \; .$$

Given a bending moment of 217 728 in-lb and a depth (over all) in, to find the sectional area of steel necessary to make the resisting l to the bending moment.

$$A = \frac{M}{14\,400\,d} \text{ or } A = \frac{217\,728}{14\,400 \times 13\frac{1}{2}} = 1.12 \text{ sq in.}$$

ound bars of ¾-in diameter we have 0.56 sq in × 2, or 1.12 sq in. for fireproofing and ½ in to the center of the bars, the effective eam is reduced to 13½ in. For the width of the beam we can use age 931, Chapter XXIV, substituting for K the value correspond-t stresses and the ratio of the moduli of elasticity for the con- we have been using, namely, 600 and 16 000 lb per sq in for the nd 12 for the ratio. This value of K, from Table V, page 926, ', is 83.4 and $M = 83.4\,bd^2$. Transposing, we have

$$\frac{M}{3.4\,d^2}, \text{ or } b = \frac{217\,728}{83.4 \times (13\frac{1}{2})^2} = \frac{217\,728}{83.4 \times 182.2} = 14.3 \text{ in}$$

erefore will be 14½ in × 16 in in cross-section, reinforced with two s placed so that there will be 2½ in from the bottom of the beam As the width of this beam is excessive for the number of rods nomical. It would be better to design the beam with a T section dth to 6 in for the stem and making the top flange 14½ in wide = 4.18 in thick. The ratio of the distance of the neutral surface f the beam to the effective depth of the beam, for the values we is 0.31 (see Table V, page 926, Chapter XXIV), and in order to concrete in compression at the top of the beam to balance the the steel, the head or flange of the T must extend from the top e neutral surface.

loors.* In order to familiarize the student with the design of RS, an example is worked out, in which the area of a panel or bay 400 sq ft, the same as that of a typical bay in the factory-build- idered in this chapter. The column-spacing is made the same s, so that the panels are square, with a length of side of 20 ft. ng the various methods of computing the strength of flat, re- plates, we will use one under consideration by the Bureau of ion of Philadelphia.† This is a conservative method. It has orked out in all its details and applications and gives results safety and economical design. The following paragraphs set n and equations of this method as published by the Philadelphia ls it the DROP-CONSTRUCTION.

n, center to center of columns, of the longest of straight bands es.

nce or width, edge to edge, between capital-heads in inches dead and live load per square foot.

ce from the center of action of the concrete in compression to ter of the steel at the drop in inches.

ce from the center of action of the concrete in compression to ter of the steel at the center of the slab in inches.

* pter XXIV, pages 949 to 951. Flat-Slab Construction.

† rk, Chief of the Bureau of Building Inspection, Philadelphia, Pa., is orking out and perfecting the practical applications of this method.

If the drop-construction is not used, $d = d_1$.

Sufficient depth of slab is to be provided for shearing-stresses as well as bending-stresses.

Width of capital-head = not less than 2/10 L.

Width of drop = 38/100 L.

Width of bands = 45/100 L.

x = the area of section of steel over the capital-head.

x_1 = the area of section of steel in center of bay.

$-M$ = the bending moment at the edge of the capital-head.

$+M$ = the bending moment at the center of the span.

$$\text{The load carried by the straight band} = \frac{\text{total bay} - \text{capital-head}}{2} \times w$$

$$-M = \frac{\text{total bay} - \text{capital-head}}{2} \times \frac{wL_1}{12}$$

$$+M = \frac{\text{total bay} - \text{capital-head}}{2} \times \frac{wL_1}{24}$$

Width of concrete to resist compression at edge of capital-head = width drop.

Width of concrete to resist compression when negative moment = $-$

= width of band.

Width of concrete to resist compression at middle of span = width of ba

$$x = -\frac{M}{d \times 16\,000}$$

Place 66% of x in straight bands } over capital-head.
Place 43% of x in diagonal bands }

$$x_1 = +\frac{M}{d_1 \times 16000}$$

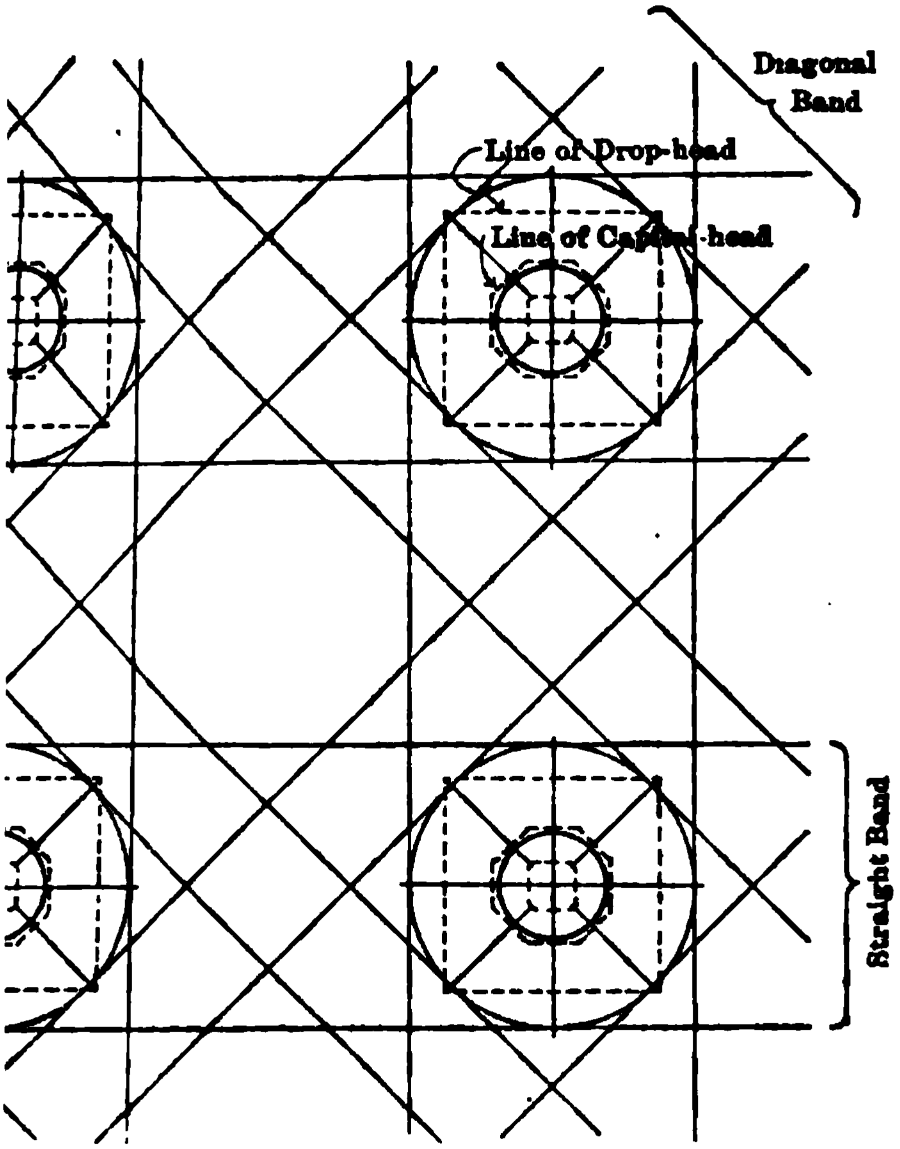
Place 66% of x_1 in straight bands } at middle of span.
Place 43% of x_1 in diagonal bands }

Add 20% of steel of $-M$ to provide for negative bending over straight ba

The drop equals the abacus outside of the capital-head, or the incre thickness of the concrete to obtain the necessary compression in the conc This is not generally necessary when the live load of the floor is light, say 1 per sq ft and the span is not excessive. To determine d and d_1 deduct from total thickness of the slab 1 in to the center of the steel when the rods are or less in diameter; if over ⅝ in deduct 1½ in; and multiply the result by The result will be the distance from the center of the steel to the center of a of the compressive stresses in the concrete.

The depth h is the distance from the top of the slab to the center of the and is used in finding the thickness of the slab. Applying the above form to the example considered, using a floor-load of 120 lb per sq ft as in the prev example, and assuming an average slab-thickness of 8 in with a 1-in top fi coat of cement, the dead load is 100 lb + 13 lb = 113 lb, which added to th load = 233 lb, total.

The arrangement of the bands is shown in plan, Fig. 24, the width being 4 or 45/100 the span of 20 ft, which is 9 ft. The diameter of the column-head is or 4 ft. The width of the drop is 38/100 L, or 7 ft 7 in.



4. Arrangement of Bands in Girderless Floor

e bay $= 20^2 = 400$ sq ft.
ital-head $= 4^2 = 16$ sq ft. Then, by the formula, the load
t bands $= \dfrac{400-16}{2} \times 233 = 44\,736$ lb

$$\frac{\ 736 \times L_1}{12} = \frac{44\,736 \times 16 \times 12}{12} = 715\,776 \text{ in-lb}$$

$$\frac{\ 736 \times L_1}{24} = \frac{44\,736 \times 16 \times 12}{24} = 357\,888 \text{ in-lb}$$

t diagram is shown in Fig. 25.
to find the thickness of the concrete at the drop. The
e depth of a beam when the bending moment, the width
owable stresses are given, is as follows, in which h equals
ab from the center of the steel to the top of the concrete:

$$\sqrt{\frac{M}{\ bS_c}} = \sqrt{\frac{2 \times 715\,776}{0.27 \times 91 \times 600}} = \sqrt{100} = 10 \text{ in}$$

the width of the drop and $S_c = 600$ lb per sq in. The
all, therefore, is $10 + 1 = 11$ in (Fig. 26).

lumn at the drop $= x = -\dfrac{M}{d \times 16\,000}$ in which $d = 0.9\,h$

$$\frac{715\,776}{9 \times 16\,000} = 4.9 \text{ in, or about } 5 \text{ in}$$

The straight band will have 66% of 5 or 3.3 sq in of steel. A 3/8 round rod h a cross-sectional area of 0.11 sq in. Therefore, there will be $\frac{3.3}{0.11} = 30$ bars ov the capital-head in the straight band. As the bars from the adjoining span ov lap the column-head, extending into the next span as far as the edge of the dr each straight band over the column will have 30/2 or fifteen bars. The diago

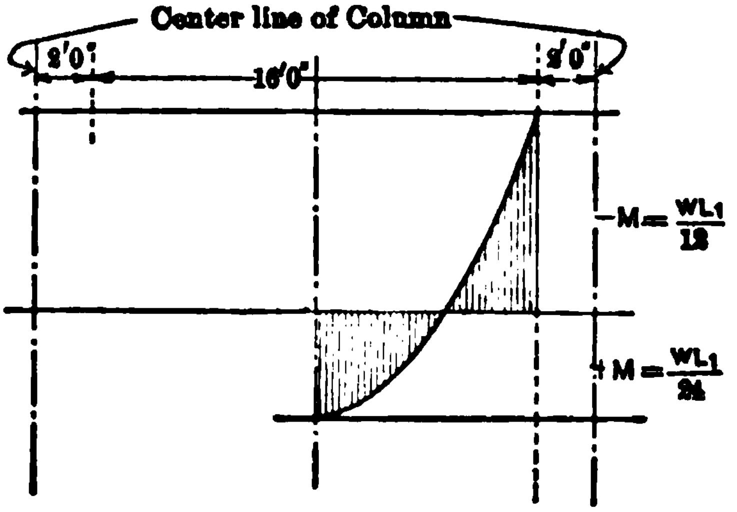


Fig. 25. Bending-moment Diagram for Girderless Floor

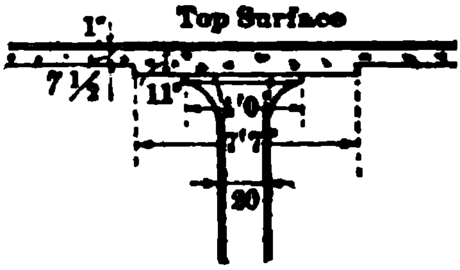

Fig. 26. Capital-head and S in Girderless Floor

bands will have 43% of 5 or 2.15 sq in, which will require twenty 3/8-in ro rods over the column, or ten on each side, lapped as above. The thicknes the slab at the middle of the span is found by the formula given above, sub tuting the proper values for the letters. The formula becomes

$$h = \sqrt{\frac{2 \times 357\,888}{0.27 \times 108 \times 600}} = \sqrt{\frac{715\,776}{17\,496}} = \sqrt{41} = 6.4 \text{ in}$$

The total depth is 6.4 + 1 in = 7.4 in, or about 7.5 in.
The width of the band = 9 ft = 108 in.
For the steel at the center of the span

$$x_1 = + \frac{M}{d_1 \times 16\,000} \text{ in which } d_1 = 0.9 h \text{ or } 0.9 \times 6.4 = 5.76 \text{ i}$$

$$x_1 = \frac{357\,888}{5.76 \times 16\,000} = 3.9 \text{ sq in}$$

The straight bands will have 66% of 3.9 or 2.57 sq in of steel which wi quire $\frac{2.57}{0.11}$ = twenty-three 3/8-in round bars or eight bars more for the m of the span than for the band set over the column.

In practice the rods are made the full length of the span, from colum column, plus the width of the drop, or in this example 20 ft + 7 ft 7 in = 27 f for the fifteen rods. Eight additional rods, 13 ft long or about the distance the edge of one drop to the edge of the next one, must be used with the fifte make the twenty-three required for the middle of the span. The diagonal b will have in the center 43% of 3.9 sq in = 1.68 sq in which require fifteen round rods or five more than one set of rods over the column. These five, ever, are to be added at the middle of the span between the drops. The are bent up over the column-head so as to be near the top of the slab to tak of the negative bending moment, the bars extending horizontally near th of the slab the full width of the drop. It is necessary to provide bent radia extending down into the column and outwards as far as the outer ring wit

as reinforcements of the column-head. The size and number of
rith the span and load; but for the floor under consideration there
ht 1-in radial rods as near the top of the slab as practicable, the
ne outer one being equal to the width of the band and that of the
g equal to the capital-head. It will be noticed in the above analysis
ıy calculations could be made certain assumptions were necessary,
ickness of the slab, which was assumed as 8 in, in order to obtain
whereas in the finished design the thickness of the slab is 7.5 in and
, which, however, does not affect the practical results materially.
ason that the design of flat slabs should be intrusted only to those
experience in the design of reinforced concrete, as good judgment
making up of a successful design; and one who is inexperienced
a specialist in this particular system of construction, if a design
to execution.

CHAPTER XXVI

TYPES OF ROOF-TRUSSES

By

MALVERD A. HOWE

PROFESSOR EMERITUS OF CIVIL ENGINEERING, ROSE POLYTECHNIC INSTITUTE

1. Definitions

Use of Trusses. Whenever the distance between the side walls of a buil ing exceeds about thirty feet, and there are no intermediate walls or columns, is usually necessary to support the roof on trusses. The ceilings of large room assembly-halls, etc., also, require trusses for their support. In many cases t roof and a ceiling are carried by the same trusses.

A Truss is a framework, composed of straight, or sometimes curved, me bers or pieces so arranged that the structure as a whole acts as a beam. Sin a triangle is the only figure which cannot be changed in shape without changi the length of one or more of its sides, it follows that the pieces forming a tr must be arranged so as to form triangles. The members of a truss are usua subjected to longitudinal stresses only, either compressive or tensile. Curv members and members which act as beams supporting loads are subjected additional bending stresses. Each member of a truss is either a TIE or a STRU

A Tie is a member which has developed in it a longitudinal tensile stress.

A Strut is a member which has developed in it a longitudinal compressi stress. When vertical, struts are sometimes called POSTS or COLUMNS.

The Top Chord of a truss is composed of the upper outside members. some forms of roof-trusses top chords are called RAFTERS (Fig. 2).

The Bottom Chord of a truss is composed of the lower outside memb (Fig. 2). In roof-trusses the bottom chord is commonly called the TIE-BEA

The Web-Members are those connecting the CHORDS (Fig. 2).

A Joint is the point of intersection of two or more members of a truss (Fig.

A Panel is the distance between two adjacent JOINTS in either the upper lower chords (Fig. 2).

Purlins. Whenever possible all roof-loads and ceiling-loads should be tra ferred to trusses at the joints. This usually requires beams spanning the sp between trusses at corresponding joints. These beams, when supporting roof, are called PURLINS (Fig. 2).

2. Types of Wooden Trusses

The Simplest Truss that can be built is that shown in Fig. 1. It consi of three members forming a triangle. As the unsupported length of a st for economical reasons, should not exceed 12 feet, such a truss is not suita for spans exceeding from 20 to 24 ft; and even for a span of 20 ft there sho be a center rod, as shown by the dotted line *R*, to support the tie-beam. utilize this truss for spans greater than 24 ft, it is necessary to brace the raft from the foot of the center rod, as shown in Fig. 2. This gives us the KING-R TRUSS, the modern type of the old-fashioned KING-POST TRUSS which is sho

which was built wholly of wood except for the iron straps at *S*

Braces. When the tie-beam supports a ceiling or attic-floor, rods
ıerted at *RR*, Figs. 2 and 4, to support the load on the tie-beam.

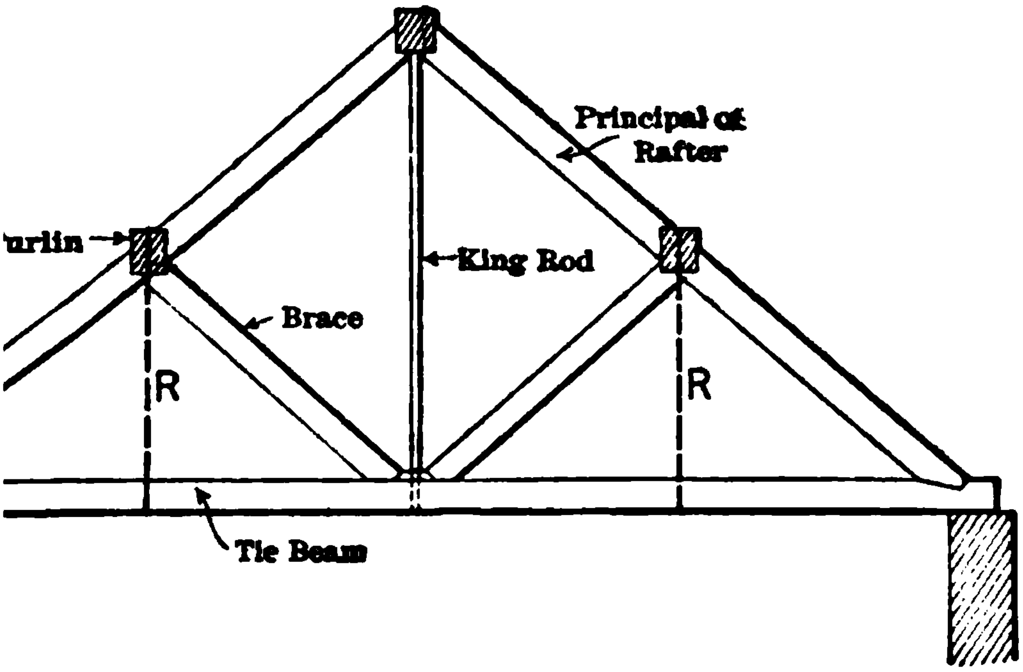
ɪɴɢᴜʟᴀʀ Howe trusses to distinguish them from the standard
rith parallel chords.



ig. 2. King-rod Truss. Spans up to Thirty-six Feet

Truss. The rise of the rafter in any of the trusses, Figs. 1 to
be less than 6 in in 12 in or 26½°; a ⅓ pitch, or a rise of 8 in
ally the most economical. When the span exceeds 36 ft, it is
to cut off the top of the truss as in Fig. 6, which shows the
the ancient queen-post truss. This truss is frequently used
of deck roofs, although it may also be used for a pitched roof
When the top chord is more than 12 ft long, the size of the
considerably reduced by using a center rod and a pair of struts
7. The center rod will be especially needed if the bottom
ı is subject to a bending stress. The center rod should never
, without the braces.

Counters. The truss shown in Fig. 6 differs from those shown in Figs. to 5, in not being composed entirely of triangles and in having a rectangle the middle. Assuming the joints to be pin-connected and without friction,

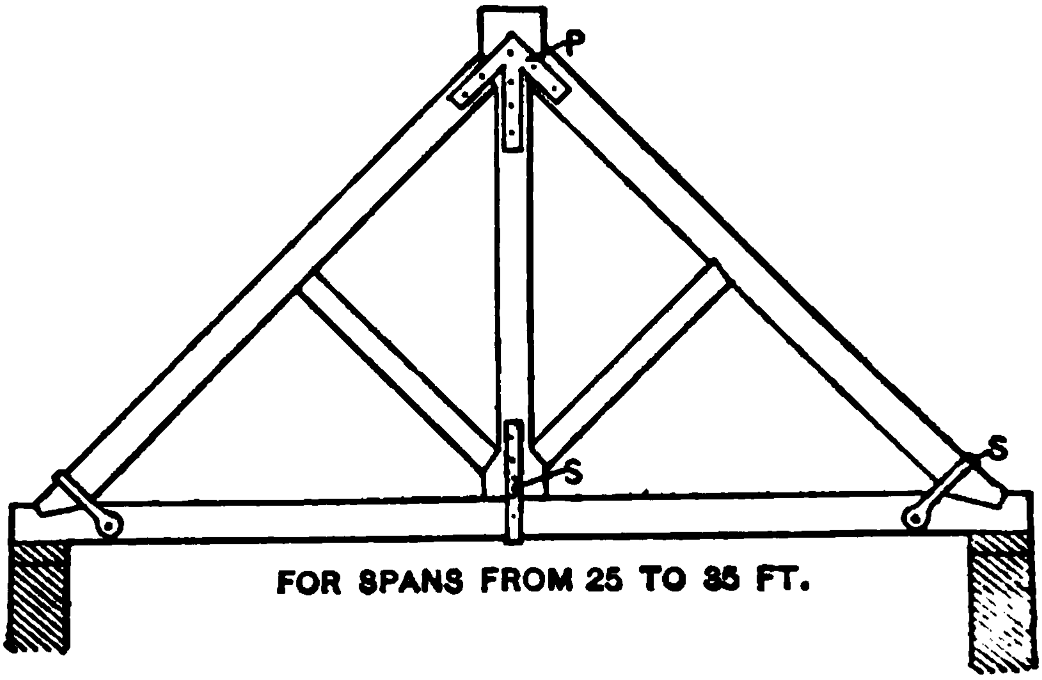


Fig. 3. Modern King-post Truss

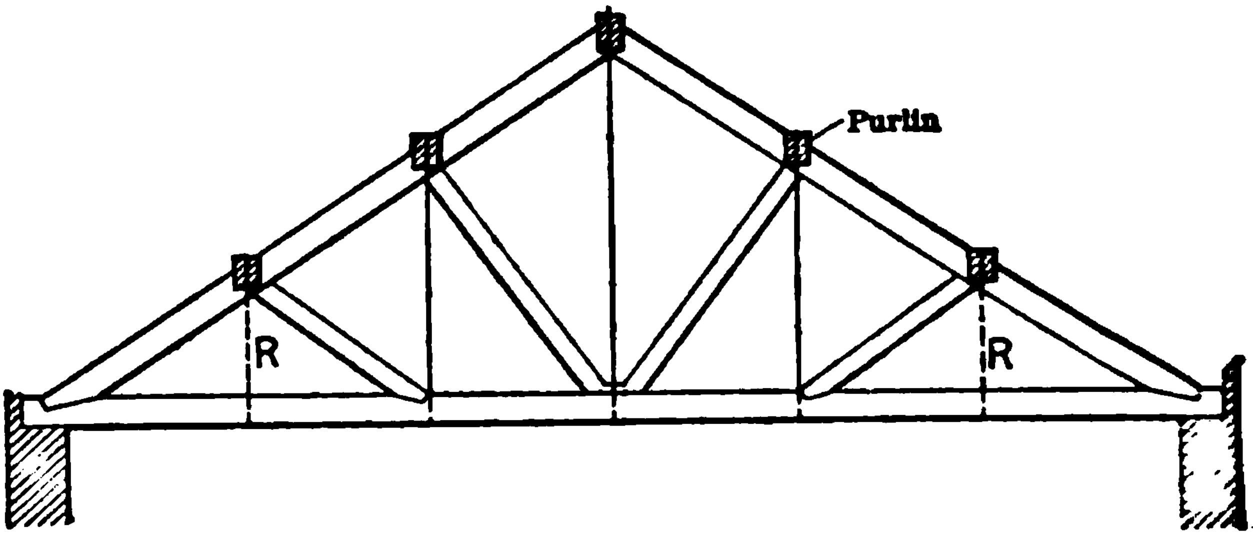

Fig. 4. Six-panel Triangular Howe Truss. Spans from Thirty-six to Fifty Feet

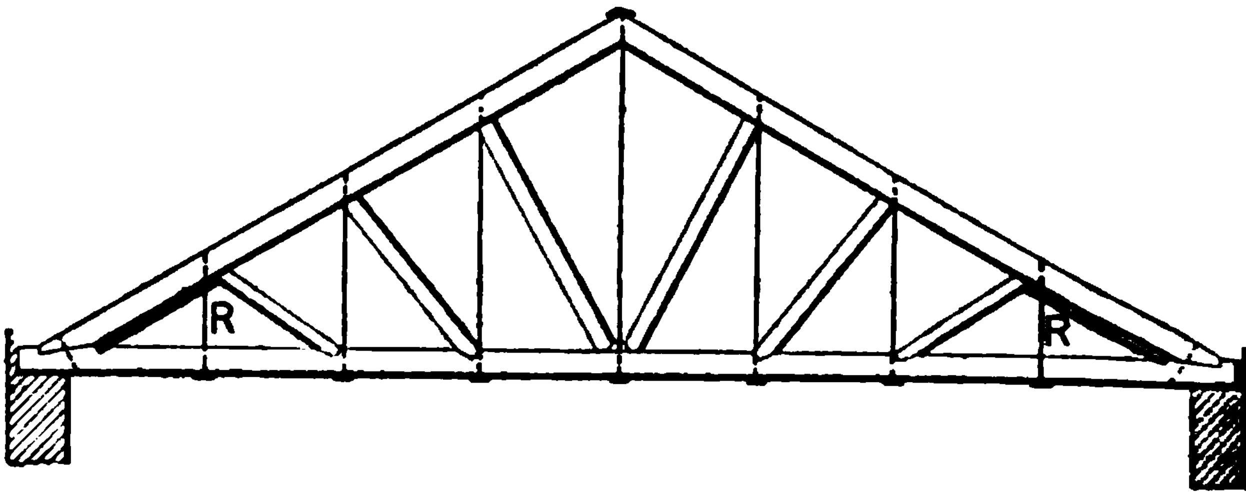

Fig. 5. Eight-panel Triangular Howe Truss. Spans from Forty-eight to Sixty Fe

is evident that a very small inequality in the position or magnitude of the lo ing will cause the failure of the truss since the rectangle will not retain its sh This is easily verified by means of a cardboard model fastened at the jo

eyelets. When the joints at the corners of the rectangle are not :o turn they have a tendency to prevent distortion. When the

wn, the diagonal is in compression and is usually called a If the piece were in tension it would be called a COUNTERTIE.

al Loads. Although roof-trusses of the type shown in Fig. 9, etrical loads, do not theoretically require COUNTERS, it is never-

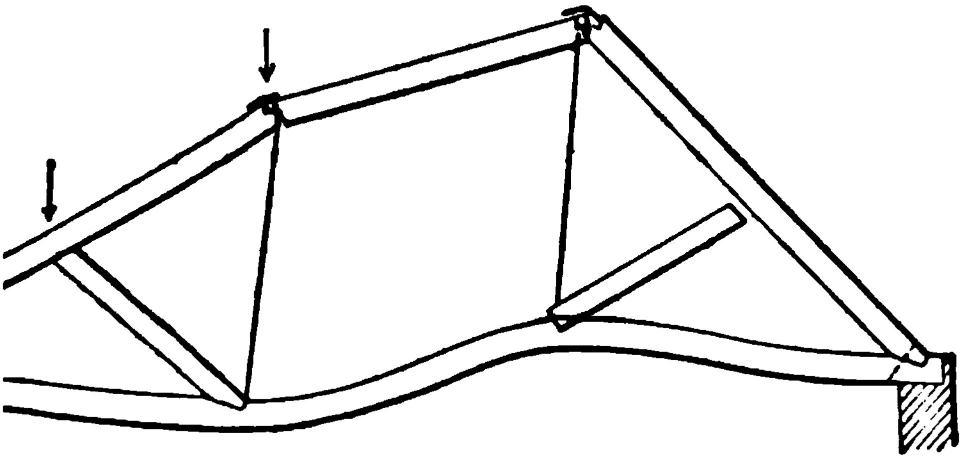

Fig. 8. Distorted Queen-rod Truss

o brace the rectangle along both diagonals to insure stability unsymmetrical loading and to relieve the joints from any latter, which is usually caused by wind, snow and floor-loads.

Reversal of Stresses. In some trusses subjected to different loading different times, the diagonal web-members near the center may be subjected tension for one loading and compression for another loading. In such case

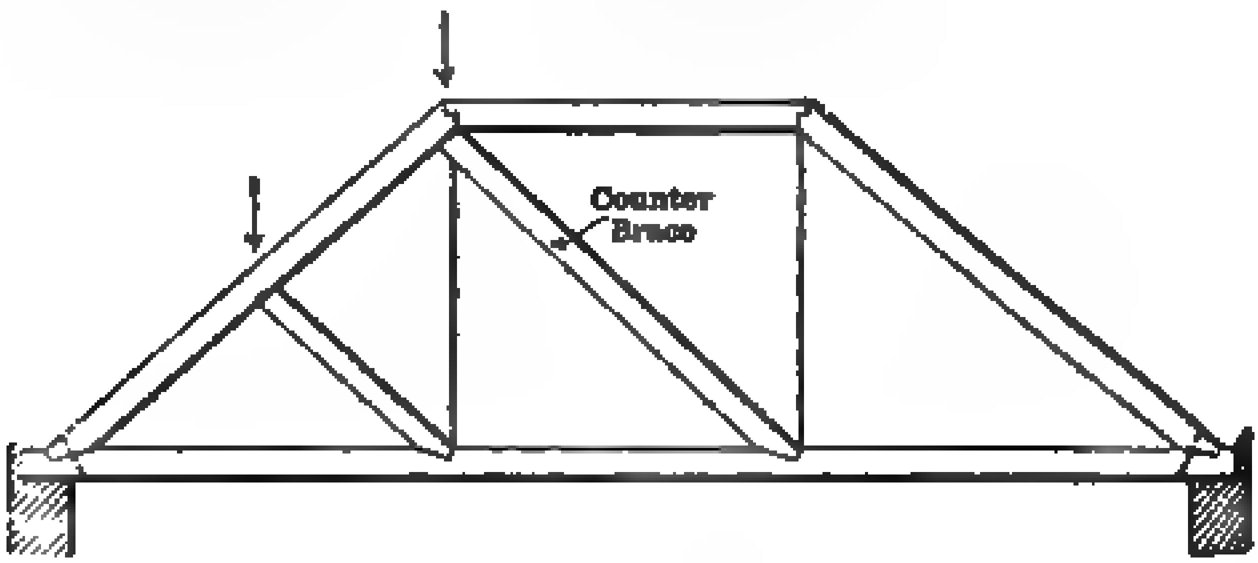

Fig. 9. Counterbraced Queen-rod Truss

is advisable to introduce a member following the other diagonal of the qua lateral containing the member subjected to the two kinds of stress, to assist main member. This piece, also, is called a COUNTERBRACE or COUNTER according to the kind of stress it has to resist. If this is not done, the mem

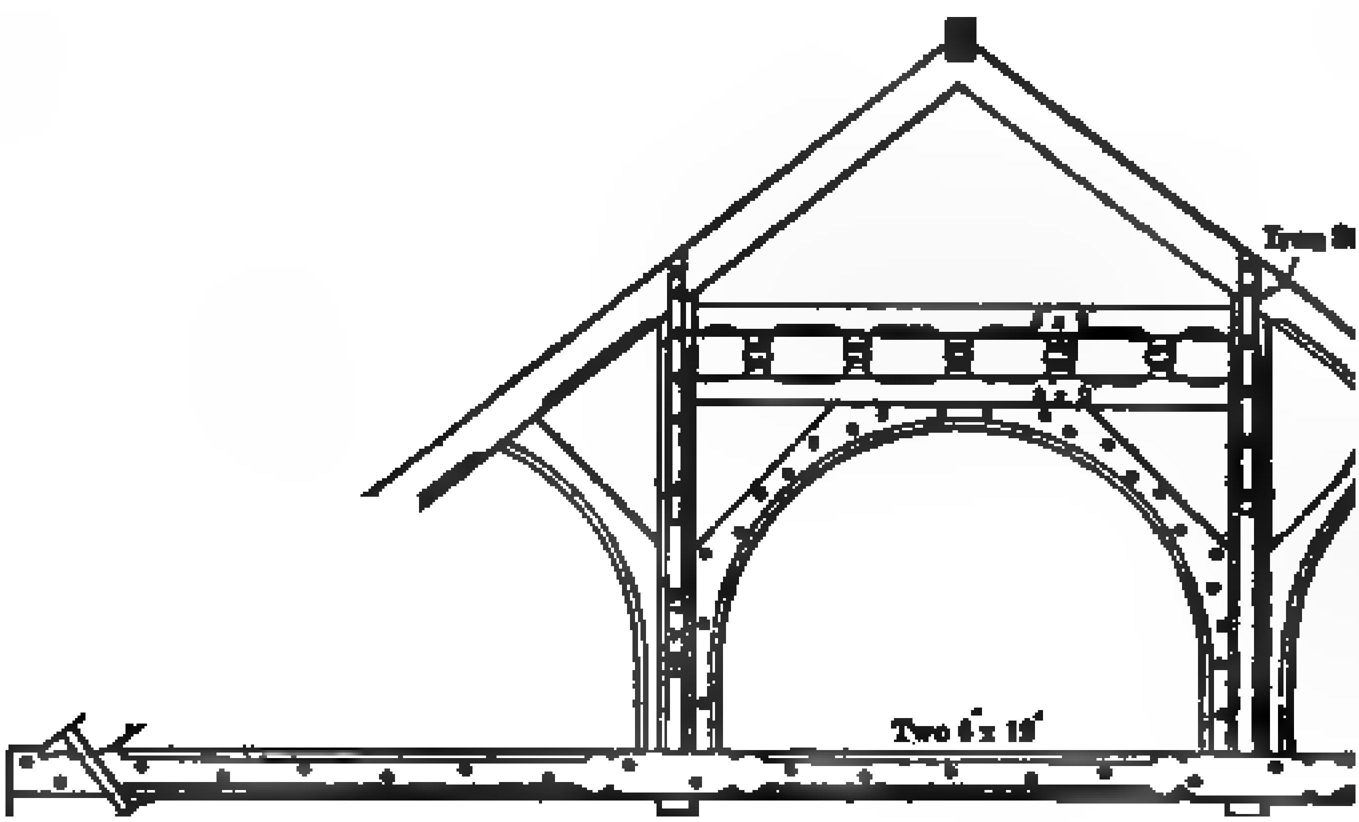

Fig. 10. Queen-post Truss. Massachusetts Charitable Mechanics' Association B ing, Boston, Mass.

which is subjected to two kinds of stress must be designed for both tension compression and the ends connected at the joints to meet the same condi

An Ornamental Queen-Post Truss, supporting a portion of the roof of Massachusetts Charitable Mechanics' Association building in Boston, Mass.,

ſr. William G. Preston, is shown in Fig. 10. The truss-members, ong-leaf yellow pine, were worked from timbers of the dimensions ıs truss wooden members instead of rods are used for the vertical ɔolted and tenoned to the tie-beam and secured to the rafters by The curved ribs take the place of counterbraces.

[1]1. Queen-rod Truss. Museum of Fine Arts, St. Louis, Mo.

Rod Truss from the Museum of Fine Arts, St. Louis, Mo., 'eabody & Stearns, is shown in Fig 11. It supports the floor s of three rods. The truss-rods have nuts and washers below the the threads on the rods are long enough to receive turnbuckles the suspension-rods with the truss. This is generally the best pending a floor from a truss.

's a detail of joint *A* of the 1.

mitted for Special Reasons. truss, sometimes used when it ep the middle part of an attic structions. In building this isable to construct the lower ers of two timbers, thoroughly , as shown. What has been to counterbraces in queen-rod also to this truss, although in continuous rafter aids very esisting distortion from wind-ıat for ordinary construction ɩot exceeding 40 ft it is safe to ıces.

Fig. 11A. Detail of Joint *A*, Fig. 11.

Supporting Common Rafters. Before describing other types ay be well to consider the manner of supporting the common russes. Occasionally it is desirable to span the common rafters russ, but as a general rule it is better construction to support s of large beams or PURLINS which themselves span from truss wn in Fig. 13.

ıe trusses can be designed so that the purlins need not be more t, and very often not more than 6 or 8 ft apart; so that the need not be more than 2 by 4 or 2 by 6 in in cross-section, while be spaced 12, 14, or 16 ft on centers. As a rule a spacing of

about 14 ft for the trusses and of 9 ft 6 in for the purlins is found to be th most economical arrangement. Another advantage in the use of purlins that where they are placed at the truss-joints no bending stresses are develop in the truss-rafters or chords; and hence the latter may be made lighter than

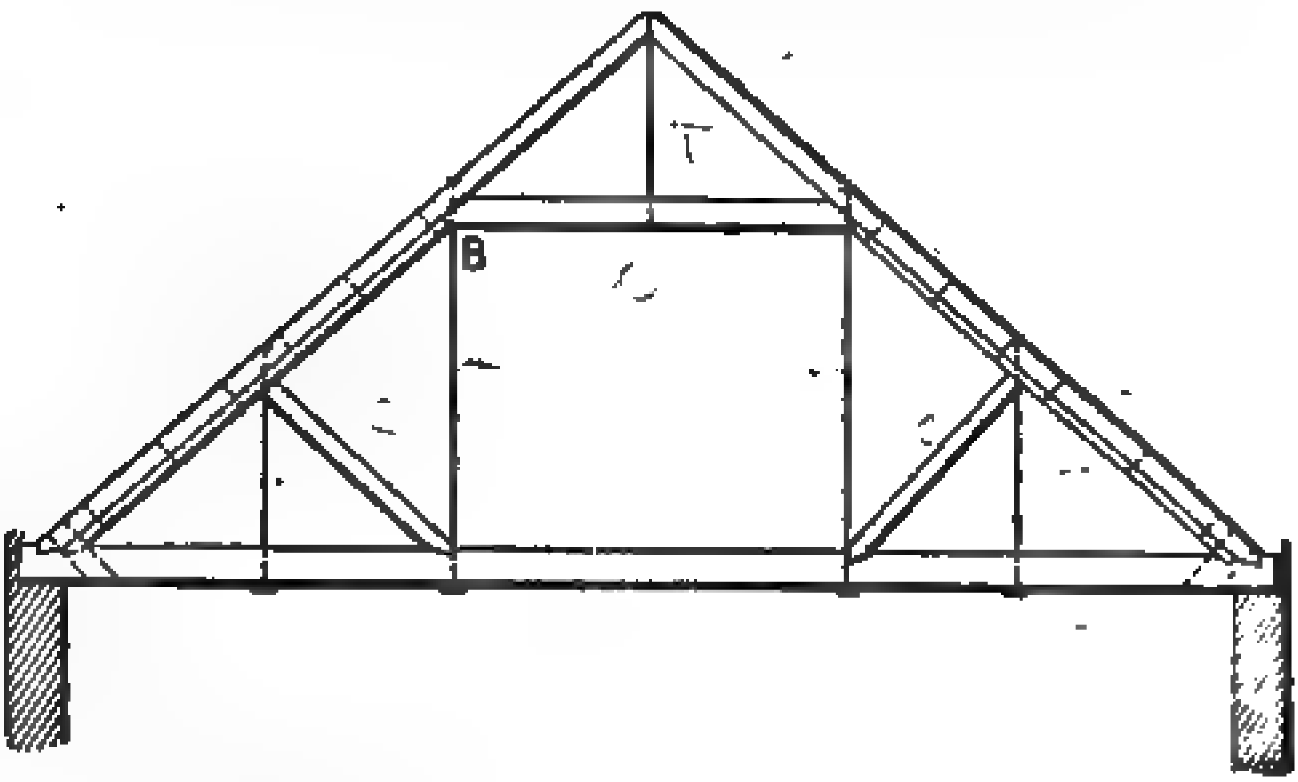

Fig. 12. Queen-rod Truss with Middle Part Clear. Spans up to Forty-two Feet

they supported the common rafters. For wooden trusses of 60 ft or great span, purlins should always be used.

Supports for Purlins. Purlins may be placed with their sides either verti or at right-angles to the plane of the roof, as shown in Figs. 2 and 13. T ends of the purlins m be supported by mea of beam-hangers, de cribed in Chapter XX by double stirrups; 3-in planks bolted a spiked to the sides the trusses, or th may rest on the t chords themselves. T ceiling-joists or flo joists are usually su ported at the sides the tie-beams, as at Fig 13, or simply r on them, as at *B*. Wh they support an at floor it is better to use the latter construction. In the case of SCISSORS TRUSS it is sometimes more economical to support the ceiling-joists by purlins; b when the tie-beams are horizontal it is more economical to use them for t direct support of the ceiling-joists or floor-joists. All chords which supp rafters, ceiling-joists or floor-joists must be designed for bending stresses well as for longitudinal stresses.

Fig. 13. Manner of Supporting Common Rafters and Purlins

Trusses with Horizontal Chords. For the support of flat roofs, with without a ceiling below, and for conditions such that horizontal trusses

types shown in Figs. 14 to 17 are undoubtedly the most satis-
den construction, when the span does not exceed 80 ft; and
ies where the cost of iron rods is relatively great, it is as econom-
this work the name HOWE TRUSS is given to this type, as it is
of the Howe bridge-truss to building-construction; and the
L TRUSS is also sometimes used. Trusses of this type can be

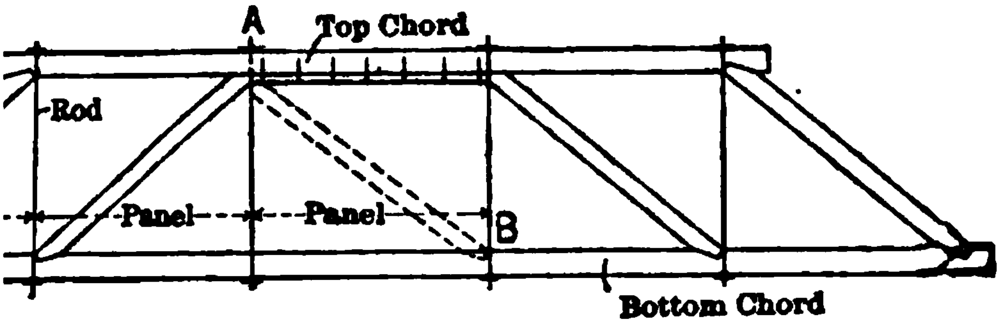

Fig. 14. Five-panel Howe Truss

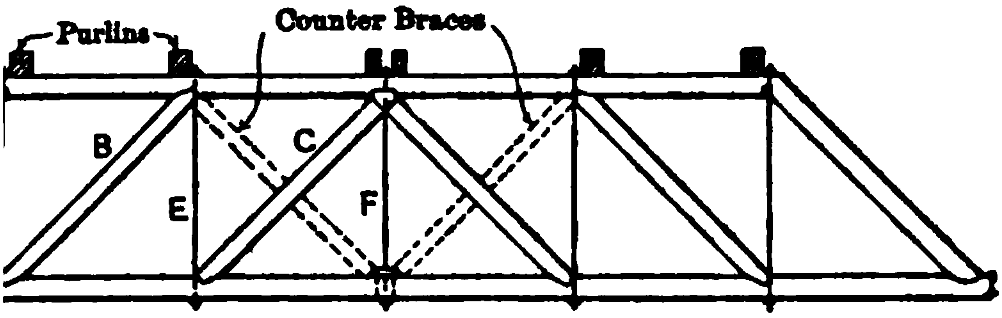

Fig. 15. Six-panel Howe Truss

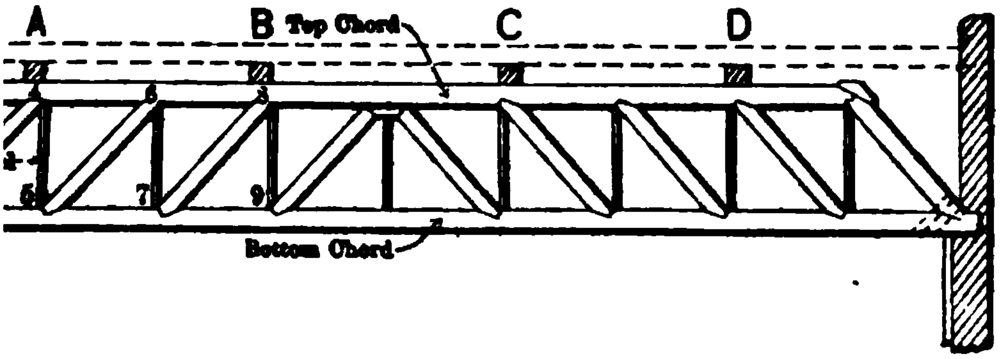

Fig. 16. Ten-panel Howe Truss

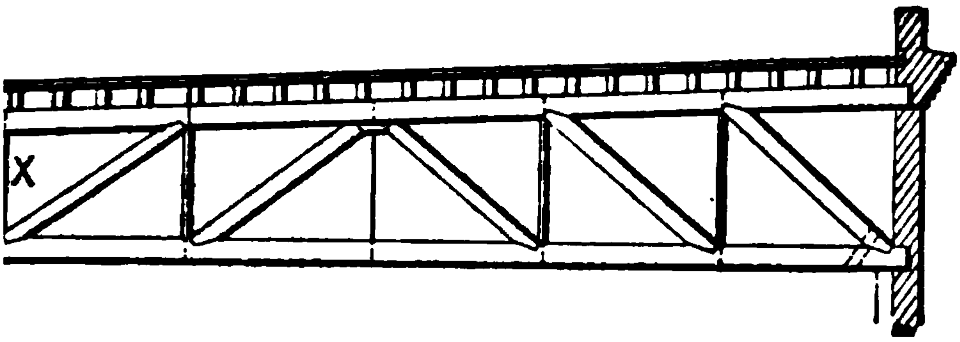

17. Six-panel Howe Truss with Top Chord Inclined

gh for spans up to 150 ft; but when the span exceeds 100 ft
per to use a steel truss of the PRATT TYPE in which the verti-
ssion and the diagonals in tension. When a Howe truss is
tudinal direction of a flat roof, the top chord may be given
he roof itself, so as to support the rafters without the blocking
7. For deck roofs the top chord may be inclined upwards
r deck-ridge, to conform to the shape of the roof, as shown in

Fig. 18. For deck roofs and mansard roofs the middle panels should ha counterbraces, as shown in Fig. 18, to resist the wind-pressure against th sides of the roof and any unequal distribution of snow.

Height of a Howe Truss. The height of the truss, measured from cent to center of the chords, should never be less than one-ninth the span f spans up to 36 ft, nor less than one-tenth the span for spans from 36 to 80 f

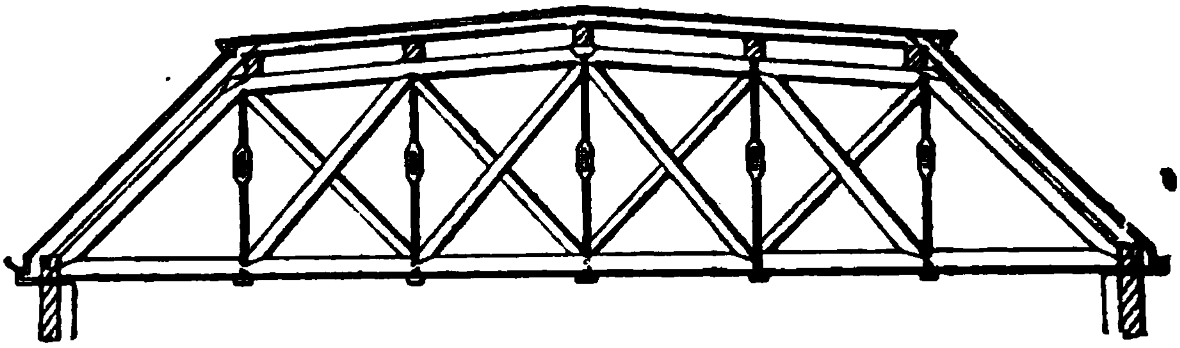

Fig. 18. Howe Truss for Deck Roofs

As a general rule a height of from one-seventh to one-sixth the span will most economical. When the top chord is inclined, as in Fig. 17, the height X, that is, at the shortest rod, should not be less than the limit given above.

Number of Panels in a Howe Truss. In this type of truss a PANEL the space between two adjacent rods or between an outer rod and the en joint (Fig. 14). As a rule, the number of panels should be such that the dia onals will have an inclination of from 36° to 60°, an inclination of about 4 being the most economical. It is not material whether there is an even or odd number of panels. If the position of one or more of the purlins is fix by some special requirement, then the panels should be so arranged that t upper joints come under the purlins, and the inclination of none of the diagon is less than 36°. Although it is generally better to have the truss symmetri about the center, it is not absolutely necessary; nor is it necessary to make t panels of uniform width. When the truss is not symmetrically loaded, howev it may be necessary to reverse the brace in one of the center panels. This po is considered in Chapter XXVII, page 1102, under the subject of UNSYMMETRI CALLY LOADED TRUSSES.

Counterbraces in a Howe Truss. If there is any chance of the tr being more heavily loaded on one side of the center than on the other, COUNTER BRACES, that is, braces inclined in the opposite direction from that of the regu braces, should be placed in the center panels, as shown by the dotted lines Fig. 15. If the truss is deep and the diagonals long it is economical to count brace each panel as shown in Fig. 18. If the number of panels is odd, as sho in Fig. 14, no diagonals are required in the middle panel when the braces and loading are symmetrical; but it is good practice to cross-brace this panel provide for any accidental unsymmetrical loading.

Spacing of Trusses. The most economical spacing, center to center, of trusses, all things considered, is usually from 12 to 16 ft for spans up to 60 and from 14 to 20 ft for greater spans.

Spacing of Purlins. Purlins should always be placed as near the tr joints as possible; they should also be spaced so as to effect the greatest econo in rafter-construction. Their spacing, therefore, determines, to a large ext the number of panels. When the height of the truss is not more than one-ni or one-tenth the span, it is often more economical to place a purlin over ev other joint, as in Fig. 16.

	1	10×12	10×14	10×12	10×8	10×6			

Bearing on Wall or Post. The point where the axial lines of the e brace and of the tie-beam intersect should always come over the support, a if possible over the axis of the supporting wall or post.

Stresses in a Howe Truss. The stresses in the chords are always greate at the middle of a truss, diminishing towards the supports, while the stresses i the rods and diagonals are greatest at the ends of a truss.

Table of Dimensions for a Howe Truss. In SYMMETRICAL TRUSS having panels of uniform width and uniformly loaded, the stresses in the diffe ent members are proportional to the span, number of panels, height of trus spacing of trusses and load per square foot. It is therefore possible to prepa tables giving the proper dimensions of the members of such trusses. Table gives the dimensions for six-panel trusses for heights of one-sixth and one-eight the span and for three different spacings. These dimensions are for a fl roof covered with tin, sheet iron, or composition; a snow-load of 16 lb per sq f equivalent to about 24 in of light, dry snow; also for a lath-and-plaster ceilin supported by the bottom chord. The chords and braces are of Norway pin and the rods of wrought iron. These dimensions apply only when the rafte

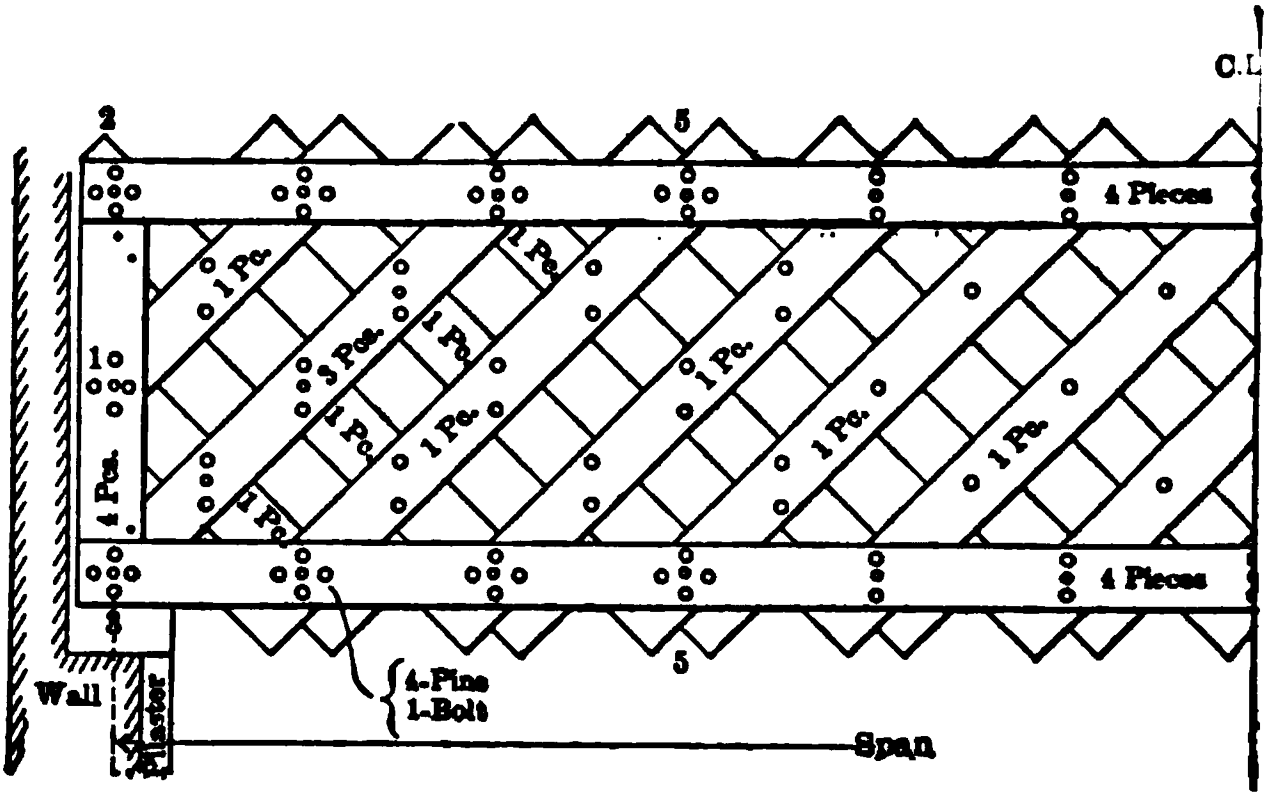

Fig. 19. Lattice Truss

are supported on purlins placed at the upper joints, as in Figs. 15 and 16 When the rafters rest on the top chord, as in Fig. 17, the dimensions o the latter must be increased and special calculations made for it. The dimen sions given in the table may be used for trusses of greater height than tho given, but not for trusses of less height, as the less the height the greater th stresses in the chords and braces. When the conditions of load, span, heigh and spacing are not exactly as given above and in the table, the stresses shoul be determined and the members of the truss proportioned accordingly; bu even in such cases the table will serve somewhat as a check on the com putations.

Lattice Trusses. In localities where timber is not expensive the LATTIC TRUSS (Fig. 19) is often found economical for supporting flat roofs. This typ of truss was invented for bridges by Ithiel Towne in 1820 and a large number o

; have been constructed with trusses of this type, some of which now (1915) in New England. The principal objections to the ıdency to twist sidewise, like a thin board on edge, its flexibility lane and the difficulty of getting sufficient bearing material at As indicated in Fig. 19, the truss is composed of top and bottom parallel, connected by lattice bracing. The chords are com-lanks, two being on one side and two on the opposite side of the bottom chord the planks should be as long as can be obtained o that no two splices are near the same point. The available om chord to resist tension is the area of three planks less the area oints by the connecting pins or bolts. Each member of the web gle plank arranged as shown in Fig. 19. The braces are inclined ıbout 45° and usually three sets are sufficient, as shown in the nnections are best made with American-locust pins, which give eas without much extra weight. Modern construction employs : expensive and add considerable weight. There should be at

al Section of
in Fig. 19

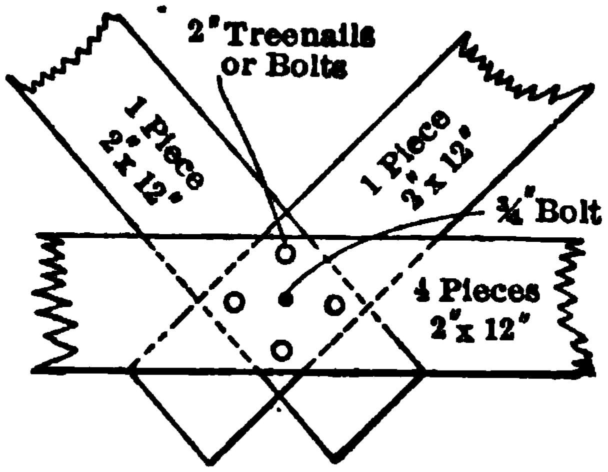

Fig. 21. Lower Joint 5 of Truss Shown in Fig. 19

each connection, if the planks are wide enough to permit, and t the chord-joints. Since about one-half the web planks resist the web projects beyond the chord at least 4 in to provide dinal shearing area. The ends are reinforced by vertical tim-:en the chords and each set of diagonals is thoroughly fastened

In some cases it is necessary to add timbers on the outside d them down to the lower face of the bottom chords to relieve bearing-stresses where they rest on the supports. The methods he stresses in this truss are considered in Chapter XXVII, 91. Figs. 20 and 21 show details of this lattice truss.

ses with Raised Bottom Chords. All of the trusses thus e horizontal bottom chords; and this construction is the most as the most economical and should be used whenever condi-ssitate a greater height of ceiling. In roofing churches, public ceilings are often desirable as they increase the general height t increasing the height of its side walls.

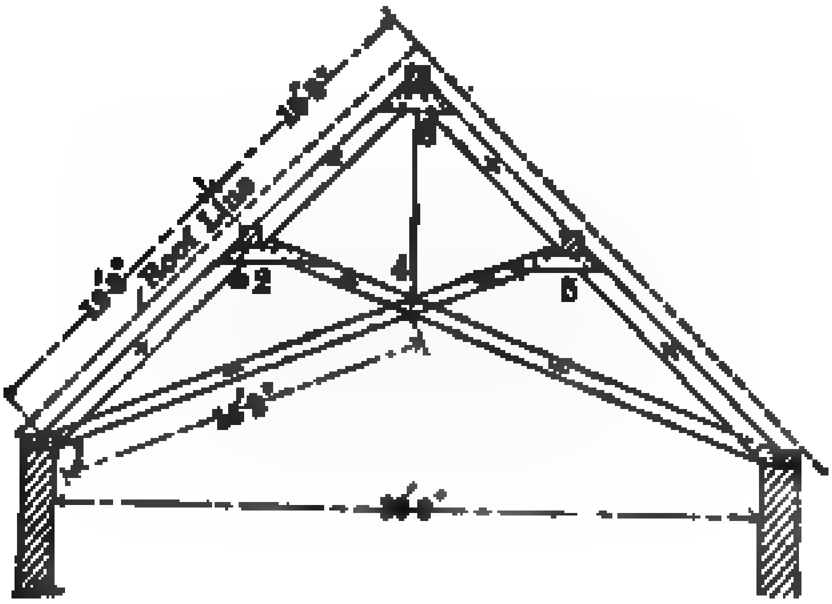
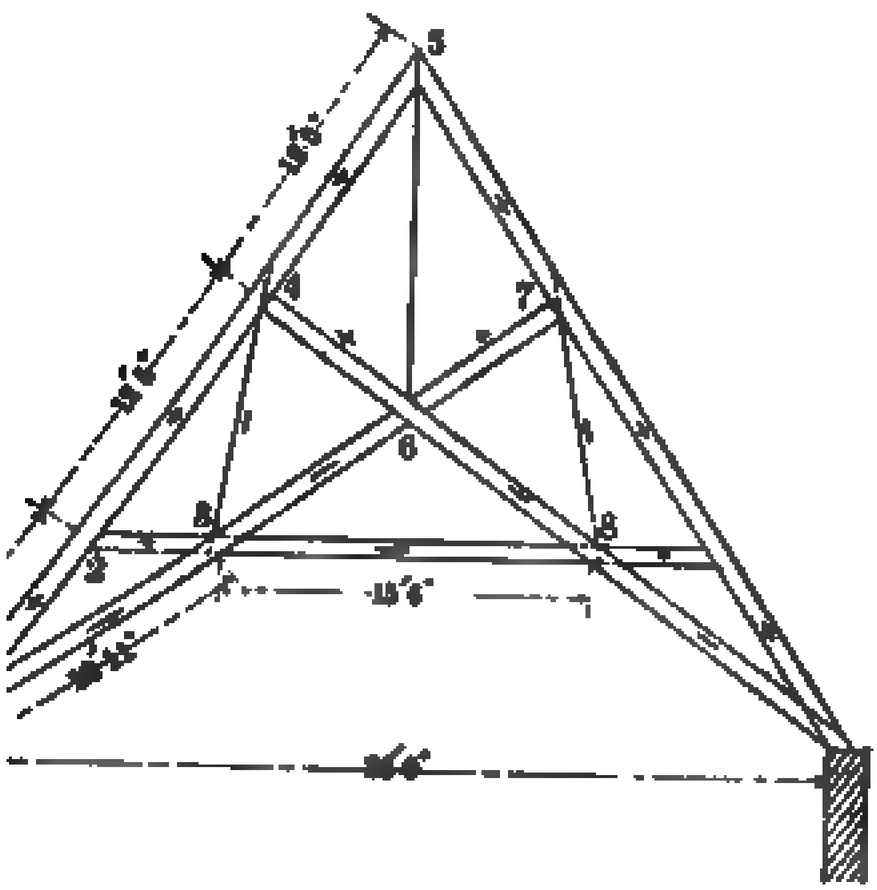
Note. All joints should be thoroughly spiked and packing blocks used where necessary. When treenails are used each chord-joint should have in addition one ¾-in bolt as shown in Fig. 21.

Scissors Trusses. For the roofs described in the preceding paragraph some form of the SCISSORS TRUSS, so named from its resemblance to a pair of scissors, is most often used. When correctly designed, with members of the proper size, and with joints carefully proportioned to the stresses, it is a very good truss for supporting roofs over halls and churches, up to a span of 48 ft; but for greater spans it should be used with caution, as the stresses become very great and the joints difficult to make. Figs. 22 to 27 show different forms of this truss and modifications of it adapted to different spans and roof-pitches. None of these trusses exerts a large horizontal thrust if the members are of ample size and the joints properly made. The members having a plus sign e



g. 22. Simple Scissors Truss. Spans up to Thirty Feet

. 23. Scissors Truss. Spans Exceeding Thirty Feet



Truss. For Steep Roofs. (See Chapter XXVIII, Figs. 18 and 19)

or close to them are in COMPRESSION, while those having a minus sign are TENSION. The determination of the actual HORIZONTAL THRUST is consider on pages 1085–1087. The members indicated by a single line should be rod

Fig. 25. Modified Scissors Truss. For Medium Pitch. (See, also, Chapter XXVI Figs. 18 and 19)

except in the case of bottom chords. Fig. 22 shows the simplest form of t SCISSORS TRUSS, which is suitable for spans up to 30 ft. When the span excee 30 ft, it is more economical to use two purlins on each side to support the co

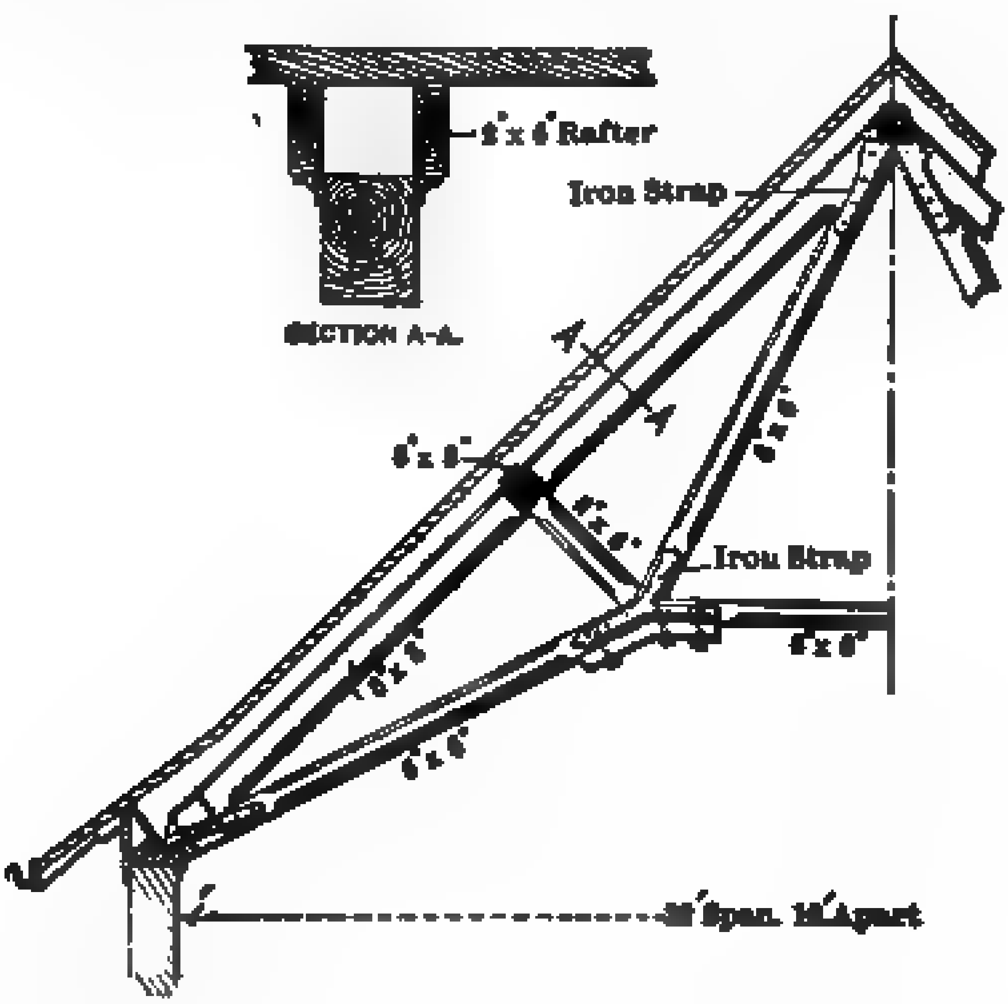


Fig. 26. Finished Cambered Truss. (See, also, Chapter XXVIII, Figs. 18 and 19)

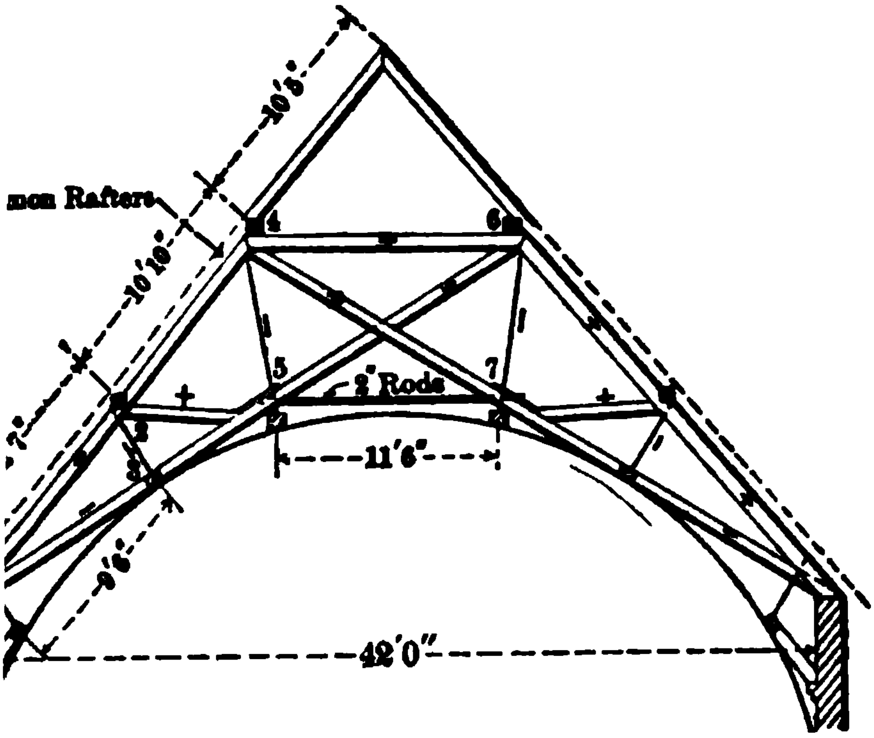
mon rafters; and additional supports from the bottom chords are general required, calling for additional rods and braces, as shown in Fig. 23. For steep roof the arrangement shown in Fig 24 is generally the best, and for

t shown in Fig 25, in which the scissors pieces do not cross nor Fig. 26 shows a finished truss, built on somewhat the same lines wn in Fig. 25 but with only one purlin. This truss can hardly a scissors truss but is shown here for convenience. It is really as that of the truss shown in Fig. 33. . The truss shown in Fig.) that shown in Fig. 24, with the peak cut off, but for spans



Scissors Truss. Spans Exceeding Thirty-six Feet. (See, also, Chapter XXVIII, Figs. 18, 19 and 20)

is more economical. It can also be used where the roof is is form it is better to use ceiling-purlins to support the ceiling-n the latter from truss to truss.

m Trusses. Two of the principal characteristics of the Gothic ure are the relatively elaborate ornamentation of structural posure to view of the construction of a building as a whole. rch and steep roof were developed the roof-truss became an in the ornamentation as well as in the construction of Gothic s. The trusses of this period were built almost entirely of lly of very heavy timbers, to give the appearance of great the most common types of these Gothic trusses, and also ital, was the HAMMER-BEAM truss, still often used in churches othic style. Figs. 28 and 29 show early English forms of this s its name from the horizontal beam H, called the HAMMER-of the principal rafter. In the more ornamental trusses this s usually carved to represent royal personages or angels. er in principle from those thus far described, in having no no substitute for one. In fact the trusses shown in Figs. come within the scope of the definition of a TRUSS given at the chapter. Although the rafters or principals are connected truss by a short COLLAR-BEAM, this offers but little resistance f the rafters to spread at their lower ends; and hence the er upon the transverse strength of the rafters or upon the alls to keep it intact and, generally, upon both. This form of t of an ARCH, as vertical loads produce inclined reactions at the alls and churches of the Gothic period the walls were generally

very thick and usually reinforced on the outside by BUTTRESSES built agai them and directly opposite the roof-trusses. In most cases such a wall posses sufficient stability to withstand the THRUST of the truss, and hence the bott chord may be dispensed with; but in a wooden building the walls, unless t at the top, offer no resistance whatever to being thrust out and hence, in s buildings, no truss which exerts an outward thrust on the walls should be u

Fig. 28. Hammer-beam Truss. Early English Form

It is therefore generally impracticable to use a hammer-beam truss in a woo building. Where these trusses are used, the CEILING is generally formed of matc sheathing, nailed to the under side of the JACK-RAFTERS between the pur thus allowing the latter to be seen. The purlins are generally decorated, FALSE RIBS are often placed vertically between them, to divide the ceiling PANELS. The main rafters should be made very large to prevent them breaking at the point A, Figs. 28 and 29.

First Church, Boston, Mass. An excellent example of a truss adapted to modern conditions is shown in Fig. 30, which half of one of the trusses designed by Ware & Van Brunt, for

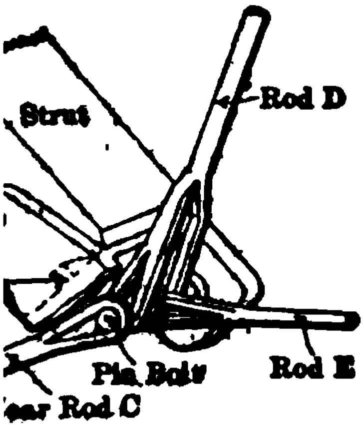
form and when securely bolted together at all the joints can be design
to exert very little thrust on the walls. The rafters and cross-tie are
formed of two pieces of timber, separated but bolted together, the
upright members passing between these pieces. The hammer-beams are

ngels. The action of the stresses in hammer-beam trusses is
iapter XXVII, pages 1087 to 1089.

usses with Iron Ties. Where there is no ceiling beneath the
lesirable to make the trusses as light in appearance as possible,



Detail of Joint B, Fig. 28

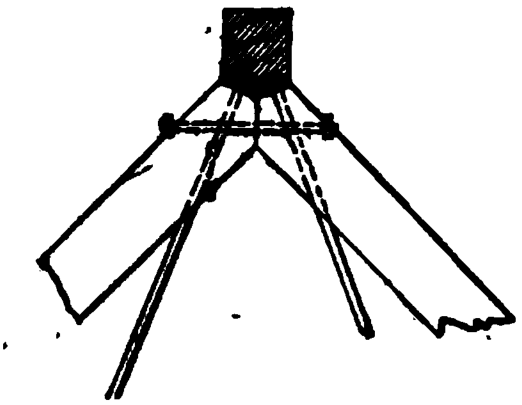


Fig. 33a. Alternate Detail of Joint at Ridge, Fig. 33

steel rods may be used for the ties, and the wooden rafter-
ts retained. For moderate spans such trusses are cheaper than
nd where the rafters and purlins are of wood they are about as
and 34 show forms of trusses well adapted to many roofs. The
n in Fig. 34 are for yellow-pine or Douglas-fir timber and wrought-

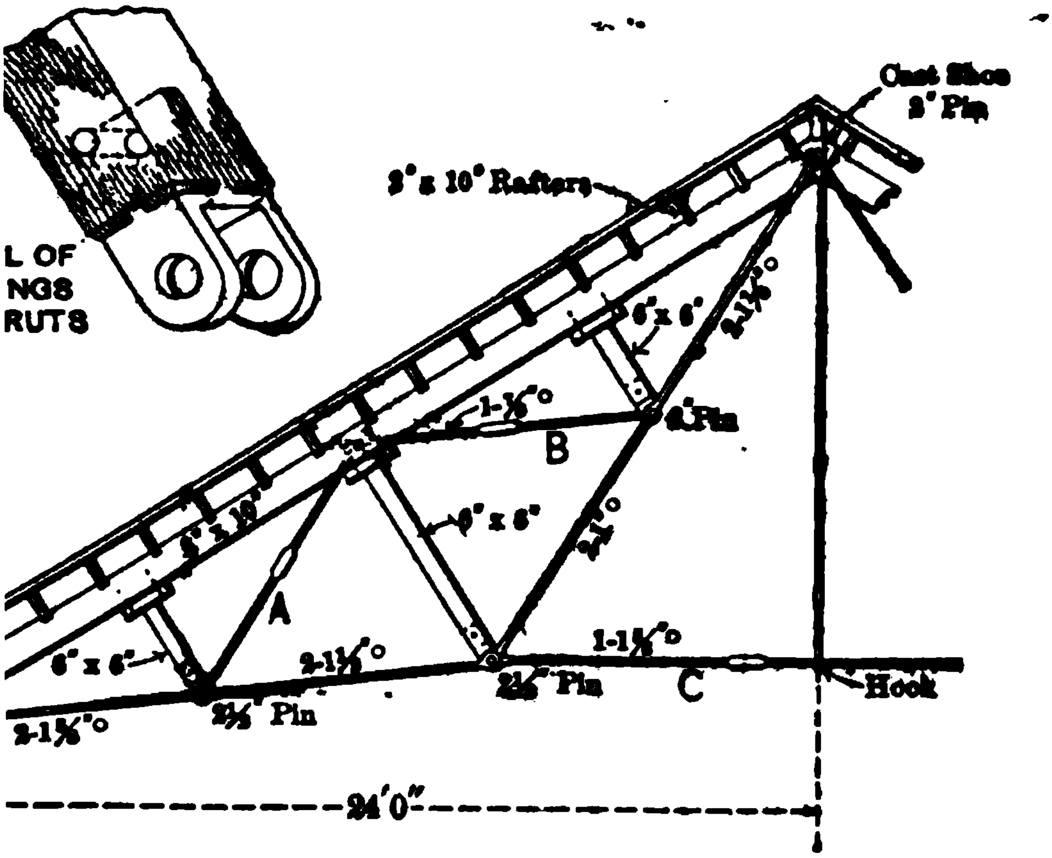

Fig. 34. Wooden Truss with Iron Ties

re ample for a slate roof, the trusses being spaced from 12 to
. Trusses of the form shown in Fig. 33 are sometimes made
C and D continuous. They should not be made in this way,
the entire rod is proportioned for the stress in C, as this stress
that in D. The best construction for the joint B is illustrated

in Fig. 33A, which shows a CAST-IRON SHOE fitted to the end of the strut t receive the pin. For the truss shown in Fig. 34, a shoe made as shown in th detail drawing makes a better connection for the rods, two of the latter bein placed outside of the brackets and three between them. For a truss with single strut, a TURNBUCKLE on the rod E serves to tighten the rods. Whe there are three struts, the should be five turnbuckles, in Fig. 34. A cast-iron sho should be made to receive th foot of the rafter and the ro secured to a pin passed throug shoe and rafter. At the ape also, of the truss shown in Fi 34, there should be castings t receive the ends of the rafter and pins for the tie-bars. Th apex-joint of the truss (Fi 33) may be made either b crossing the rods through CAST WASHER, or as shown i Fig. 33B. The pins at th joints should be computed fo shear, bearing and flexur More modern construction r places the cast iron shown with STEEL PLATES and PINS. When a hamme beam truss is to be supported on a clerestory-wall which is not very thi nor braced from the outside, a truss of the form shown in Fig. 35 may b used to advantage. It has the appearance of a hammer-beam truss and wh placed over a high nave the effect of the rods is not objectionable. The tie-rods should extend through the hammer-beams to their outer ends.

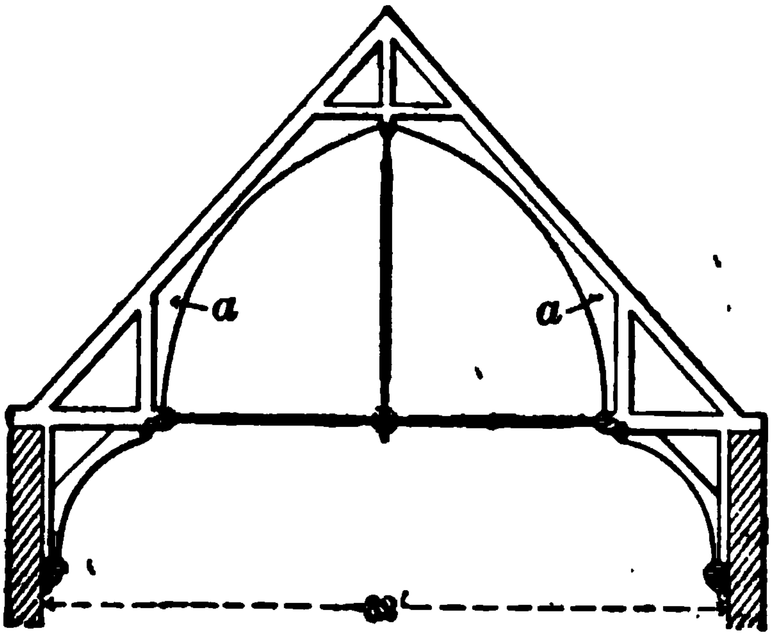

Fig. 35. Hammer-beam Truss for Grace Chapel, New York City

Truss for Grace Chapel, New York City. The CURVED RIBS *a*, *a*, Fig. 35, have a tendency to bend at their smallest section and BRACES under the hammer-beams are necessary to prevent vertical deflection in the latter. A truss similar to this was used in Grace Chapel, New York City.

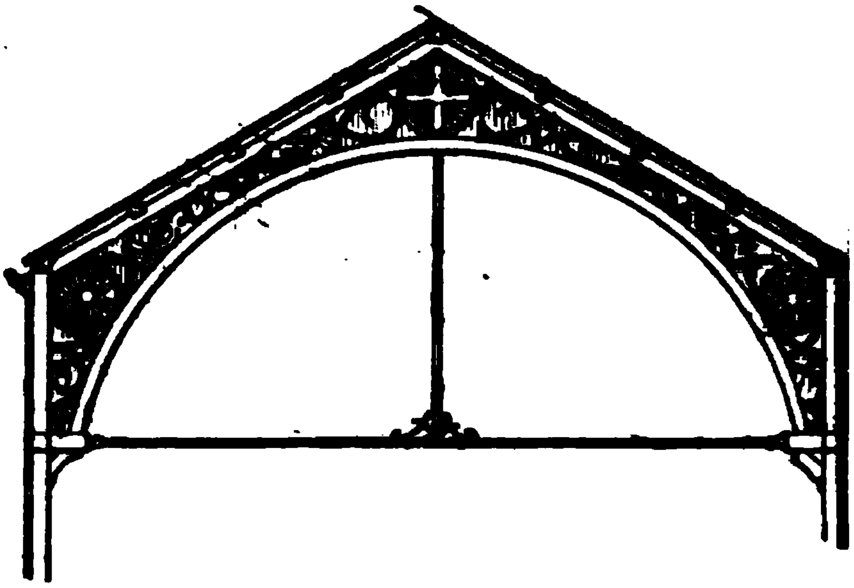

Fig. 36. Truss for Metropolitan Concert Hall, New Yo City

Truss for Metropolitan Concert-Hall, New York City. Fig. 36 sho a form of truss used to support the roof of the Metropolitan Concert-Hall, Ne York City, George B. Post, architect. The span is about 54 ft and the propo tions are about as shown. The arch between rafters and raised rib is orn mented with sawed work and the truss has a very light and airy appearan The tie-rod is kept from sagging by a vertical rod from the crown of th arch.

rched Ribs with Iron or Steel Ties. For roofing large halls SEGMENTAL TIMBER ARCH, with an iron or steel tie to take up the ust, is about the cheapest construction, especially where there is e supported. Figs. 37 and 38 are good examples of this form of

a TRIANGULAR PRATT TRUSS as the web is composed of verticals in compressi
and diagonals in tension. This truss is not as economical as the FINK TRU
except when the inclination of the rafter is less than ¼ pitch. This is
account of the great length of the web-members in compression. In designi

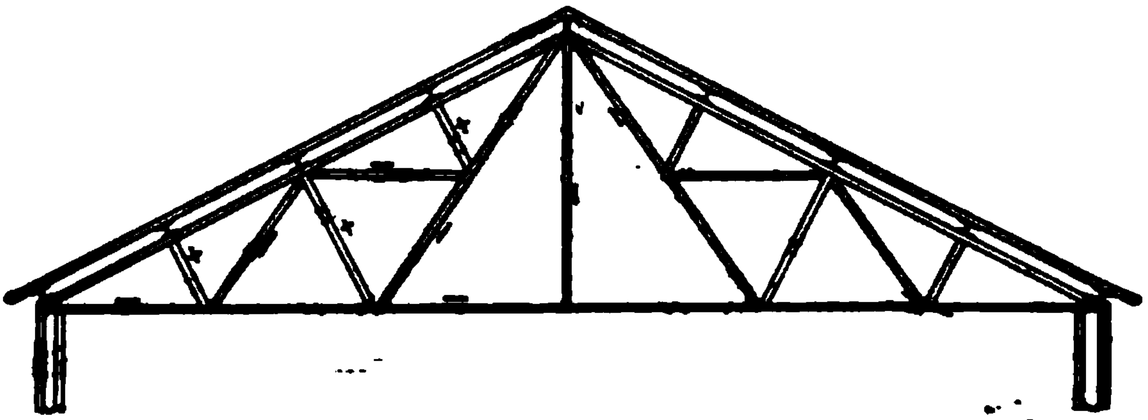

Fig. 48. Fink Truss. Spans from Forty to Eighty Feet

steel trusses it is desirable to have as many members, and especially as m
long members, in tension as possible, as a given weight of steel resists a m
greater stress when in tension than when in compression. The great econo
of FINK TRUSSES and FAN TRUSSES lies in the fact that most of the memb

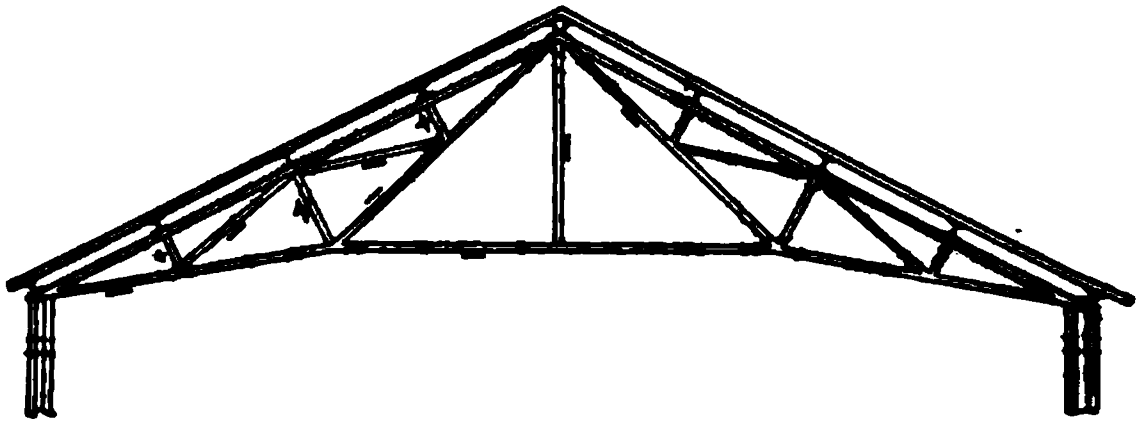

Fig. 49. French Truss. Spans from Forty to Eighty Feet

are in tension and the struts are short. By comparing Figs. 50 and 51,
seen that the inner strut in Fig. 50 is only one-half as long as the strut in
51. If the roof is hipped it is desirable to have vertical members in the
trusses to receive the short trusses or TRUSSED PURLINS.

nk and Fan Trusses. The DEPTH of these trus
y determined by the roofing-material. Thus slate sho

e placed not more than 8 ft apart; and if the roof
secured to the purlins, the purlins should be not
henever the purlins are more than 4 ft apart th
s-joints to prevent large bending-stresses in the

The spacing of the purlins, therefore, generally determines the number of pan in each half of the truss. For this reason also, the same form of truss may required for spans of 40 and 80 ft; but of course the members will not be heavy in the 40-ft truss as in the one with greater span. Most of the trus shown in Figs. 45 to 55 are drawn from executed designs and give a go idea of the most economical division for different spans.

Truss over Car-Barn, Newark, N. J. When stresses due to flexure developed in the truss-rafters, that is, when they are loaded between the joi

rm a part of the truss proper, but are merely a framework to

support the elevated roof, and in drawing the stress-diagram for the verti loads they would be omitted.

In the issues of the Engineering Record given in Table III may be found scriptions and illustrations of several types of roof-trusses, including the fo described above.

Fink Trusses with Pin-Joints. The use of PIN-JOINTS in ordinary r trusses has practically been abandoned, even for long-span heavy trusses. the Engineering Record of March 12, 1892, there is a description of a Fink tr with pin-joints. The truss is heavy and is built entirely of rolled metal. T tension-members are 5, 6 and 7-in eye-bars. The span is about 105 ft.

Trusses for Flat Roofs. For supporting flat roofs or roofs having a not exceeding 1 in to the foot, one of the types shown in Figs. 56 to 60 will g

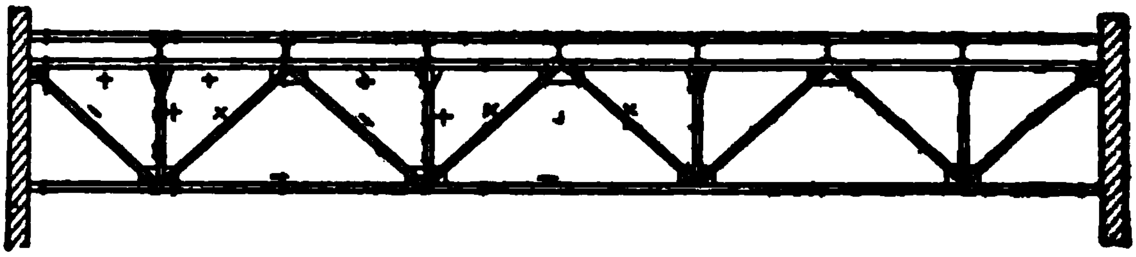

Fig. 56. Warren Truss with Verticals. Span Fifty-six Feet

erally be found economical, the choice of the particular type depending somew on the span and on whether the truss is supported by columns or by brick stone walls. For spans up to about 50 ft, either of the forms shown in Figs or 57 answer all practical requirements. The truss shown in Fig. 56 is inten to be used where the slope of the roof is at right-angles to the truss. It can built, however, with the top chord inclined as in Fig. 57. The end-diago in Fig. 56 are in tension, while in Fig. 57 they are in compression. The porti of the lower chord between the end-joints and the walls (Fig. 56) have no st

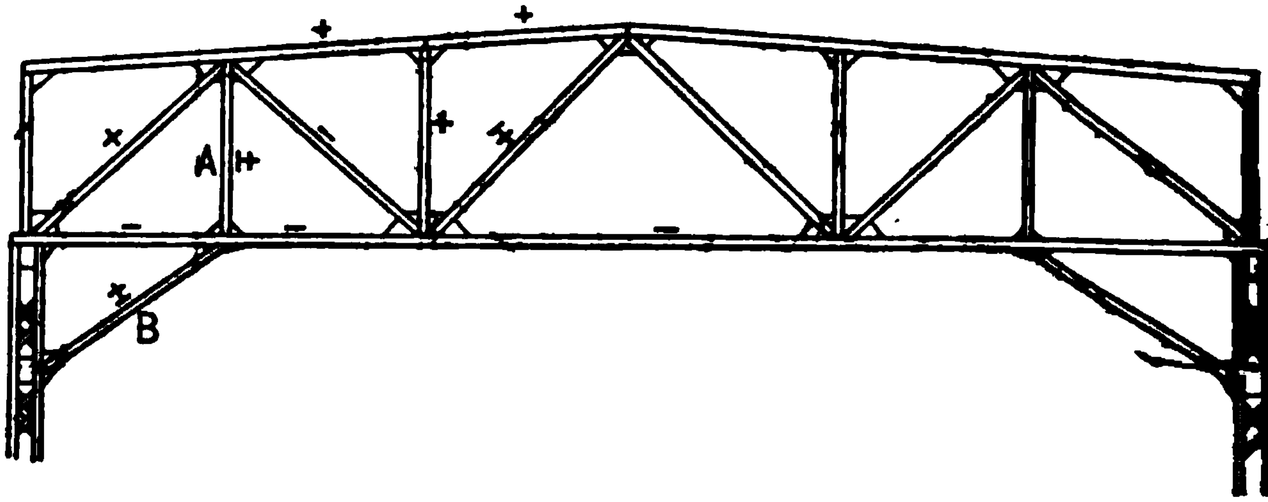

Fig. 57. Warren Truss with Verticals and Knee-braces. Spans from Thirty t Fifty Feet

from the roof-load, but are put in to add rigidity to the construction as a wh In trusses supported by brick walls this type is preferable to that shown in Fig while the latter is more suitable when the roof is supported by columns. vertical *A*, Fig. 57, is inserted to receive the tension or compression from *B*, and has no stress from the roof-loads.

Double Warren Truss. The truss shown in Fig. 58 is known as a DOU WARREN TRUSS, and is desirable where it is important to make the truss shallow as practicable. It can be built with light members, and is a very

specially suitable for roofs supported by steel columns. Fig. 58 a truss in actual use. The member in the middle indicated by the ould never be omitted, although examples may be found where it included. Fig. 59, also, represents a roof-truss which was con- a span of 57 ft and supported by steel columns. The entire load s transmitted to the columns at the intersection of the diagonals

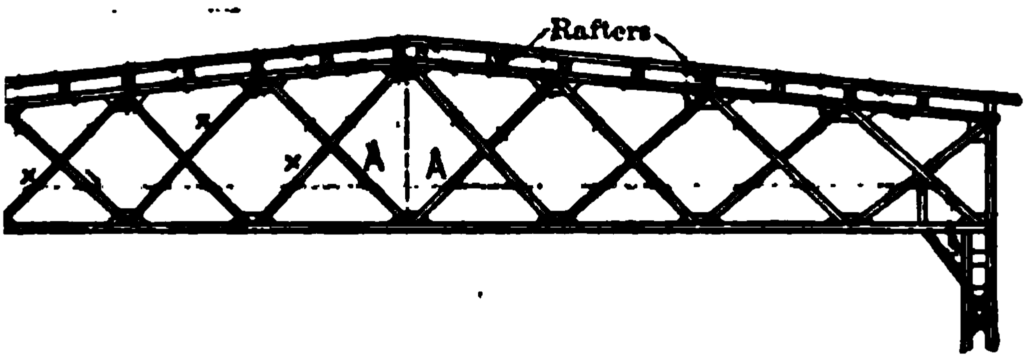

Fig. 58. Double Warren Truss

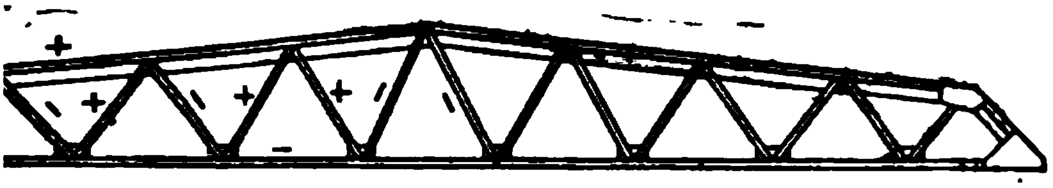
p chord. Fig. 60 shows a truss of 96-ft span over a pier-shed, y, the trusses being spaced 20 ft apart. They are about 10 ft 1 300 lb each. They were delivered from the shops completely riveted, and were raised and set in position by falls suspended s. The dimensions of these trusses are given in the Engineering ary 18, 1896.

Fig. 59. Pratt-truss Type. Span Fifty-seven Feet

d **Minus Signs** in these illustrations, as has been mentioned COMPRESSION and TENSION, respectively, under a uniformly dis- ad. The PLUS and MINUS SIGNS used together indicate that y be subject to EITHER TENSION OR COMPRESSION according of the wind or to the manner of distribution of the snow. In russes unsymmetrical loads may change the stresses in the



-truss Type. Pier-shed, New York City. Span Ninety-six Feet

e middle of the truss. This CHANGING OF STRESSES due to is considered on pages 1096 to 1104. The trusses shown in e almost invariably built with riveted connections and with hapes for all members.

ss, shown in Figs. 61 and 62, is the form of STEEL TRUSS support floor-loads, the members indicated by double lines ION and those indicated by single lines in TENSION. When

supporting floors are subject to moving loads, COUNTERTIES should be inserte where indicated by dotted lines. For trusses of this type PIN-CONNECTIONS a generally employed and are preferable to RIVETED CONNECTIONS.

The Quadrangular Truss. The truss shown in Fig. 63 is known as a QUA RANGULAR TRUSS, and has the proportions of the truss over the amphitheat

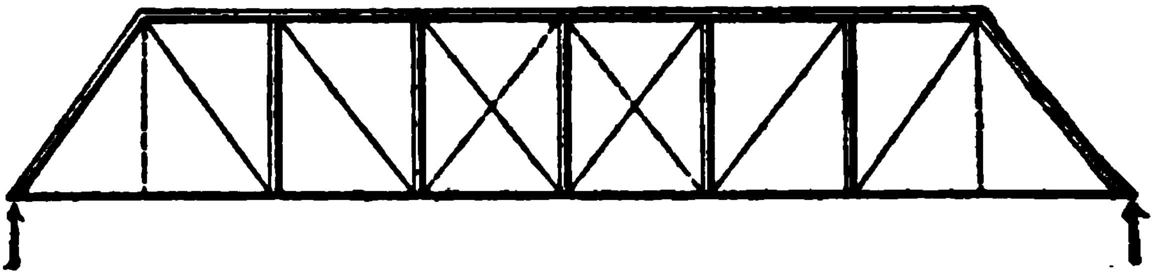


Fig. 61. Pratt Truss

of the Madison Square Garden, New York. Figs. 64 and 66, also, show variatio of this type, differing, however, from the latter in having all the diagonals each half-truss inclined in the same direction. In the typical truss their directi is usually reversed at about the middle of each half-span in order to keep the in tension. The PLUS AND MINUS SIGNS indicate the kind of stress produced

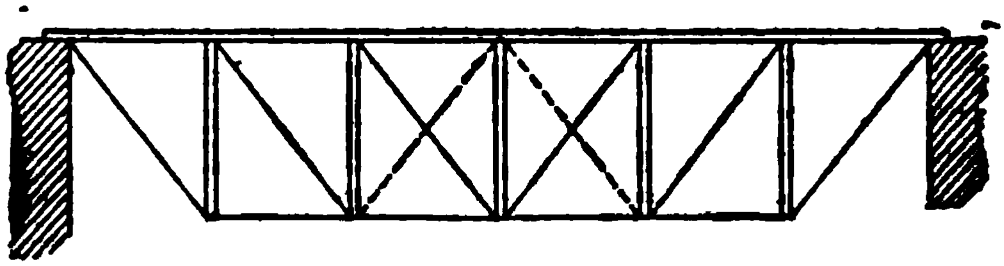

Fig. 62. Suspended Pratt Truss

a member by a uniformly distributed dead load. It should be noticed that t middle diagonals of trusses 64 and 66 are in compression. These trusses a well adapted to steel construction and to spans up to 180 ft. When the sp exceeds 100 ft one end of the truss should be supported on ROLLERS to allow f the EXPANSION or CONTRACTION in the steel. In these trusses the load is tra

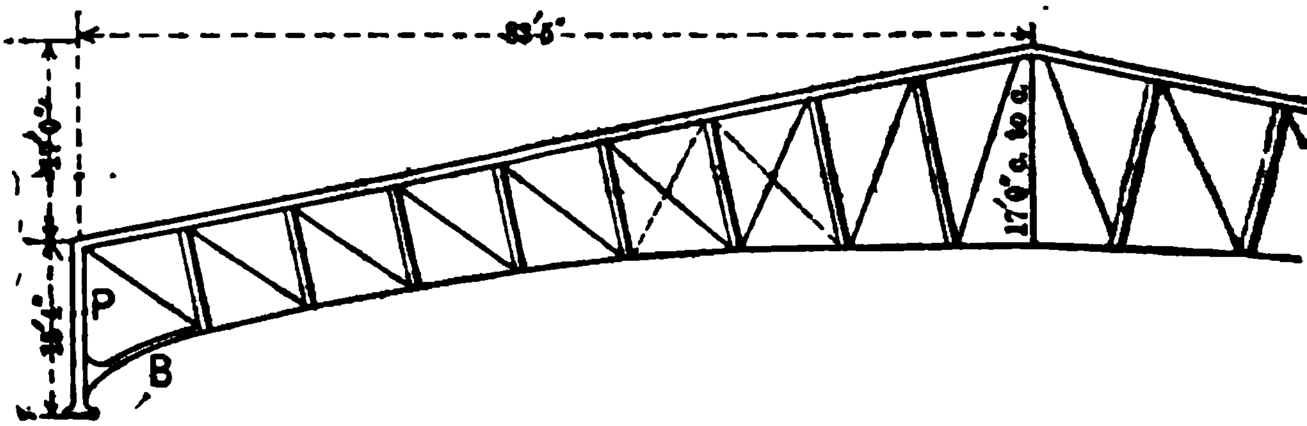

Fig. 63. Quadrangular Truss. Amphitheater, Madison Square Garden, New Yo City

mitted to the top of the column-support, the truss proper being included wit the points *A*, *B*, *C*, *D* and *E*, Figs. 64 and 65. The continuation of the bott chord to the columns is for the purpose of bracing the roof from the latter, th being no stresses in these end-chord members due to vertical loads. This me ber *B*, Fig. 63, and the corresponding member in Figs. 64 and 65 should be co structed to resist both tension and compression. For short spans the lo

uss with Broken Top Chord. A description is given in the ecord of October 15, 1904. The span is 78 ft between centers ng columns (Fig. 67).

)rill-Hall, New York City. A pin-connected truss, over the : 71st Regiment Armory, New York City, has a span of 190 ft escriptions of it are given in the Engineering News of June 16, : Engineering Record of July 2, 1904 (Fig. 68).

6. Arched Trusses

Between an Arched Truss and a Trussed Arch. For sup- f of very large spaces such as drill-halls, riding-halls, railway ., trusses in the form of arches or arches composed of trussed en employed. The essential difference between an ARCHED TRUSS RCH is that under vertical loads the supporting forces of an arched al, while for 1 they are

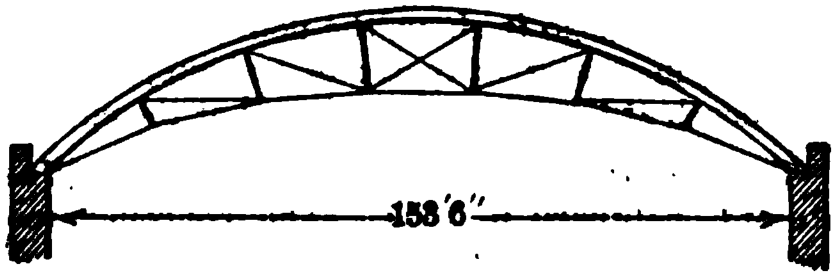

Fig. 69. Bowstring Truss

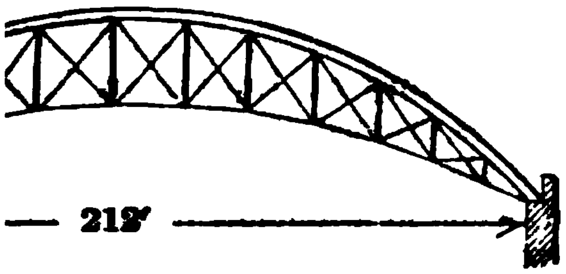
usses. Pre- r 1880 most iron trusses ere built in bow, from BOWSTRING russes of this type were built with spans of from 88 to 211 e at the middle of from 1/8 to 1/4 the span. At that time this type was considered the most economical for spans exceeding 120 ft, but in recent years they have been comparatively little used. Fig. 69 is the diagram of a bowstring truss with a span of 153 ft 6 in. The trusses in this particular case are spaced 21 ft 6 in apart.



70. Bowstring Truss

chord consists of a wrought-iron deck-beam 9 in deep, with plate, riveted to its upper flange. Towards the springing gthened with 7 by 5/8-in plates riveted on each side of the : struts are wrought-iron I beams 7 in deep. The bottom tional area of 6½ sq in and each diagonal tension-rod a

diameter of 1¼ in. Each truss is fixed at one end and rests on ROL at the other, allowing free expansion and contraction due to changes of t perature in the metal. Fig. 70 shows a similar truss having a span of 21 It consists of BOWSTRING PRINCIPALS spaced 24 ft apart. The rise is one- the span, the middle of the bottom chord rising 17 ft, and of the top chord 40 above the springing. The top chord is a 15-in wrought-iron I beam and bottom chord a round rod in short lengths, 4 in in diameter and thickene the joints. The ties of the bracing are of plate iron from 5 to 3 in in width, ⅝ in thick. The struts are formed of bars having the form of a cross. Du the last ten or twelve years a number of roofs have been supported on tru which can hardly be classed as SIMPLE TRUSSES; and yet it is questionabl they are TRUE ARCHES. Probably the frames act partially as simple tru and partially as arches.

Trusses for the Conservatory Building, Garfield Park, Chicago, I Engineering News, August 27, 1908. The roof is supported by POINTED TRUSS spaced 12 ft 6 in on centers. The truss-span is 80 ft 6 in, center to center end-supports. The chords of the trusses are parallel and connected by WARR BRACING. Both ends of the trusses are bolted to the supports and consequent there must be some horizontal thrust under certain conditions. The truss are riveted at all joints and have no HINGES or PINS.

Trusses for the Chicago and North Western Railway Station, Chicag Ill. Engineering Record, June 18, 1910. The roof over the main waiting-roo is carried by trusses each having a span of 90 ft 4 in and a rise of 31 ft and bei riveted to columns about 27 ft 6 in apart. All connections are riveted. T clear height of the bottom chords at the middle is 84 ft.

Trusses for the Peoria and Pekin Union Railway Trains-Shed, Peori Ill. Engineering Record, December 8, 1900. The trusses are riveted columns about 30 ft above the floor and spaced 20 ft apart. The truss-span 109 ft 4 in, center to center of end-supports, with a clear rise of about 10 The depth at the middle is 18 ft and at the end 6 ft. All connections are rivete

Trusses for the New Union Station, Washington, D. C. Engineeri Record, February 6, 1904. The concourse-roof is supported by CRESCE TRUSSES, each having a span of 132 ft 5½ in and a clear rise of 22 ft 5½ in. Th are spaced about 39 ft 4 in apart. One end of each truss rests upon maso and the other is riveted to a heavy plate girder. All connections are rivete The bottom chord at the middle is 45 ft above the floor. The trusses over t waiting-room of the same station have a span of 137 ft 8 in and a rise of 45 5 in. The chords are parallel and the ends are anchored with bolts to t masonry.

Trusses for the Riding-Hall, Armory for Squadron C, National Guar Brooklyn, N. Y. Engineering News, August 29, 1907. The main trusses ha a span of 179 ft 2 in and a rise of about 66 ft in the clear. The total depth the truss at the middle is 14 ft, while at the ends, where the chords appro each other and finally become vertical, it is 3 ft 3 in. One end is anchored the masonry and the other is on rollers. The trusses are in pairs 10 ft 11½ on centers and the pairs are spaced 38 ft 8½ in on centers. All connections riveted.

Trusses for the New Rock Island Terminal Station Train-Shed, Chica Ill. Engineering Record, September 12, 1903. Engineering News, August 1903. The trusses over the tracks have a span of 221 ft 1 in center to cent the end-pins, a rise of 28 ft and a depth at the middle of 25 ft 6 in. They

columns and are spaced from 10 ft 3 in to 19 ft 6 in apart. All
ections are made with pins.

es, or arches without hinges, are seldom employed in buildings. examples cited above the structures have the appearance of being ds, but a closer inspection indicates that they are not sufficiently arrant their being classed as FIXED ARCHES.

5. Cantilever Trusses

inciples. A CANTILEVER BEAM or CANTILEVER TRUSS is that ger beam or truss which extends beyond one of the supports, as 79 and *A* in Fig. 80. The overhanging portion *B* is called the M and the portion *C* the ANCHOR-SPAN. The cantilever-arm may nd another beam or truss. The term CANTILEVER was originally te a projecting beam which served as a bracket; in engineering note a beam or girder fixed at one end, by being either built into more commonly the case, extended a sufficient distance beyond rm an anchorage. Thus in Fig. 76, which shows a beam resting , *B* is the cantilever or cantilever-arm and *C* the anchor-span or s obvious that if this entire beam were uniformly loaded the l carry the greater part of the total load; and also, that an *V*, at the end of the cantilever, might cause a negative reaction t the support *D*, in which case the reaction at *P* would exceed beam, unless the negative reaction at *D* is considered as an Although both conditions of loading occur in practice, the the truss usually requires an anchorage rather than a support . As applied to roof-construction some such arrangement as 77 is generally required to make this method of support prac- wide middle span, with shorter spans or aisles on each side of ver-arm is usually made from ¼ to ⅓ the middle span and a RUSS, represented by *S*, supported by the arms of the canti- support the rest of the roof. In all such cases, therefore, can- st be used in pairs, one on each side of the building; and there passages outside of the principal span to permit the use of the

outer or anchor-spans. This arrangement is generally found in auditoriu armories, exhibition-halls and similar buildings, and is sometimes convenient adapted also to other classes of structures. Of course, in a large building a bea consisting of a single member such as is shown in Fig. 77 could not be use

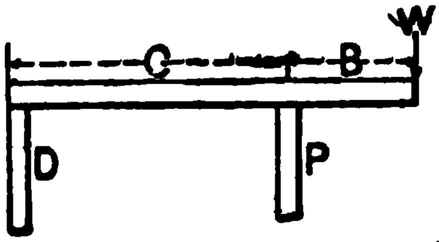

Fig. 76

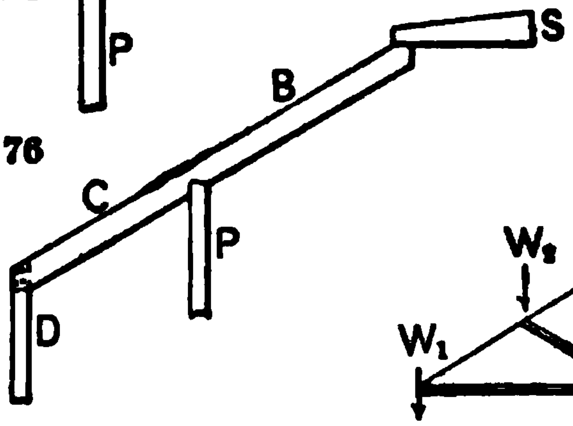

Fig. 77

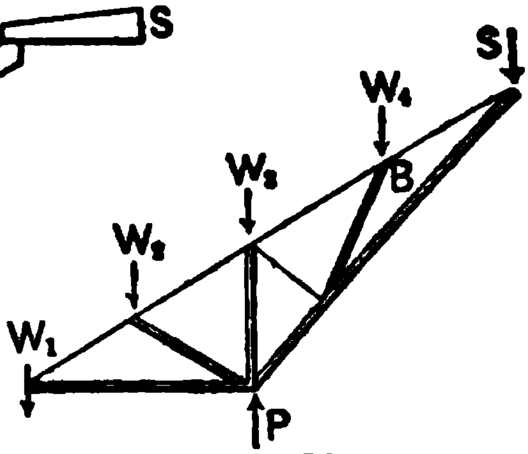

Fig. 78

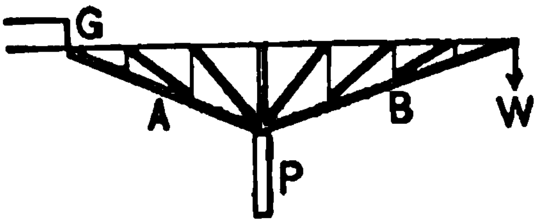

Fig. 79

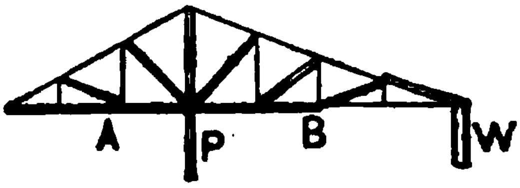

Fig. 80

Figs. 76 to 80. Cantilevers and Cantilever Trusses

but the principle of construction is the same whether the cantilever is a si member or a large truss. Fig. 78 is the diagram of a truss which takes the p of the beam *CB* in Fig. 77, the single lines representing the tension-memb and the double lines the compression-members. Fig. 81 shows the comp arrangement of two of these trusses with the accompanying middle truss, fo

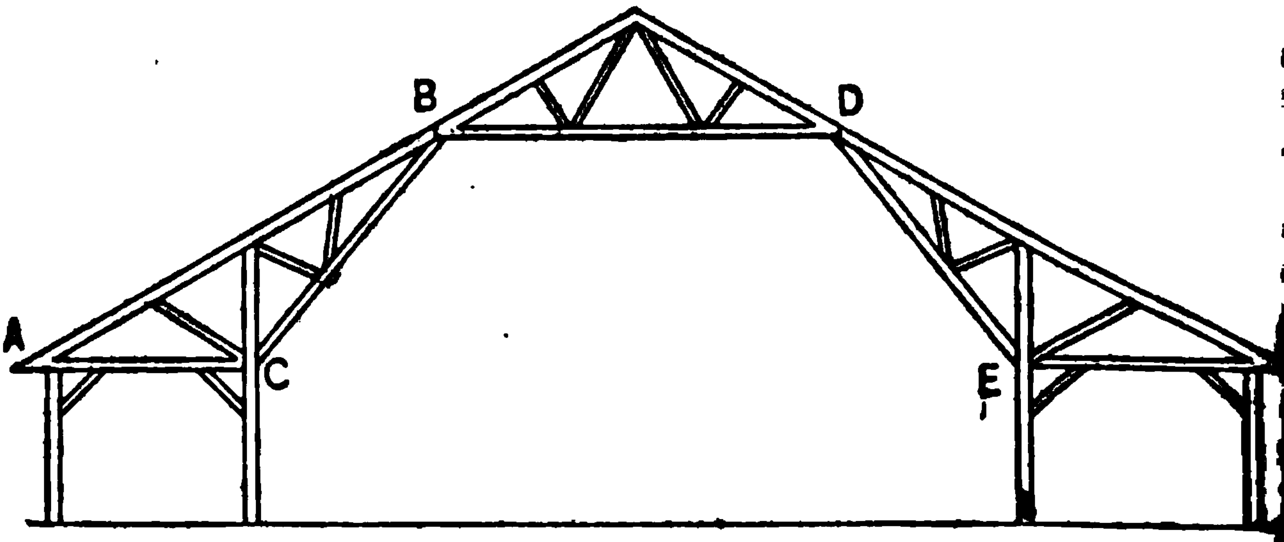

Fig. 81. Suggestion for Wooden Cantilever Truss

entire roof. The truss-principle shown in these figures may be develop almost any extent. The lower chord may be curved, but the general of the truss is best adapted to those roofs in which a wide middle part be supported by cantilevers. For bridge-trusses or floors the form sho Fig. 79 may be used; while for shed and platform-roofs, open on one side, t

own in Fig. 80 are about the only ones practicable. In this latter ortions of the arms are such that only a slight support is required onsequent compressive stress developed in the lower portion of the

s and Disadvantages of the Cantilever Truss. The cantilever some special advantages. The clear height in the middle is greater btained with any other type excepting the three-hinged arch; its light and graceful, and there is no horizontal thrust and consecessity for tie-rods. The particular advantage of this truss for very that it can be erected without scaffolding under the middle part, work this is considered as its only advantage. It is claimed by it engineers that the CANTILEVER TYPE OF TRUSS is not an economiot as desirable for spans of 150 ft or more as the THREE-HINGED s not as readily lend itself to methods of allowing for expansion n as the THREE-HINGED ARCH, the BOWSTRING TRUSS, or the QUADuss. For certain classes of buildings, however, and especially ldle span does not exceed 150 ft, it can perhaps be used with tural effect than is possible with other types, the cost remaining ie. For roofing platforms, grand-stands, etc., where an outer desired, it is the only type available.

rand-Stand, Monmouth Park, N. J. Fig. 82 is a diagram of TILEVER TRUSSES supporting the roof of the grand-stand at this

for Grand-Stand, Empire City Trotting Association, These trusses have CANTILEVER-ARMS at each end, 25 ft 6 in 5 ft 6 in on the other. The intermediate truss has a span of cture is described in the Engineering Record, February 10, mples of CANTILEVER ROOFS are given in Building Construction nce, Part III, by F. E. Kidder.

CHAPTER XXVII

STRESSES IN ROOF-TRUSSES

BY

MALVERD A. HOWE

PROFESSOR EMERITUS OF CIVIL ENGINEERING, ROSE POLYTECHNIC INSTITUTE

1. Roof-Loads. Data, Weights, Materials, Methods

Data for Roof-Trusses. Before the stresses in a roof-truss can be det mined it is necessary to decide upon the character of the roof-covering, t method of supporting it between the trusses, the geometrical shape and sp of the trusses and the spacing of the trusses.

Roofing Materials for Pitched Roofs. The materials suitable for coveri pitched roofs are slate, burnt-clay tiles, metal tiles or shingles, wooden shingl corrugated iron, tin with standing seams, standing-seam steel roofing a various kinds of ready roofing. The least slope to which these materials m be laid without danger of leaks, the weight per square foot of roof and the co parative cost are indicated in Table I. The cost, however, can only be conside as approximate, as it varies for different materials, localities and the scales wages.

Table I. Covering Materials for Pitched Roofs

Material	Least rise of rafter in 12 in	Comparativ cost per square
Slates, black	8	$7.00 to $12.(
Slates, green	8	7.00 to 10.(
Slates, red	8	12.00 to 17.(
Burnt-clay tiles, interlocking pattern	7	15.00 to 25.(
Tin shingles, painted	6	8.00 to 10.(
Galvanized-iron tile, painted	6	13.00 to 15.(
Cedar shingles, stained or painted	6	3.80 to 7.(
Corrugated iron, painted	3	4.00 to 4.(
Standing-seam steel roofing, painted	2	4.00 to 4.(
Ready roofing	1	3.50 to 4.(

Roofing Materials for Flat Roofs. Flat roofs or roofs having a fall from ½ to ¾ in to the foot are usually covered with tar and gravel, asph ready roofing, or tin with lock-and-solder joints. A good tin roof costs ab $8.00 a square, not including the painting. The other kinds vary from $ to $4.50 a square.

Manner of Supporting the Roof from the Trusses. Wooden roofs, s ported by wooden trusses, require common or jack-rafters to support the shea ing or slate, and generally purlins to support the rafters, although in some cas may be more economical to span the rafters from truss to truss (Fig. 17, Chap XXVI). When slates or burnt-clay tiles are used on steel roofs, they are usu secured to steel angles, running parallel with the walls and spaced from 8 10½ in apart, as may be necessary to accommodate the size of the slates

an is not more than 6 or 7 ft, the angles may be fastened to the As a rule, however, when slates or tiles are to be used, it is cheaper sses from 16 to 20 ft apart, and to use purlins and jack-rafters to aller angles. Quite often, wooden rafters and sheathing are trusses. This is more economical, but of course increases the otected steel is little if any better than wood. If corrugated d for roofing, the most economical construction for steel roofs is sses from 16 to 20 ft apart, and to use light I beams for purlins, ¼ ft on centers, as in Fig. 52, Chapter XXVI, the corrugated ed to the purlins by straps. If warm air comes in contact with a corrugated roof, either the roofing should be laid on boards, anticondensation lining should be provided, as otherwise the air will condense and fall on the floor or objects below. Flat quire rafters and sheathing, or fire-proof filling between the

usses. From the above it is seen that the economical spacing pends to a great extent upon the kind of roofing that is used, he span. As a general rule, however, the most economical as follows:

RUSSES under 80-ft span, from 12 to 16 ft on centers.
RUSSES over 80-ft span, from 16 to 24 ft on centers.
SSES under 80-ft span, from 16 to 20 ft on centers.
SSES over 80-ft span, from 20 to 40 ft on centers.

f a number of steel trusses of wide span is given in Chap- n the distance between the trusses exceeds 16 ft for wooden steel roofs, it is generally necessary to use trussed purlins. pon the kind of truss to be used, the spacing of the trusses and ion, a section-drawing of the roof should be made, showing e truss, the points at which the purlins are to be supported, porting the ceiling, if there is one, and any other loads that ed by the trusses. The section and truss-drawing, with the hts of roofing-materials, will furnish the necessary data for ds at each joint. Until the stresses have been determined, embers computed, and the joints detailed, an exact drawing t, of course, be made; but in order to compute the loads and ssary to know the positions of the joints, and these can be ficient accuracy before the exact sizes of the members are pter XXVI gives sufficient information regarding the various enable one to decide upon the height and the number and struts and ties; and the sizes of the members can be approx- minary drawings.

ng-Area Supported at Any Joint. Calculations for the re always based on the assumption that the loads are trans- , and that the members are free to move at the joints as if e actual joints may be made with riveted or other connec- t the joints are, of course, equal to the reactions of the pur- ams or principals, if these receive the ceiling-joists or rafters. he roof or ceiling is uniformly distributed, as is usually the ethod of computing the joint-loads is to determine the roof butory to the joint, and to multiply this area by the weight or . The area contributory to any joint is equal to the product sured half-way to the next joint, on each side, by the dis- -way to the next truss or wall. on each side. Thus if Fig. 1

represents truss 1, of Fig. 2, the roof-area contributory to joint 2 is, in square fe
$\frac{8+14}{2} \times a$. For truss 2, the area supported by the same joint is $\frac{14+12}{2} \times$
or, if we let D represent the length in feet of roof or ceiling supported at e
joint, the area in square feet supported by joint 2 is $a \times D$, and the area s

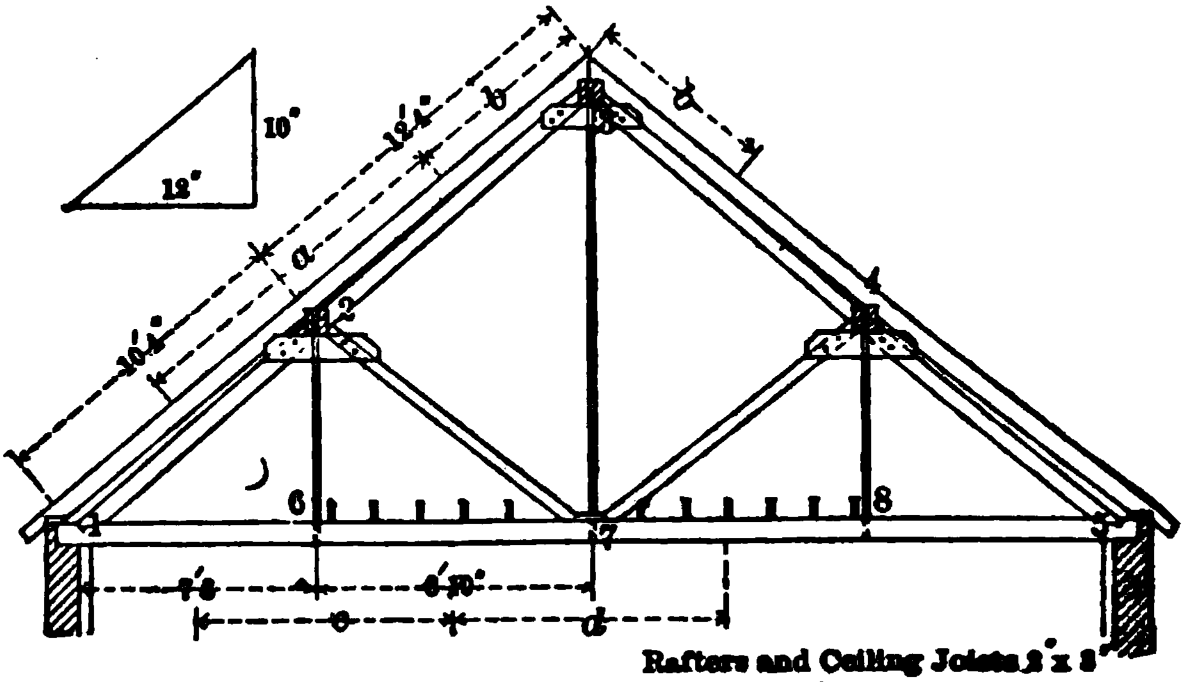

Fig. 1. King-rod Truss

ported by joint 3 is $2b \times D$. In the same way, the ceiling-area supporte
joint 6 is $c \times D$, the arrow-heads being half-way between the joints. It m
no material difference in the joint-loads whether the common rafters are
ported on purlins or whether they rest on the top chord of the truss, provi
the purlins come at or close to the jo
and the load is uniformly distribu
Thus the width of the ceiling cont
utory to joint 7 (Fig. 3) is equal t
just the same as in Fig. 1. The arra
ment in Fig. 1 produces cross-bea
stresses in the tie-beam, while tha
Fig. 3 does not. When the trusses
spaced a uniform distance apart, D,
2, is, of course, equal to the dist
between centers of trusses. When
trusses are not spaced uniformly,
equal to one-half the distance from
center of the truss on the left to
center of the truss on the right. Wh
purlin is more than 12 in from a joi
the roof-area is not symmetrical,
often the case at hips and valleys,
joint-load is determined by the pri
of the REACTION OF BEAMS, as explai

Wooden purlins weigh about 2 lb per sq ft of roof-surface when the span is betw
12 and 16 ft.

For steel roofs the sizes and weights of the purlins and rafters should be computed
each particular case.

Weight of Truss. To the weight of the roof-construction proper sho
be added an allowance for the weight of the truss. If trusses could be b
in exact accordance with the theoretical requirements their weight would
directly proportional to the roof-load and span; but as there is always s
extra material, it is impossible to determine the weight of the truss exactly u
it is completely designed. Several tables for the weights of wooden tru
and formulas for steel trusses have been published, but hardly any two of t
are alike. The following are some of the formulas in use:

For Wooden Trusses

$W = 0.04\,L + 0.000167\,L^2$	N. C. Ricker, for trusses like Fi and 5, Chapter XXVI.
$W = 0.50 + 0.075L$	H. S. Jacoby.

For Steel Trusses

$W = 0.75 + 0.075\,L$	Mansfield Merriman and Jacob
$W = 0.6 + 0.06\,L$, for heavy loads; $W = 0.4 + 0.04\,L$, for light loads	C. E. Fowler, for Fink trusses.
$W = \dfrac{P}{45}\left(1 + \dfrac{L}{5\sqrt{A}}\right)$	M. S. Ketchum, for steel mill-b ing trusses.
$W = 0.05\,L + 12/A$	H. G. Tyrrell.

In the above formulas, W = weight of truss in pounds per square foot of h
zontal projection of the roof supported, L = span in feet, A = distance betw
trusses, and P = capacity of truss in pounds per square foot of horizontal p
jection.

Tables IV and V, compiled from a comparison of other tables and form
and from the weights of actual trusses, are sufficiently accurate for the pu
of determining stresses. The weights given are probably slightly in exce
the actual weights of average trusses, as it is preferable to have the error, if
on the safe side. It should be noted that the weights are for each square
of roof-surface, and not for the horizontal area. Table VI gives the a
weights of a number of large steel roofs.

* For scissors trusses, increase one-third.
† Chapter XXVI.

The data for the first seven buildings in Table VI were compiled by H. (Tyrrell, who states that all of the seven roofs were proportioned for sla and plank roofing resting on wide rafters 2 ft apart, supported by steel purli about 10 ft apart. The spans given are measured from center to center of si bearings. Stresses were computed for a dead load of 25 lb per sq ft, a snow-lo of 10 lb per sq ft of sloping surface, and a horizontal wind-load of 40 lb per sq ft a 28-lb-per-sq-ft normal pressure. Data for computing the weights of floors a floor-loads supported by trusses, and for fire-proof construction, may be found Chapters XXI and XXIII.

Snow-Loads. As a basis for making an allowance for snow, Table VII perhaps as good a guide as any that can be given. When snow-guards a placed on a roof, the same allowance is made for a half-pitch as for a one-thi pitch.

Wind-Pressure.* For roofs having a pitch of 5 in or more to the foot, allowance must be made for wind-pressure. For trusses of the FINK, FAN, KI or QUEEN TYPES, the usual practice is to include the wind-pressure with t vertical loads, and to make a single allowance for both wind and snow, as duri a gale snow is not likely to stay on a steep roof. When the wind-pressure added to the vertical loads, the allowance for wind and snow combined sho not be less than indicated in Table VIII.

No roof-truss should be proportioned for a total load of less than 40 lb per sq of roof-surface except flat roofs in warm climates. For trusses having sp exceeding 100 ft (except trusses for flat roofs) and for trusses in which a part

* (See, also, Chapter XXX, page 1199, and pages 1394 and 1717.)

duce maximum stresses, or call for COUNTERBRACING, as is the case ERAL TRUSSES, and trusses with CURVED CHORDS, the stresses for all oadings should be found separately and each member of the truss for the maximum stress to which it may be subject under any ination of loads. For determining the stresses due to wind-pres- force of the wind is usually assumed to act in a direction normal, t-angles, to the slope of the roof. This force is commonly based on ind, producing a pressure of 30 lb against a vertical surface. This a wind-velocity of nearly 100 miles per hour. According to ıula,

$$P = 0.0032\ V^2$$

pressure in lb per sq ft against a surface normal to the direction ıd V = the velocity in miles per hour. For $P = 30$ lb, $V = 96.3$ ormal pressure per square foot of roof-surface corresponding to and 30 lb per sq ft against a vertical surface is given in Table IX.

. **Wind-Loads in Pounds per Square Foot of Roof-Surface***

Inclination of roof	Normal pressure P_n, pounds per square foot	
	$P = 30$ lb	$P = 20$ lb

ı Table IX are based on Duchemin's formula,

$$P_n = P \frac{2 \sin\theta}{1 + \sin^2\theta}$$

e pressure per square foot on a vertical surface, P_n the normal essure and θ the angle of inclination of the roof with the hori- ıd not only produces a pressure upon the windward side of the n upon the leeward side; therefore all roof-covering should be l, all joints in the trusses so constructed that they will resist pression, and the trusses themselves securely anchored to the

Loading for which Stresses should be Found. To deter- ım stresses under any possible condition of loading, stresses or the following cases:

due to permanent DEAD LOADS,
vering only one side of roof,
vering entire roof,
side of truss nearer the expansion-end,
side of truss nearer the fixed end.

lso, Chapter XXX, page 1199, and pages 1394 and 1717.)

It is generally assumed that the maximum wind-pressure and the snow-lo cannot act on the same half of the truss at the same time; hence the combi tions for maximum stress will be either cases 1 and 3 or cases 1, 2, and 4 or If the trusses are supported on iron columns instead of on walls the wind-fo is transferred to the foundations through the columns, producing a bendi moment in the columns. The stresses in the columns, trusses and knee-bra should therefore be determined for the wind-pressures against the side of t building and roof. These pressures are obtained by multiplying the area the vertical surfaces by the full pressure per square foot and the area of t roof by the normal component, given in Table IX.

Kansas City Auditorium. For the trusses supporting the roof of the Ka sas City Auditorium (Fig. 66, Chapter XXVI) stresses were computed for t following conditions: First, full dead and live load on both galleries and t roof-garden, and wind-pressure due to a velocity of 45 miles an hour; seco full dead load, snow-load, and gallery live load, wind-pressure 10 lb and load on roof-garden floor; third, full dead load and 50 lb wind-pressure; fourt full dead load and wind-pressure at 45 miles an hour, and full live loads gallery and roof-garden on one side only. Snow-loads throughout were tak at one-third of the dead load. Examples showing manner of combining t stresses due to different conditions of loading are given on pages 1114 and 1123

2. Examples of the Computation of Roof-Loads*

King-Rod Truss. Example 1. The first example considers the roof a truss shown in Fig. 1, page 1048, which it is assumed represents truss 2 of Fig. It is assumed that the timber is to be common white pine and that the roo to be covered with 3/16-in slate of medium size on 7/8-in sheathing. The ceil is to consist of lath and plaster. The dead load of roof and truss per squ foot of roof-surface is made up as follows:

	lb per sq
For slate	7¼
For sheathing	3
For rafters	3
For purlins	2
For truss	3
Total	18¼

For wind and snow-load combined there should be allowed about 28 lb (pitch being about 40°), which makes a total roof-load of 46¼ lb. To av fractions, however, the load is assumed to be 48 lb per sq ft. As the dista to truss 1, Fig. 2, is 14 ft and to truss 3, 12 ft, the length of roof supported the truss is 13 ft. The roof-area supported by the purlins at joint 2 is equa the distance *a* multiplied by 13 ft; and *a* is one-half the distance from the w plate to the ridge-purlin, or 22 ft 8 in divided by 2, or 11 ft 4 in, or 11⅓ Hence the roof-area supported at joint 2 is 11⅓ by 13 ft, or 147⅓ sq ft. roof-area supported by the purlins at joint 3 is 2 *b* by 13 ft, or 12⅓ by 13 ft 160⅓ sq ft. Multiplying the roof-areas by the load per square foot, 48 lb, t results 7 072 lb for the load at joint 2; and 7 696 lb for the load at joint 3. load at joint 4 is equal to that at 2, as the truss is symmetrical. The ceil loads at joints 6 and 7 are computed next. The ceiling-area supported at j 6 is $c \times 13$ ft, or 8¼ by 13 ft, or 107¼ sq ft. The area supported at joint 7 is by 13 ft, or 114⅝ sq ft. The actual weight of the ceiling per square foo

* In the following five examples all loads are considered as acting vertically.

ists and 10 lb for the lath and plaster; but where there is a large ible to be used for storage it is well to make a small allowance, sq ft, for any extra attic-load. Therefore, 18 lb per sq ft is he weight of the ceiling, which makes the weight at joints 6 and by 18 lb per sq ft, or 1 930 lb; and the weight at joint 7, 114⅚ sq r sq ft, or 2 067 lb. As soon as computed, the roof and ceiling-e marked on a truss-diagram, as in Fig. 10. The roof and ceiling-ı are transmitted directly to the wall and need not be taken into ermining the stresses in the truss.

182. Example 2. It is required to compute the joint-loads for n in Fig. 3, page 1049. All timber is to be of spruce and the roof d with shingles on 1-in sheathing. The ceiling is to be of lath The dead load is:

	lb per sq ft
shingles	2½
sheathing	3
rafters	2¼
purlins	2
truss	3
dead load per sq ft	12¾
for wind and snow	30
roof-load in pounds per square foot	42¾

of the ceiling it is well, for a truss of this kind, to allow at least It will be assumed that the trusses are to be spaced uniformly . Then the roof-area supported at joint 2 is 9⅚ by 15 ft, or the load at this joint is 6 306 lb. The purlin at joint 3 supports point midway to joint 2, to the ridge, or $b = 4$ ft 11 in + 8 ft 5 in, he roof-area supported at this joint is 13⅓ by 15 ft, or 200 sq is 8 550 lb. The loads at joints 4 and 5 are equal respectively 2. For the ceiling-loads at joints 7 and 8 there is an area to be to 12⅙ by 15 ft, or 182½ sq ft, which, multiplied by 20, gives

183. Example 3. For this example the church-roof shown in is considered. In this roof the trusses take the place of the g-beams, the sheathing spanning from truss to truss and the ıg being nailed to 1¼ by 2½-in furring strips, spaced 12 or 16 in ming that the parts of the trusses have the dimensions indi-e, and that the wood is white pine, the actual weight of one 00 lb. The roof-area supported by one truss is 170 sq ft, and of the trusses is about 7 lb per sq ft of roof-surface. This an twice that given in Table IV, owing principally to the close sses and also to the small dimensions of their members. The thing and shingles is about 5½ lb and 30 lb is allowed for wind-of is too steep for snow to lodge on it. This gives a total roof-r sq ft of sloping surface. For the weight of the ceiling 12 lb as no load other than its own weight is likely to come upon it. ported at joint 2 is 10⅚ by 2½ ft, or 27 sq ft. The area sup-and 5 is equal to 12⅓ by 2½ ft, or 31 sq ft for each. The ted at joint 3 is 14⅓ by 2½ ft, or 35½ sq ft. Multiplying the corresponding loads per square foot, there results 1 148 lb

for the load at joint 2, 1 318 lb for each load at joints 4 and 5, and 426 lb the load at joint 3.

Truss over Car-Barn. Example 4. In this example the roof is of co gated iron, supported by a steel truss of the shape shown in Fig. 55, Cha XXVI. This truss supports nothing but the corrugated iron, the purlins the pressure due to wind and snow, the use of the building not requiring suspending of any load from the trusses. In figuring the dead loads for s a roof, the sizes of the purlins and the gauge of the iron should first be defini

Fig. 4. Scissors Truss. (See, also, Fig. 24 and Chapter XXVIII, Fig. 2)

fixed, so that the weight per square foot of roof may be accurately determ In this instance the purlins are 5-in I beams spaced 4 ft 9 in on centers weighing 10 lb per linear foot. The weight of the purlins per square fo roof is therefore equal to 10 lb divided by 4¾, or 2.1 lb. For a span of 4 f the corrugated iron should be No. 18 gauge (see Corrugated Iron, Part III, 1601) weighing 2 lb per sq ft. For the weight of the truss and bracing the v taken is that given in Table V for a span of 100 ft and ¼-pitch, 10.8 lb.* gives a total dead load of 14.9 lb per sq ft of sloping surface.

For wind and snow we should allow 22 lb per sq ft if the building is sit in the Central states, making the total roof-load 36.9 lb per sq ft. It is generally recommended, however, that no roof should be designed for a less, all told, than 40 lb per sq ft; the joint-loads, therefore, should be com on that basis. The only loaded joints in this truss are those under the pu The trusses are spaced 19 ft 2¼ in and the purlins 4 ft 9 in on centers, th area supported at each upper joint being 91 sq ft. The joint-loads, the should be figured at 3 640 lb. Even for the locality in which it was buil

* The actual weight of this truss and bracing was 4 lb per sq ft of sloping which is remarkably small.

: roof; and it would hardly be considered safe for states further

s required for wind-pressure, but the snow-load is a large per- otal load in any of the Northern states, as indicated in Table VII.

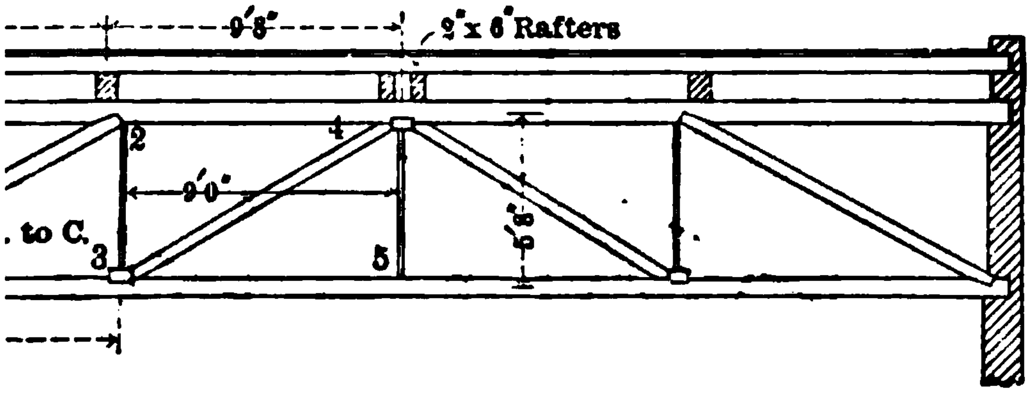

Fig. 5. Howe Truss

ie building is located in one of the Central states, 30 lb per sq ved for snow, making the total roof-load 47½ lb. The plaster eiling-joists weigh about 12¼ lb and as the roof-space is not for storage, 13 lb per sq ft is a sufficient allowance for the ceil- hat the trusses are to be uniformly spaced, 14 ft on centers, orted at joint 2 is 9½ by 14 ft, or 133 sq ft, and the area sup- 9⅝ by 14 ft, or 135½ sq ft. The ceiling-area supported at ft, or 130⅝ sq ft and at joint 5, 9 by 14 ft, or 126 sq ft. Mul- iese areas by the corresponding load per square foot, we have d at joint 2, 6 428 lb at joint 4, 1 699 lb at joint 3, and 1 638 lb actice it is hardly worth while to compute the stresses closer it the loads may as well be put down at an even 50 or 100 lb obtained by computation. When the roof is supported by often some joints of the truss which have no load. Thus for Fig. 16, Chapter XXVI, there are no loads on joints 2, 6 and supported at joint 4 (Fig. 16) is equal to one-half the distance the distance halfway to the truss on each side. If the lower ing-joists, there is a load at each of the joints 3, 5, 7, 9, etc. can be drawn for any arrangement of loads, the important oute the loads exactly as they are placed on the truss.
oles illustrate fairly well the method of computing the loads of trusses. Other special cases of loading should be com- principles.

3. Determination of Stresses by Computation

Stresses. To determine the stresses, a DIAGRAM OF THE TRUSS, compos of single lines representing the central axial or median lines of the truss-membe should first be carefully drawn to a scale and the loads at the different joi indicated by arrows and numbers as in Figs. 10 and 12. If the center lines the members, as they are actually placed, do not intersect at common poin they must be made to do so in the diagram, as the stresses can be COMPUTED o on the assumption that the center lines of all members meeting at any jo intersect at a common point. In wooden trusses it is not always practicable place the members so that their center lines meet in a common point at ea joint; but this condition should obtain as nearly as practicable, and in st trusses the joint-connections should be made so that the lines passing throu the centers of gravity of the cross-sections of the members meeting at a joi intersect in the same point.

on of **Stresses.** As a general rule, the stresses in a roof-truss can much more readily by the GRAPHIC METHOD than by MATHEMATI-IONS and with as close a degree of accuracy as is necessary. There is of trusses, however, for which the stresses can be more easily COMPUTATION. Such trusses must be symmetrical in shape ads all alike, as is quite frequently the case with simple steel roofs ng-load.

) XIII give constants by which the stresses in Fink and fan readily COMPUTED simply by multiplying the constant by the load. These tables apply, however, only when the rafter is struts into equal spaces, giving equal panel-loads. For any is the stresses should be determined by the GRAPHIC METHOD.

Table XIV gives coefficients which are general for any span and depth eight-panel roof-trusses with the Howe and Pratt types of bracing. Tables and XVI give formulas for COMPUTING the stresses in symmetrical Howe Pratt trusses which are symmetrically loaded. The coefficients are given trusses having an odd number of panels. For the Howe truss with an e number of panels the coefficients for the center load on the top chord are divided by two. For the center load on the bottom chord the coefficients also divided by two, except that for the center vertical, which remains un

truss with an even number of panels the coefficients are divided : center loads for all pieces, except that for the center vertical : top chord, the coefficient remains unity. For the young architect se tables will be found useful in furnishing a check upon stresses GRAPHIC METHODS.

For loads p_1, p_2, etc., the coefficients for the chords and diagonals are the same given for the loads P_1, P_2, etc. The coefficients for the verticals for loads p_1, p_2, etc. are given in the supplementary table below the general table. Tension is indicat in the truss-diagram by light lines.

ımples Showing Use of Tables in Stress-Computations

an Truss. Example 1. In this example a simple fan truss of ; considered. The distance on centers of trusses is 12 ft. The ss is 9 ft, or $l/h = 4$. The total load per square foot of roof is 40 lb. of rafter is 20 ft, nearly. The panel-load, $P = {}^{20}/_{3} \times 12 \times 40 =$ ıen from Table X,

›wer end of rafter $A = 3\ 200 \times 5.59 = 17\ 888$ lb
ıds of main tie $F = 3\ 200 \times 5.00 = 16\ 000$ lb
:nter of main tie $G = 3\ 200 \times 3.00 = 9\ 600$ lb
races D and $E = 3\ 200 \times 1.08 = 3\ 456$ lb
e $K = 3\ 200 \times 2 = 6\ 400$ lb

ıl Howe Truss. Example 2. (Table XV.) A five-panel Howe lered, for which $h = 6$ ft, $a = 9$ ft, $b = 10$ ft and $c = 12$ ft. Let the ced 10 ft on centers, the roof-load be 40 lb per sq ft and the ceiling- : sq ft. The panel-loads become:

$$\left.\begin{array}{l} 9+10)\ (10 \times 40) = 3\ 800 \text{ lb} \\ 9+10)\ (10 \times 15) = 1\ 400 \text{ lb} \end{array}\right\} = 5\ 200 \text{ lb}$$

$$\left.\begin{array}{l} 0+12)\ (10 \times 40) = 4\ 400 \text{ lb} \\ 0+12)\ (10 \times 15) = 1\ 700 \text{ lb} \end{array}\right\} = 6\ 100 \text{ lb}$$

ı $= {}^{9}/_{6} \times 5\ 200 + {}^{9}/_{6} \times 6\ 100 = 17\ 000$ lb
ı $= {}^{9}/_{6} \times 5\ 200 + {}^{19}/_{6} \times 6\ 100 = 27\ 100$ lb

nation of Stresses in Roof-Trusses by Graphic Methods

.c **Method** is the simplest and in most cases the quickest method · the stresses in a roof-truss; and it has, besides, the additional being applicable to any true truss-form or any arrangement of is also less chance of making a mistake in the GRAPHIC METHOD :thod of NUMERICAL COMPUTATION, as an error in the graphical t always becomes manifest. When the principles are under- ›IAGRAMS can be very quickly drawn, without the aid of books the forms of trusses in common use, the method of drawing the is quite simple; and a careful study of the following examples, ›y a little practice in drawing the diagrams, should enable any ;htsman, or builder to understand the principles involved in the .LYSIS OF ROOF-TRUSSES.

Ipon Which the Graphic Method is Based. To thoroughly ; method, a knowledge of the COMPOSITION AND RESOLUTION OF ›lained in Chapter VI, is essential; and before studying this dent should read carefully pages 288 and 289. The theorems ›lained on these pages form the basis of GRAPHIC STATICS. IC METHOD all forces, including the loads, are represented :s, and the directions of the forces must be constantly kept in is of assistance to indicate the direction of a force by an arrow- ıed on page 289. The direction in which a force acts with refer- indicates, also, whether it is a PUSHING or a PULLING force, or nber on which the force or in which the stress acts is in COMPRES- r. This is more fully explained in the following pages, and also ith several of the stress-diagrams.

Forces and Stresses which Act On and In a Truss. Every stress-di gram represents three sets of forces, viz., the external LOADS, the supporti forces or REACTIONS, and the STRESSES in the truss-members.

Supporting Forces or Reactions. For a truss to remain in place, two the conditions for equilibrium are that the algebraic sums of the vertical a horizontal components of all the forces acting upon the truss must respective equal zero. Then the horizontal and vertical components of the supporti forces or reactions, taken together, must respectively equal the horizontal a vertical components of the loads. The LOADS and REACTIONS are consider as the EXTERNAL FORCES acting on the truss and form part of the STRESS-DIAGRA

Symmetrical Loads. When the loads or vertical forces are symmetrical each side of the middle of the span, the supporting forces are equal, and each equal to one-half the total load on the truss.

Unsymmetrical Loads. When the loads are not symmetrical about t middle, either in regard to point of application or to magnitude, the supporti forces are unequal and in most cases must be determined before the stress-di gram can be drawn. The supporting forces for unsymmetrically loaded trus may be computed by the method of the MOMENTS OF FORCES, explained pages 322 to 324.

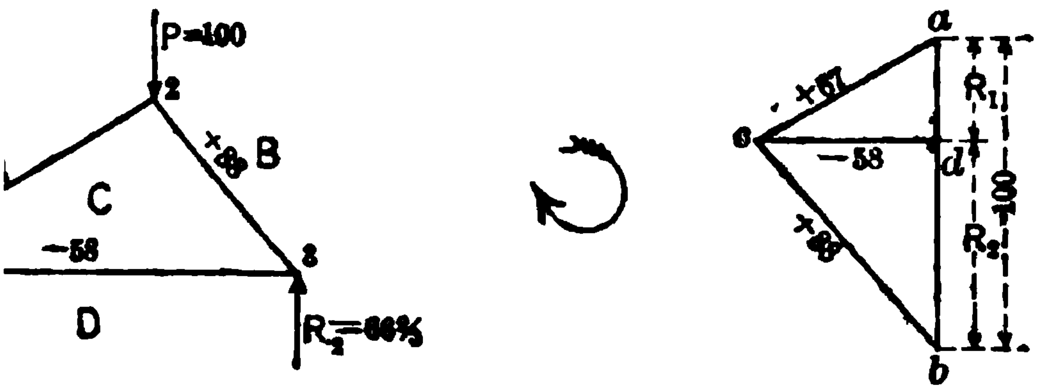
Stress-Diagrams for Vertical Loads. Before the stress-diagram for a tr can be drawn, it is necessary to make a skeleton drawing of the truss, representi the central or median lines of the members as explained on page 1058. T diagram, called the TRUSS-DIAGRAM, should be drawn on the same sheet paper as the STRESS-DIAGRAM, for convenience in drawing the latter. T truss-diagram should also have all of the loads which come on the truss indicat by arrows and figures, as in the following examples.

Supporting Forces. The SUPPORTING FORCES, also, should be indicated the TRUSS-DIAGRAM as in Fig. 10. These forces are determined as explain on pages 322 to 324.

Lettering the Truss-Diagram. After the truss-diagram is drawn, it is co venient to letter it according to the method known as Bow's NOTATION, whi allows a ready comparison of the TRUSS-DIAGRAM and the STRESS-DIAGRA and also enables the student to readily draw the stress-diagram and to imme ately determine the CHARACTER as well as the MAGNITUDE of the stresses. T essential principle of this method is the LETTERING of each space on each s of every external force and of every member of the truss, so that on the tru diagram a truss-member or external force is denoted by the letters on ea side of it. When the stress-diagram is drawn, it will be found that the sa letters come at the ends of the lines representing the external forces and t stresses in the truss-members.

The Simple Triangular Frame is much used in building construction, a most forms of roof-trusses are combinations of such triangles. It is, therefo worth while to show how easily the above principles may be used to determi the stresses in such a frame. Diagram 1, Fig. 6, represents the TRUSS-DIAGR of a triangular frame properly lettered. A load of 100 lb is applied at the ap The weight of the frame is disregarded. In diagram 2, a vertical line *ab* is draw 1 in long (say to a scale of 100 lb to the inch), representing the force A From *b*, *bd* is drawn equal to R_2 and from *d*, *da* equal to R_1. These three li represent the external forces acting on the truss, and the polygon *abda*, cal the FORCE-POLYGON, is always a CLOSED FIGURE if the forces are in EQUILIBRIU Since the force *AB* is vertical and R_1 and R_2 are parallel to *AB*, the figure be a straight line, *bd* and *da* coinciding with *ab*. If the external forces form a CLOS

:n laid off to scale, usually in order, the frame or truss upon which
not be moved either vertically or horizontally by the forces. The
ON should always be drawn and closed before any attempt is made
the stresses in the members of the truss. The stresses in the
he truss will now be found, beginning with those meeting at joint 1.
d *CD* meet at this joint. The stresses in these two pieces and R_1 are
RM and, consequently, if laid off in order will form a CLOSED FIGURE
Chapter VI. In diagram 2, *da* represents R_1 in MAGNITUDE and
From *a* draw a line parallel to *AC* and from *d* a line parallel to *CD*



l. Truss-diagram 2. Stress-diagram

Fig. 6. Triangular Frame

iem until they intersect at *c*. *ac* is the stress in *AC*, and *cd* that
and *da*, or R_1, are in EQUILIBRIUM since they form a CLOSED FIG-
the forces in order, *da*, or R_1, is known to act towards the joint.
ac is also towards the joint and hence the stress is of the same
ie force R_1 and the piece *AC* is in COMPRESSION. *AC* pushes
it as R_1 does. Continuing around the stress-polygon *dac*, in the
cd acts away from the joint and the stress in *CD* is opposite in
ie force R_1, or *CD* is in TENSION. *CD* pulls away from joint 1.
stresses in the pieces *BC* and *CA* and the force *AB* are in EQUI-
sides of the STRESS-POLYGON are *ab*, *bc* and *ca* (diagram 2). The
represents the load of 100 lb acts down and towards the joint,
ict towards this joint, showing that the stresses in *BC* and *CA*
character as the force *AB*, or that the pieces push against the
each is in COMPRESSION. At joint 3, the two pieces meeting are
The STRESS-POLYGON is *bdc*. Here *bd* acts towards the joint, *dc*
joint, and *cb* towards the joint. As found before, the stress in
and that in *CB*, COMPRESSION. Diagram 2 is made up of three
rs, one for each of the joints shown in diagram 1. Each of these
sidered independently when determining the MAGNITUDE and
he stresses or forces. This is important to remember when the
s are combined as in diagram 2. In determining the CHARACTER
4*C*, for example, from the STRESS-POLYGON *dac* for joint 1, the
vards joint 1, while from the STRESS-POLYGON *abc* for joint 2, *ca*
at 2. In both cases the piece *AC* is pushing against the joints
s in COMPRESSION. If arrow-heads are used in indicating the di-
orces in the STRESS-POLYGONS, they should be erased as soon as
f the stresses for the joint being considered have been found;
polygons are combined as in diagram 2, each line will have two
iting in opposite directions, leading to confusion. Arrow-heads
on the TRUSS-DIAGRAM. Each piece will have two arrow-heads,
referring to the joint at the end. When the arrow-heads point

away from each other the piece is in COMPRESSION, and when they po towards each other the piece is in tension.

It is important to keep in mind the direction in which the forces and stres are considered in order, in going around the truss or around a joint. In Fi 6 and 8 the curved arrows show that a clockwise direction has been chos This makes the stress-lines of the stress-diagram come on the left of the lo line. This direction has been taken for all the trusses in this chapter, exc for a few diagrams for wind-loads. The stres could have been determined just as well taking a contra-clockwise direction.

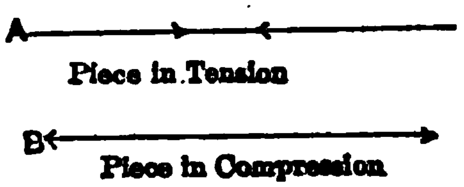


Fig. 7. Indication of Character of Stress

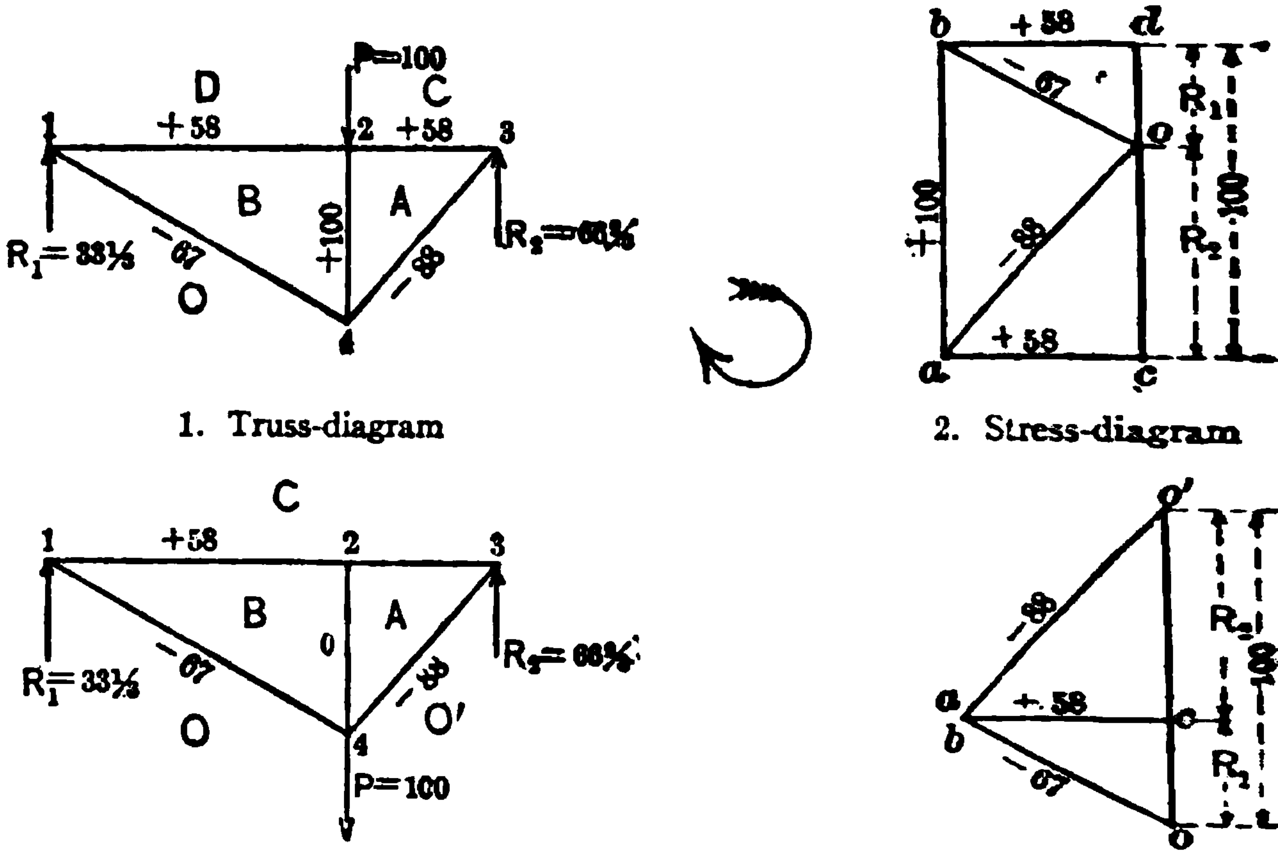
If two men pull on the two ends of a ro exerting PULLING FORCES of equal intensity, TENSIONAL STRESS in every cross-section of rope is equal to the FORCE with which one m pulls; and each end of the rope pulls away fr the man holding it, with a FORCE equal in magnitude to that which he exe Thus if each man exerts a FORCE of 100 lb the STRESS in the rope is 100 lb each end of the rope pulls away with a FORCE of 100 lb. If the men push agai the two ends of a piece of timber with a FORCE of 100 lb, the timber pus against each man with a FORCE of 100 lb, although the entire COMPRESS STRESS in every cross-section of the timber is but 100 lb. Consequen STRESS-LINES are sometimes drawn with arrow-heads pointing towards e other, as at A, Fig. 7, denoting TENSION; or with arrow-heads point



1. Truss-diagram 2. Stress-diagram

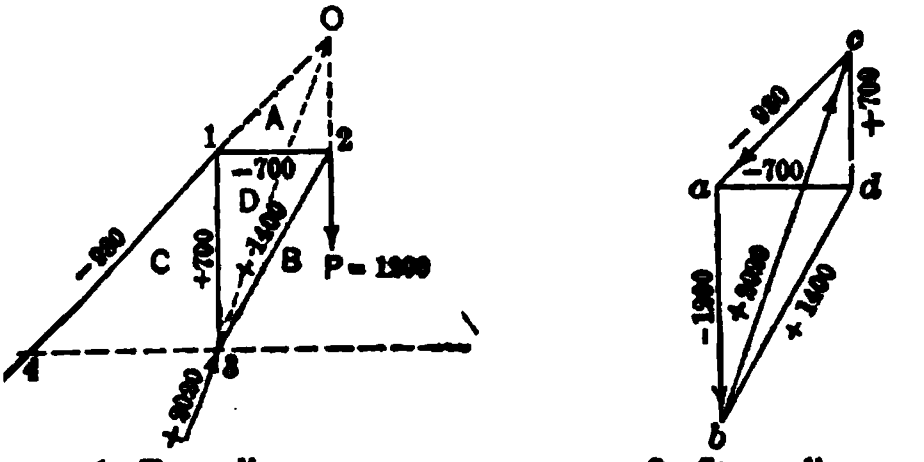
3. Truss-diagram 4. Stress-diagram

Fig. 8. Trussed Beam

in opposite directions, as at B, denoting COMPRESSION. It is better, howe to omit arrow-heads on STRESS-LINES, putting them on lines represen EXTERNAL FORCES only. The STRESS in any member of a truss act opposite directions at the two ends of the piece. This is an important t to remember in drawing STRESS-DIAGRAMS.

The Trussed Beam. Fig. 8 shows a load supported by a beam, post or s and two ties instead of by two struts and a tie. The effect on the rod form

s the same whether the load is applied as shown in diagram 1, or iagram 3. Considering the case shown in diagram 1: The FORCE-*od* (diagram 2); the sides of the STRESS-POLYGON for joint 1 are *od*, e stress in *DB* being compression, and that in *BO*, tension. For les of the stress-polygon are *dc*, *ca*, *ab* and *bd*, the stress in *CA* be-on; that in *AB*, compression; and that in *BD*, compression. For es of the stress-polygon are *ac*, *co* and *oa*. The stress in *AC* is com- that in *OA*, tension. The condition shown in diagram 3, where



1. Truss-diagram 2. Stress-diagram

Fig. 9. Crane Truss

ended from joint 4, leads to a different form of STRESS-DIAGRAM, d of construction remains the same. The stresses in the pieces ith the exception that the stress in the piece *AB* is zero for the case am 3.

Truss. Fig. 9, diagram 1, shows the TRUSS-DIAGRAM of a CRANE ical load at joint 2. The EXTERNAL FORCES acting on the frame t joint 2, the supporting force at joint 3, and the stress in the the frame is in equilibrium under the action of these three forces, a point.

n. The sides of this polygon are *bc*, *ca* and *ab*. *ca* is the stress hich is in tension. The stress-polygons for each joint can now n and the stresses in the members of the frame determined

EXAMPLES, worked out in detail and with considerable repeti- the student to grasp the principles of the GRAPHIC METHOD TRESSES IN FRAMED STRUCTURES.

uss. Example 1. Fig. 10 shows the TRUSS-DIAGRAM of the in Fig. 1, properly drawn, lettered and figured, ready for

drawing the STRESS-DIAGRAM. The supporting force at the left is SM, the lo at joint 1 is MA, the bottom of the rafter is AE, the left portion of the tie-bea or bottom chord is ES, etc. The loads acting at joints 1, 2, 3, 4 and 5 a designated as MA, AB, BC, CD and DN respectively, and those at joints 8, and 6 as OP, PQ and QS respectively. It makes no difference what lette are used, except that it is better to first letter the outside spaces consecutive and then the inside spaces.

Force-Polygon. The FORCE-POLYGON is now constructed by laying off scale (Fig. 10A) the external forces in order, beginning with the force MA, a following with AB, BC, CD, DN laid downward, NO laid off upward, OP, P QS laid off downward, and SM laid upward. If the work is correct, the forces form a CLOSED FIGURE.

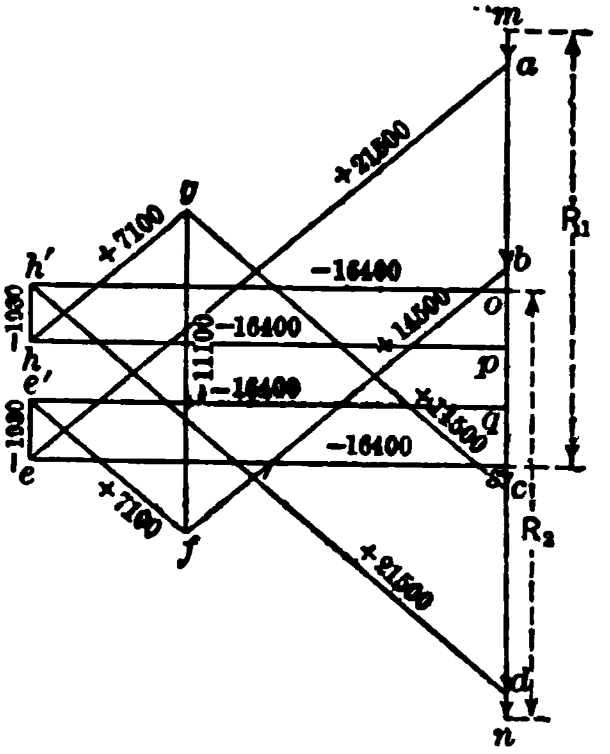

Fig. 10A. King-rod Truss. Stress-diagram

Stress-Diagrams. The STRESS-DI GRAM is drawn by taking the forces acti on the joints in consecutive order, co mencing at one of the supports. It convenient to start with the support the left, or at joint 1. In actual co putations it is not necessary to numb the joints, but in order to refer to the in the description it is necessary to nu ber them in the illustrations. Commen ing at joint 1, the first step in drawi the STRESS-DIAGRAM is to draw a vertic line to a scale of POUNDS-TO-THE-INCH represent the supporting force SM. Th line is the line sm already drawn in co structing the FORCE-POLYGON (Fig. 10 which might be drawn to the scale of 16 000 lb to the inch. It is best use a scale as large as convenient in order to have a relatively small STRES DIAGRAM. An engineer's scale, one divided to 10ths, 20ths, 30ths, etc., of inch, is found most convenient for these drawings. The small letter s is plac at the bottom of the line sm, and the letter m at the top. From m is laid off representing the load MA. A line is then drawn from a, parallel to the raft AE, and a line from s parallel to the tie-beam ES. The two lines meet at and ae represents the stress in AE and es the stress in ES. The supporting for represented by sm, acts upward, and the others follow in rotation, showing th ae acts towards joint 1 and that the member AE is in COMPRESSION, and sho ing that es acts from joint 1 and that the member ES is in TENSION. Consid next the stresses at joint 6. Commencing at the bottom of the joint and goi around to the left, the first force that is known is the load QS, or 1 930 lb, whi is measured to the scale used from q to s, downward, as the loads act downwa The point s was located in drawing the STRESS-POLYGON for joint 1, and q an in constructing the FORCE-POLYGON for the external forces. The next st that is known is the stress se which has just been determined. As this st acts to the right from joint 1, it will act to the left from joint 6, as the stre in the two ends of a strut or a tie act in opposite directions, as explained on p 1068. The stresses in EE' and $E'Q$ are not known, so from e a line is dra parallel to EE' and extended so that a line drawn from its extremity e' parallel to $E'Q$ closes on q. The lines ee' and $e'q$ are thus found, which rep sent the stresses in EE' and $E'Q$ respectively. Starting with se, the stres

be TENSION and acting from joint 6, and going around the diagram E' and E'Q are found to be in TENSION. At joint 2 the stresses A and the force or load AB are known, leaving the stresses in BF e determined. From a lay off downward ab equal to the force or rom b draw a line parallel to BF, and from e' a line parallel to g these lines until they intersect at f; then bf is the stress in BF n FE'. Both members are in COMPRESSION. At joint 3, the un- or stresses are the stresses in CG and GF. From c draw a line , and from f a line parallel to GF. The two lines intersect at g, stress in at in GF. MPRESSION TENSION. uss is sym- symmetri- the stresses rs on the middle are n those on stresses in m the left have been that it is

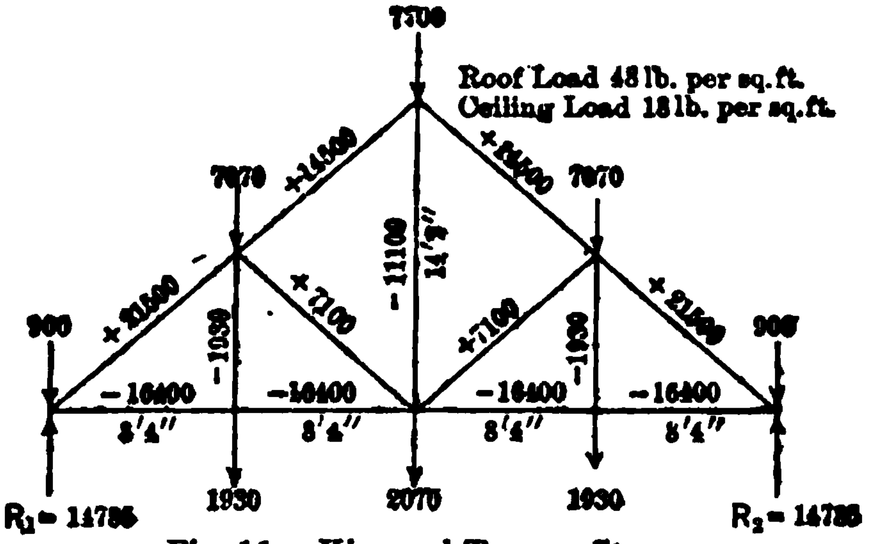

Fig. 11. King-rod Truss. Stresses

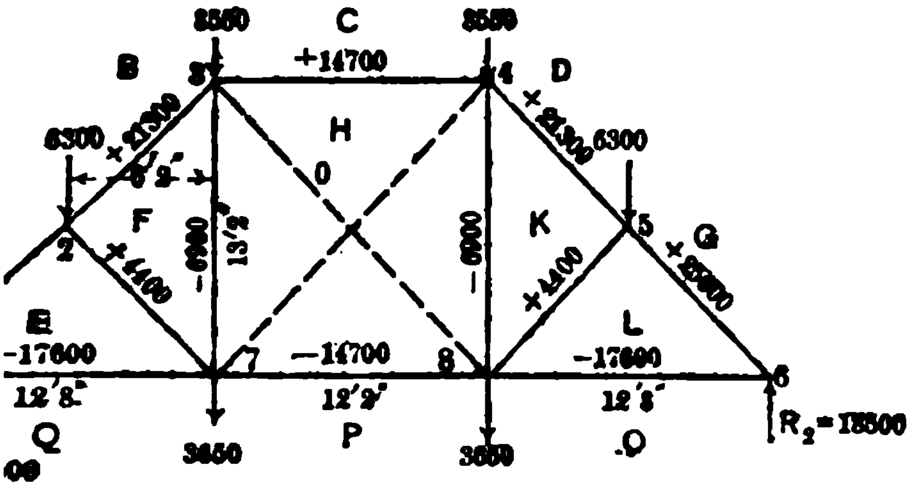
to draw the STRESS-POLYGONS for joints 4, 5, 8 and 7. It e to complete the STRESS-DIAGRAM including the stresses for the truss. A closed symmetrical figure will result, unless some n the construction, thus checking the work. The scale is now different lines of the STRESS-DIAGRAM and the MAGNITUDES OF btained as indicated on the corresponding lines of the TRUSS-DIA-

In practice the diagrams of Figs. 10 and 11 are combined in



russ. Truss-diagram. (See, also, Figs. 3, 53 and 54 and Chapter XXVIII, Fig. 1)

hey are shown separately here merely to indicate the succes- lrawing of the diagrams and in the determination of the stresses.

Truss. Example 2. The diagram in Fig. 12 represents the he members of the QUEEN TRUSS shown in Fig. 3; and the re those found in example 2, page 1055. The middle braces in are indicated by dotted lines in the truss-diagram, because ical load there are no stresses in these members, and they are resented by lines in the stress-diagram. As the truss is syr

metrically loaded, each supporting force or reaction is equal to one-half the tot load, or 18 500 lb. There are no purlins at joints 1 and 6 to carry rafters an ceiling-joists, which are supported by the walls of the building, so there are n external loads at these joints as in the previous example. The very small de load due to the truss itself is neglected. To draw the force-polygon, first dra the vertical line *qa* (Fig. 12A) equal in length, to some scale, to the magnitu of the left supporting force; then in rotation and at the same scale lay off tl distances *ab*, *bc*, *cd* and *dg*, downward; *go*, equal to the right supporting forc upward; and *op* and *pq* downward, closing the figure at *q*. To construct tl combined stress-diagram using the force-polygon just drawn, as a foundatio first consider joint 1. From *a* draw a line parallel to *AE* and from *q* a li parallel to *EQ*. The triangle *qae* represents tl three forces in equilibrium, meeting in a point an acting at joint 1. As the supporting forces a upward, the arrow-head on *qa* points upward. Fo lowing the sides of the stress-polygon *qae* in rotatio *ae* acts towards the joint and *eq* from the join showing that *ae* is in compression and *eq* in tensio Next determine the stresses acting at joint 2. Tl stress in *EA* is now known and represented by tl line *ea*, and as the stress at joint 2 acts in a directi opposite to that at joint 1, it now acts upwa towards joint 2. The next force is the load, 6 3 lb, which acts downward. The point *b* has alread been found by measuring from *a* a distance equal 6 300 lb at the same scale as used in drawing *q* There now remain two stresses to be found for joi 2, those in *BF* and *FE*. Draw *bf* parallel to *BF*, an *fe* parallel to *FE*, the two lines intersecting at .

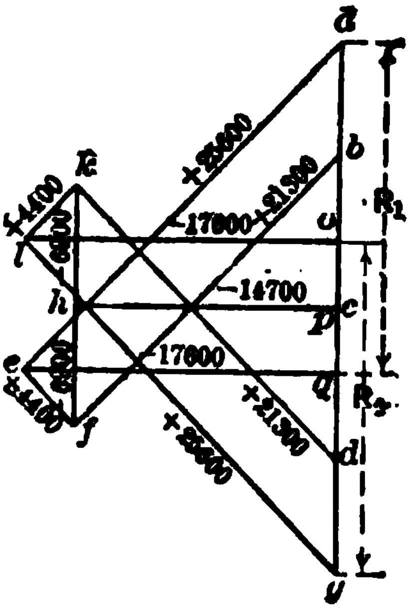


Fig. 12A. Queen Truss. Stress-diagram

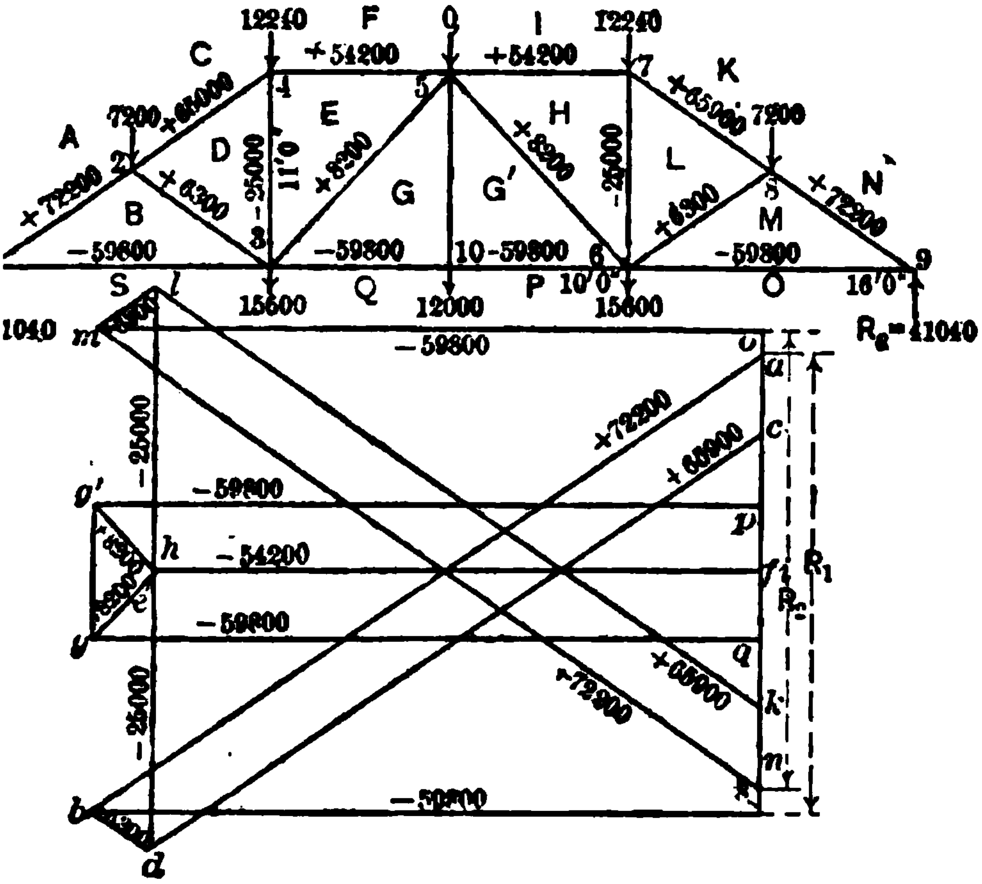
Then the sides of the polygon *abfe* represent respectively the magnitud of the four forces acting at joint 2; and the character of the stresses determined by the directions in which the stress-lines are drawn, in orde in going around the joint. In this case they all act toward the join and *EA*, *BF* and *FE* are in compression. The stresses acting at joint 3 or may be determined next, as only two of them are unknown at either join Considering the external force and the three stresses acting at joint 3, the stre in *FB* has been determined and is represented by the line *fb*, which is drawn u ward for this joint. The load or force *BC*, 8 550 lb, is known and is represente by *bc*. *ch* is drawn parallel to *CH*, and *hf* parallel to *HF*, closing the polygo The length of *ch* determines the magnitude of the stress in *CH* and *hf* the stre in *HF*. The stresses in all the truss-members but *HP* are now determine This stress is found by considering the force and stresses acting at joint 7. A this joint the force *PQ*, or 3 650 lb, and the stresses in *QE*, *EF* and *FH*, represente respectively by *pq*, *qe*, *ef* and *fh*, have been determined. The line *hp*, represen ing the stress in *HP*, completes the polygon for joint 7. Hence *hp* determin the stress in *HP*, and as *ho* is drawn from left to right, from the joint, *HP* is i tension. With reference to joint 3, the line *ch* is drawn towards joint 3 an hence *CH* is in compression. Scaling the lines in the stress-diagram (Fig. 12A the figures shown by the side of the lines are obtained. They indicate the ma nitude of each stress in pounds, the + sign denoting compression, and the − sig tension. The two foregoing examples illustrate the method of drawing th stress-diagrams for simple symmetrical trusses, symmetrically loaded. Th truss-diagrams should be drawn in accordance with the measurements give

le of not less than ⅛ in to the foot; and the stress-diagram should ine by line, in accordance with the foregoing directions and the ined and compared with those given in the figures. A variation of lb for small stresses and less than 1% for large stresses may be ex- a greater variation indicates either that sufficient care has not been drawing the stress-lines exactly parallel to the corresponding lines diagram, or that an error has been made in drawing the truss-dia- scaling the lines of the stress-diagram. After these two examples orked, a number of the following examples, also, should be solved, nciples are fully understood.

r **Museum of Fine Arts, St. Louis, Mo. Example 3.** Fig. 13 ne truss-diagram of the truss shown in Fig. 11, Chapter XXVI,



. 13. Truss-diagram. Museum of Fine Arts, St. Louis, Mo.
Fig. 13A. Stress-diagram

ated being approximately those due to the roof and suspended The loads being symmetrically disposed, each supporting force is alf the total load, or 41 040 lb. The counterbraces *CC*, shown VI, are omitted from the truss because they have no stress when niformly loaded. To draw the stress-diagram (Fig. 13A), first he vertical line *sa*, equal to 41 040 lb, equal to R_1; and then *ab* respectively to *AB* and *BS* and representing the stresses acting joint 2, the line *ba* represents the stress in *BA*; *ac*, equal to 7 200 ; *cd*, the stress in *CD*; and *db* the stress in *DB*. The polygon s the forces in equilibrium acting at joint 2. At joint 3 there are forces; and as three unknown forces out of five in one polygon mined, joint 4, where *dc* and the load *CF* are known, is considered ing off the load *cf*, equal to 12 240 lb, the stresses in *FE* and *ED* determined. These are found by drawing *fe* parallel to *FE*, and *D*, the two lines intersecting at *e*. At joint 3, *sb*, *bd*, *de* and the own, and *eg* and *gq* are drawn to close the polygon *sbdegs*. At

joint 10 the force *pq*, equal to 12 000 lb, and *qg* are known; and *gg'* and *g'p* a drawn to close the polygon. At joint 5, *g'g*, *ge* and *ef* are known and *ih* and *h* are drawn to close the polygon Since there is no load at joint 5, *f* and *i* fall the same point in the stress-diagram. The stresses in pounds, in the vario members of the truss, are given in numbers on the corresponding lines in th stress-diagram (Fig. 13A).

Triangular Howe Truss. Example 4. Consider the skeleton triangul Howe truss represented in Fig. 14 loaded as shown by the weight of the ro

F

above and a ceiling below. To draw the stress-diagram, first draw to sc the supporting force *qj*, equal to 46 620 lb. Then lay off *jk* equal to 10 320 *kl* equal to 10 320 lb, etc. Then draw the lines *ja* and *aq*, and the three for at the left support are known. At joint 0, *pq* and *qa* are known and *ab* and are drawn to close the polygon. At joint 1, *ba*, *aj* and *jk* are known and and *cb* are drawn to close the polygon. At joint 2, *op*, *pb* and *bc* are kno and *cd* and *do* are drawn to close the polygon. At joint 3, *dc*, *ck* and *kl* are kno and *le* and *ed* are drawn. At joint 4, *no*, *od* and *de* are known and *ef* and *fn*

se the polygon. At joint 5, *fe*, *el* and *lm* are known and *mg* and *gf*
Joint 7 is considered next, for at joint 6 there are three unknown
d by the graphic method three out of five forces, meeting in a point
ibrium, must be known in order to determine the other two. At

at joints are about as indicated in Fig. 15. To draw the stress-
15A), first construct the force-polygon by laying off to scale in
xternal forces, commencing with the left reaction 34 200 lb. Next,
t joint 0, the supporting force *sa* is known, the stress in the rafter
stress in the tie *ps*, closing the polygon. At joint 1, *pa* and *ab*

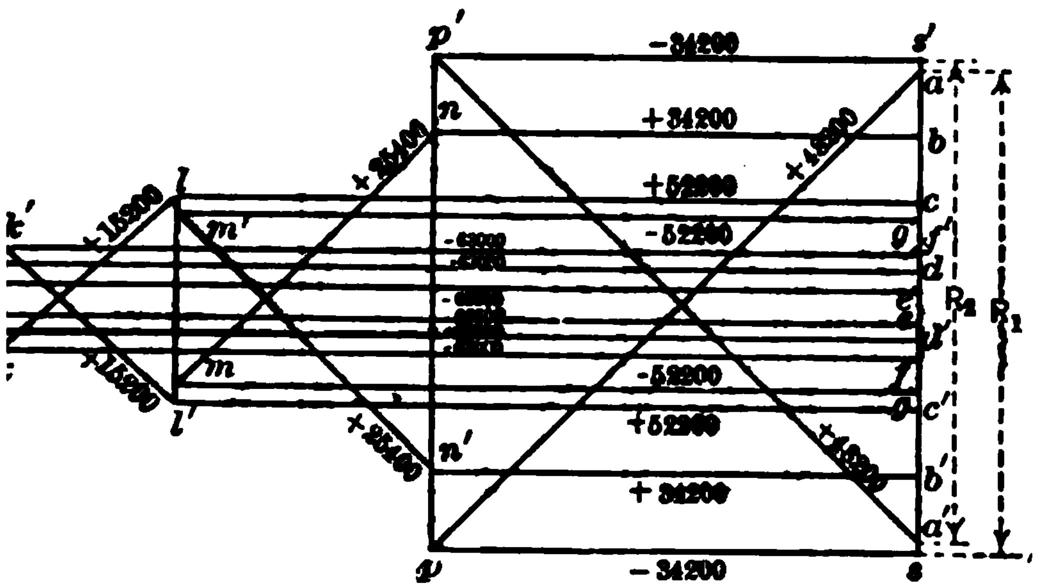

Fig. 15A. Howe Truss. Stress-diagram

bn and *np* are drawn, closing the polygon. At joint 2, *gs*, *sp* and
nd *nm* and *mg* are drawn. At joint 3, *mn*, *nb* and *bc* are known
re drawn. The stresses at the remaining joints are found in the
ose at 3 and 4. The stresses in pounds in the various members
noted in figures in the stress-diagram (Fig. 15A).

Loaded at Alternate Joints. Example 6. (Fig. 16.) This
owe truss is selected to show how to proceed when there is no

load at one or more of the joints. Fig. 16 represents the center lines of a trus 50 ft in span and only 5 ft in height. In order to give the braces an inclinatio approximating 45°, the truss is divided into ten panels; but purlins are place over every other joint, as in Fig. 16, Chapter XXVI. The loads from thes purlins are about 5 000 lb. The stresses at joint 1 are found in the same mann as in the previous example, always starting with the supporting force. A joint 2 the stress-line *da* is already drawn; and as there is no load at this joint

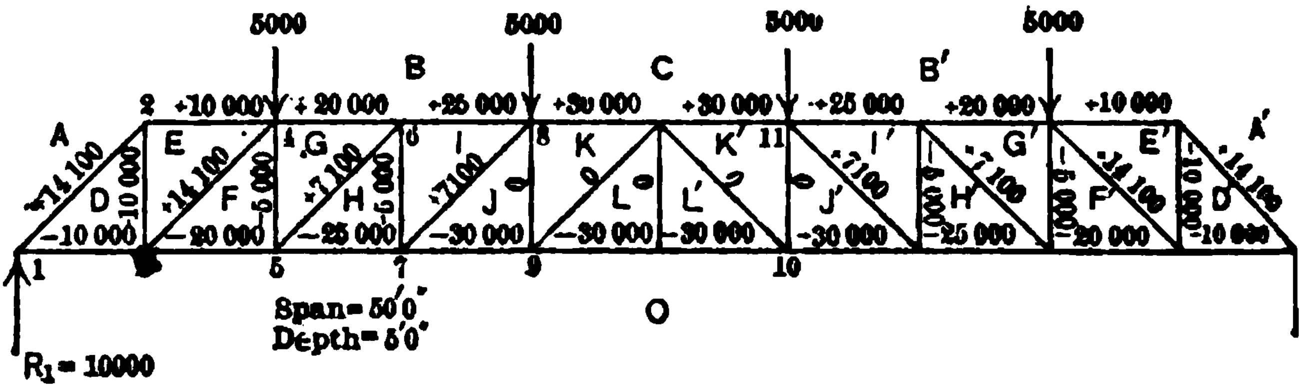

Fig. 16. Howe Truss. Truss-diagram

a line is drawn from *a* parallel to *AE* (*A* covers the entire space from joint to joint 4), and a line from *d* parallel to *ED*, the two lines intersecting at *e*.

The force-lines and stress-lines are as follows:

At joint 3: *od*, *de*, *ef* and *fo*;
At joint 4: *fe*, *ea*, *ab*, *bg* and *gf*;
At joint 5: *of*, *fg*, *gh* and *ho*;
At joint 6: *hg*, *gb*, *bi* and *ih*;
At joint 7: *oh*, *hi*, *ij* and *jo*;
At joint 8: *ji*, *ib*, *bc* and *ck*;

the latter line extending to the point of beginning, *j*, showing that there is n stress in *kj*. At joint 9 the only stresses are *oj* and *lo*, for as there is no stre

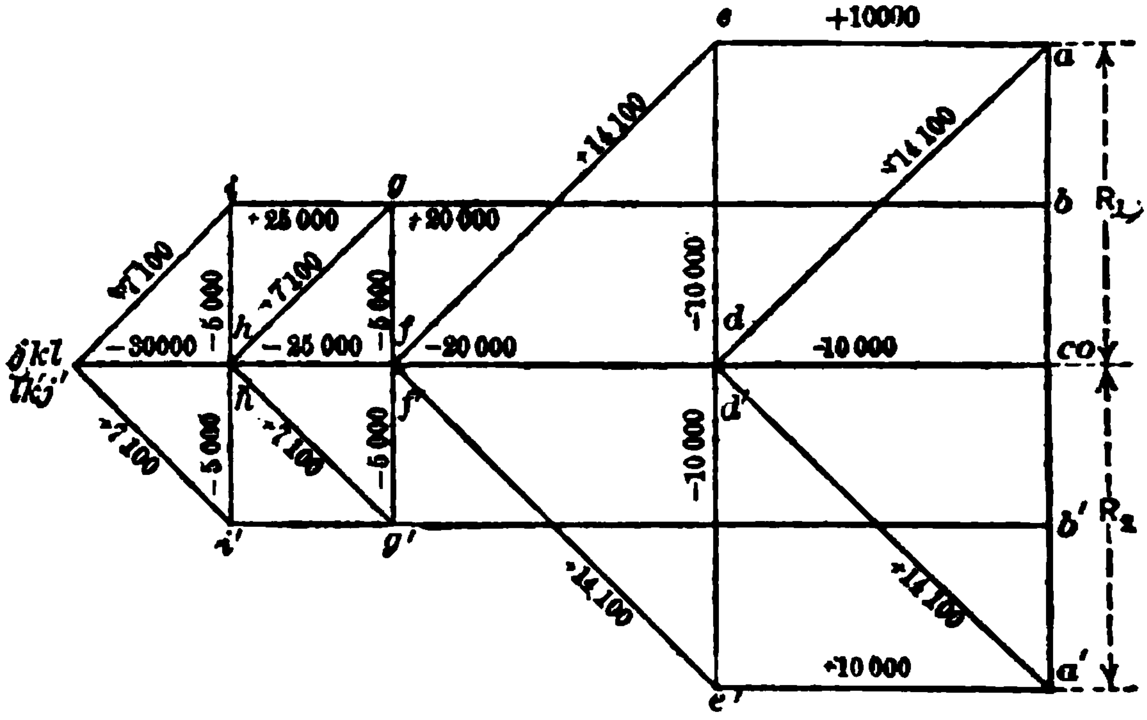

Fig. 16A. Howe Truss. Stress-diagram

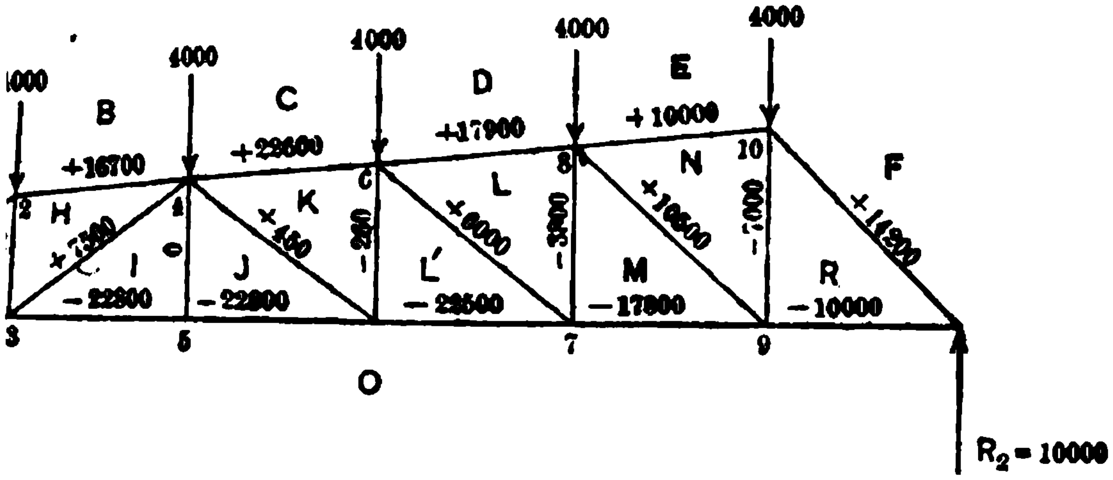
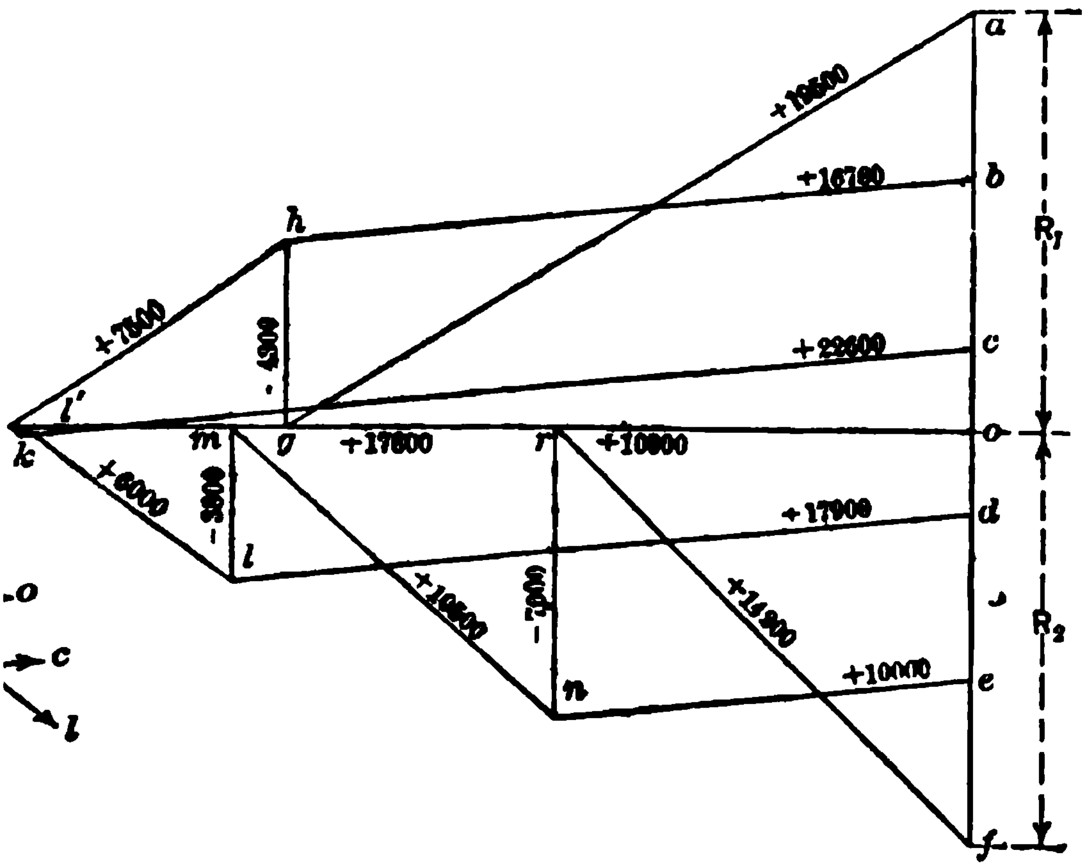
in *JK*, for equilibrium there can be none in *KL*. There is, also, no stress in th middle rod. Although these members have no stress, it is advisable to inse them in the truss in order to stiffen the top and bottom chords. They m be made very light, say ½ in in diameter for the rods and 3 by 6 in in cro section for the braces.

russ with Slanting Top Chord. **Example 7.** In order to give a roof it is often desirable to incline the top chord of a HOWE TRUSS ', Chapter XXVI. Fig. 17 shows the truss-diagram for such a truss, A the stress-diagram. The latter is drawn in the same way as the ım in Example 5, but because the top chord is not level, the stress- ıot symmetrical. When the stress-diagram is not symmetrical it is complete the entire diagram, so as to show the stress in every mem- ıss. The stress-lines for joint 9 are *om*, *mn*, *nr* and *ro*. This leaves



. 17. Howe Truss with Slanting Top Chord. Truss-diagram



ı. Howe Truss with Slanting Top Chord. Stress-diagram

:o complete the diagram; and if the diagram has been correctly ning *r* and *f* will be exactly parallel to *RF*. There is no stress

Inclined Ties. **Example 8.** (Fig. 18.) This truss has the as the truss shown in Fig. 14, but the diagonals incline in the n and are in tension, while the verticals, except the middle one, ›ression. This form of truss is sometimes used in wooden con- d the long middle braces shown in Fig. 14. Long ties are, as a

rule, more economical than long struts. The construction of the stress-diagr requires no additional explanation after that given for the stress-diagram Fig. 14A. The student should compare the magnitude of the stresses scal and marked in Fig. 18A with those in Fig. 14A, and note the effect of the chan in the direction of the braces. The truss represented by Fig. 14 requires a ve much larger rod in the middle than is required for KL and $K'L'$ in the truss Fig. 18. The middle rod for the truss shown in Fig. 18 may be made very lig

Fig. 18. Pratt Truss. Inclined Ties. Truss-diagram

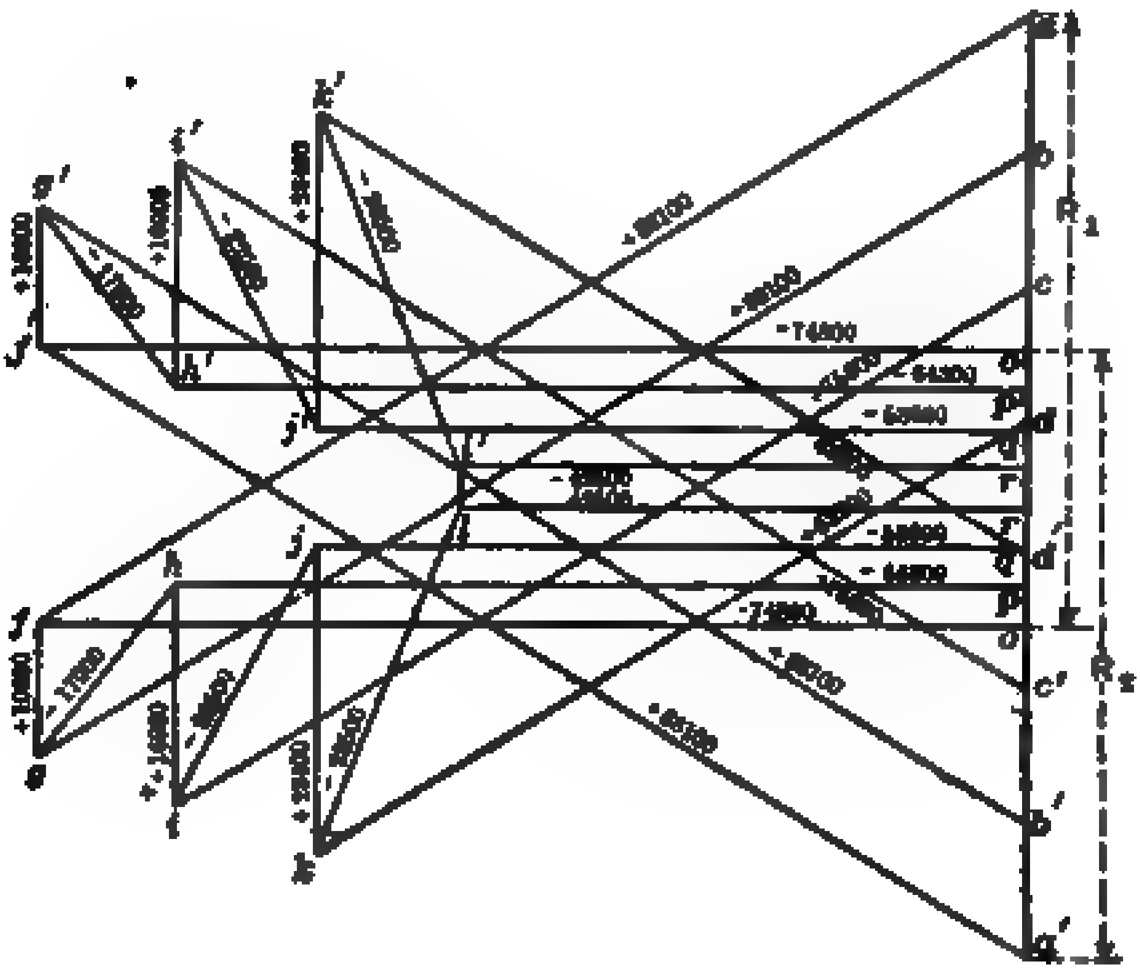


Fig. 18A. Pratt Truss. Inclined Ties. Stress-diagram.

This truss, however, requires, for good construction, special cast-iron wash for the rods.

Simple Fan Truss. **Example 9.** (Fig. 19.) This figure shows the skele of a simple FAN TRUSS with rafters inclined 30° and divided into three eq panels, making the loads AB, BC, CC', etc., equal. The stress-diagram drawn according to the principle already explained and requires no spe treatment. As the loads are equal, the stresses in this truss may be rea figured by means of Table X, and the student should compare the stresses t determined with those obtained by scaling the stress-diagram.

d Fink Truss. Example 1a. (Fig. 20.) The inclination of the ° and the distance between the trusses 20 ft. The loads are cal- a slate roof on boards or on angle-iron purlins. Commence the m by drawing a vertical line equal to the supporting force R_1, or d lettering the lower end of the line *o* and the upper end *a*, as these

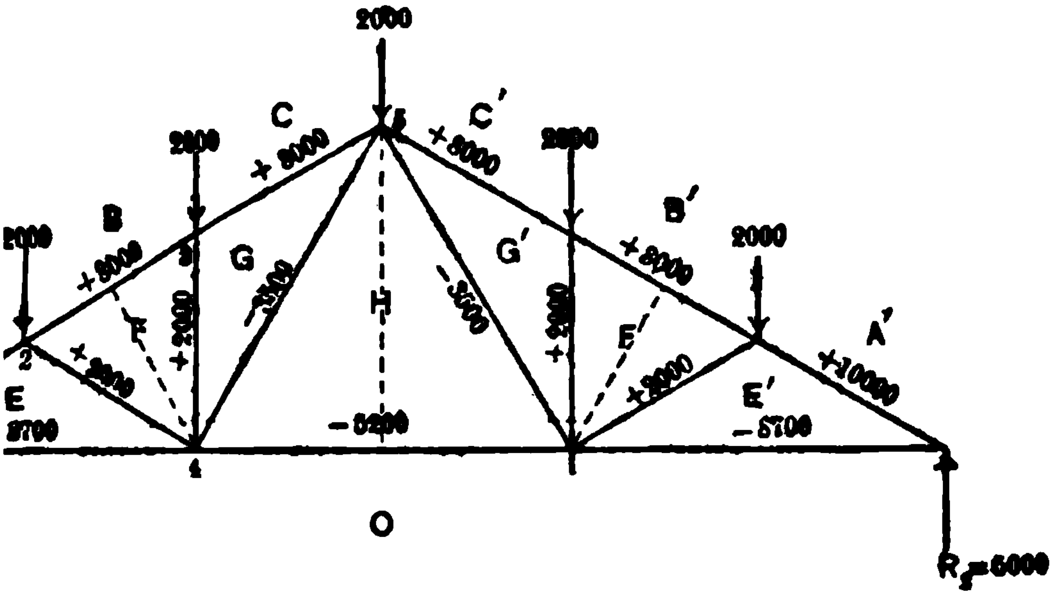

Fig. 19. Fan Truss. Truss-diagram

on each side of the supporting force at joint o. *an* and *no* are to *AN* and *NO*. For joint 1, *na* is drawn upward; *ab* is laid off ı lb and *bm* and *mn* are drawn parallel to *BM* and *MN*. At joint 2 : known, and *ml* is drawn parallel to *ML*, the sides of the stress- *on*, *nm*, *ml* and *lo*. At joint 3 a new condition is met, which is ay of the preced- and which is is form of truss, arently unknown a study of the however, it is and *IK* act as -RODS, taking up ı the lower ends t joints 2 and 5; s at joints 1 and *NM* and *IH* are h, the stress in as the stress in already known. :he number of at joint 3 to force known at the next *mb* and al to 16 100 lb.

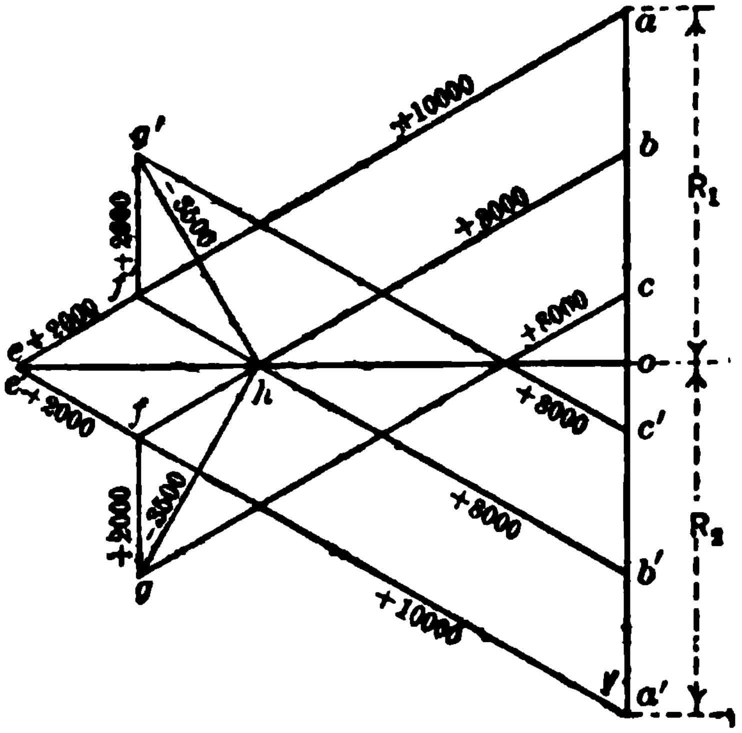

Fig. 19A. Fan Truss. Stress-diagram

s drawn parallel to *CI* and from *l*, the initial point, a line Between these two lines there must be a line, *ik*, parallel to ; length to *ml*; and this line is determined by means of the arallel ruler and straight-edge. If correctly drawn, the joint *i* ith *nm*. The sides of the stress-polygon for joint 3 are, then, and *kl*.

At joint 4 the stress-lines are *ol*, *lk*, *kg* and *go*.
At joint 5 the stress-lines are *gk*, *ki*, *ih* and *hg*.
At joint 6 the stress-lines are *hi*, *ic*, *cd* and *dh*.

If the stress-diagram is accurately drawn, a line from *d* parallel to the ra will pass through the point *h*. The vertical tie *GG'* (Fig. 20) has no st and its only purpose is to prevent the horizontal tie from sagging.

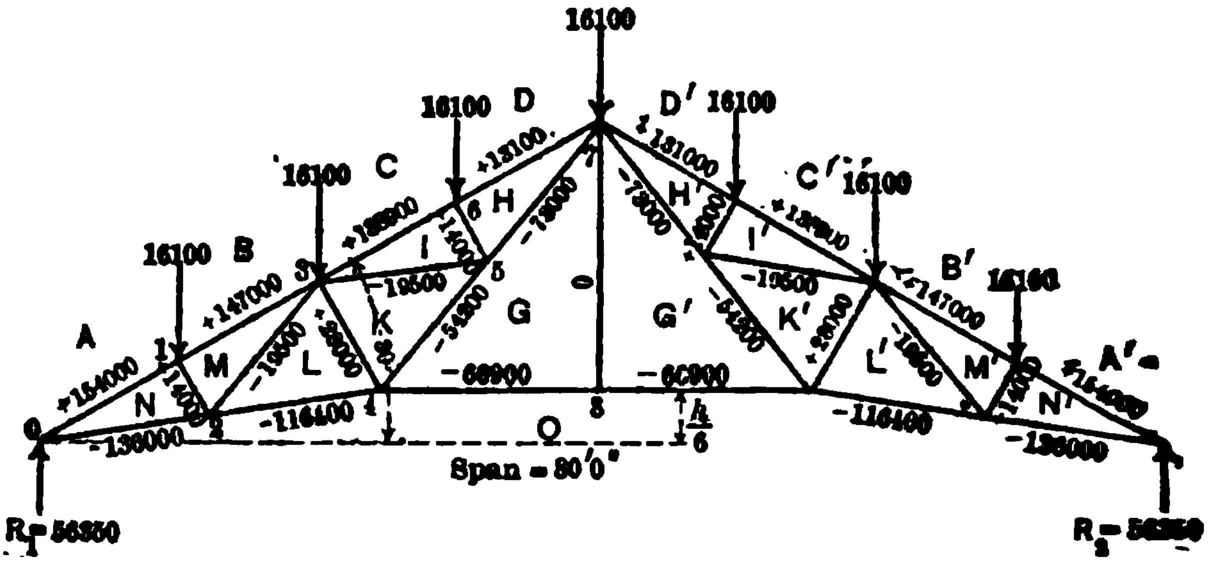

Fig. 20. Cambered Fink Truss. Truss-diagram

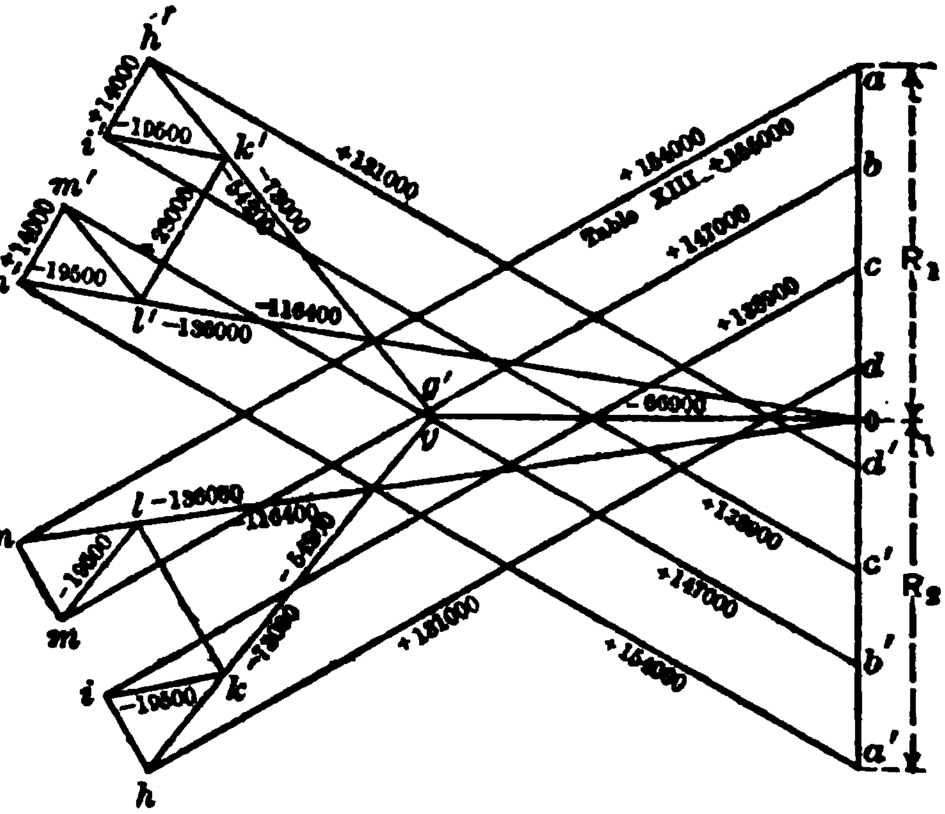

Fig. 20A. Cambered Fink Truss. Stress-diagram

Cambered Fink Truss. Example 11. (Fig. 21.) This is the truss sh in Fig. 20, with two additional loads. Steel trusses of this shape are required to support loads from below. In Fig. 21 there are two loads of 4 each, supported at joints 5 and 9, in addition to the roof-loads. The st diagram is drawn in exactly the same way as in Fig. 20A, except that at jo the first-known force *ro*, parallel to *RO*, 4 tons, is laid off, locating *r*. At joint, then, *ro*, *ol* and *lk* are known and *kg* and *gr* are drawn to close the poly It should be noticed that the stresses in *NM*, *IH*, *ML*, *KI* and *LK* not affected by the ceiling-load. This is evident by comparing Fig. 21A Fig. 20A. All of the other stresses, however, are increased becaus the increase in the supporting forces, the greatest increase being in *KG* and

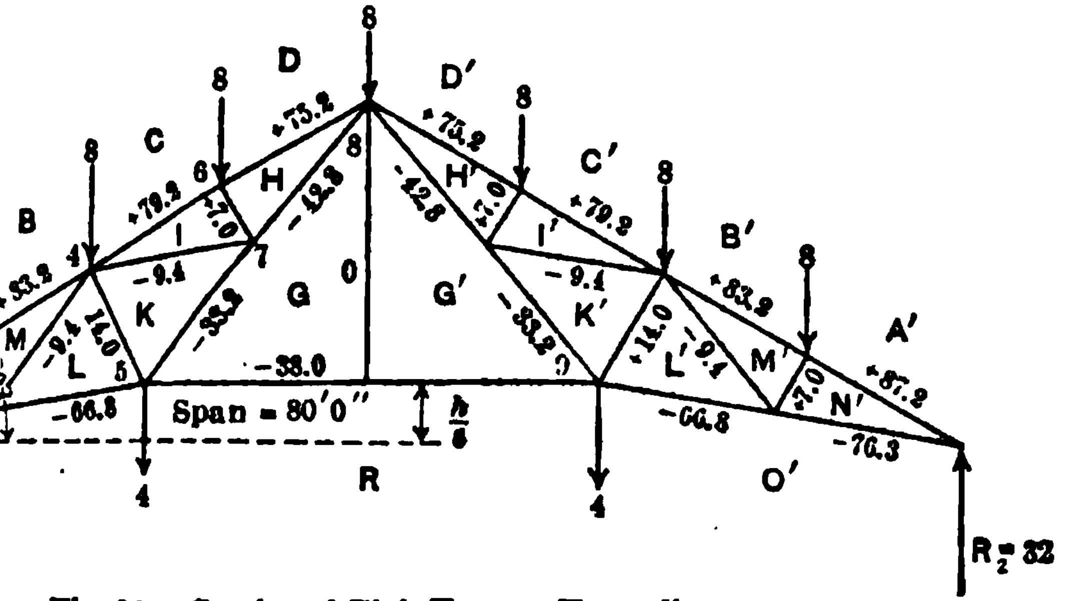

Fig. 21. Cambered Fink Truss. Truss-diagram

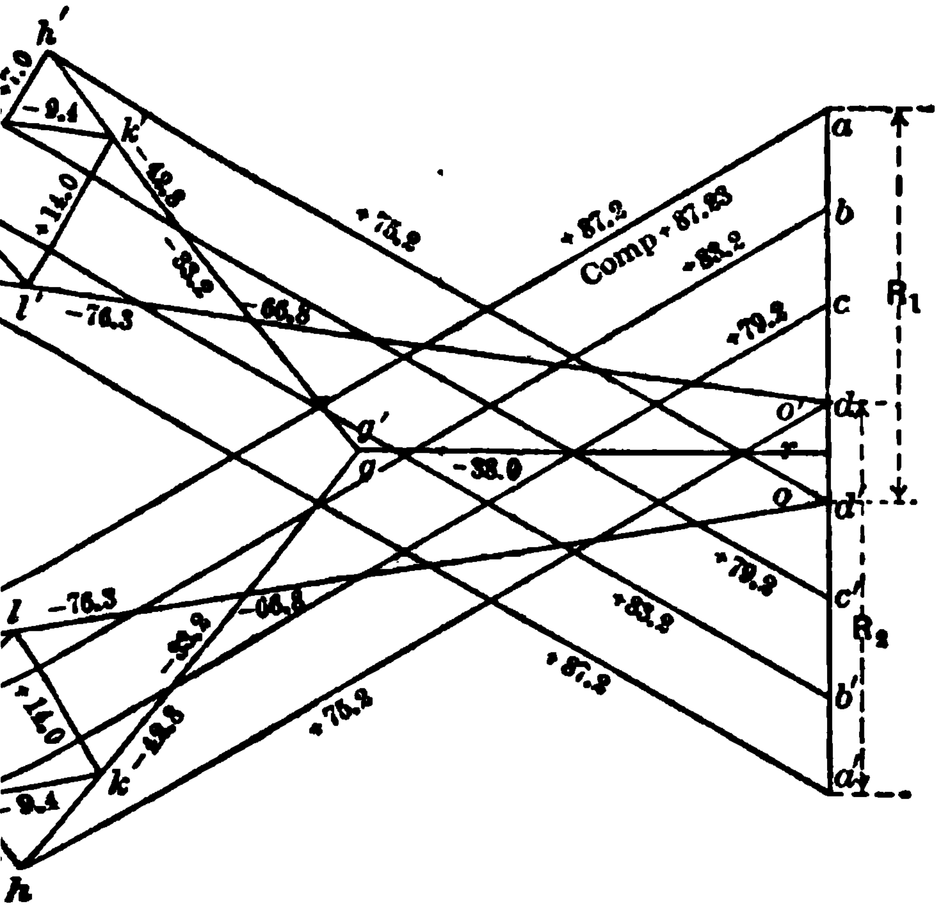

Fig. 21A. Cambered Fink Truss. Stress-diagram

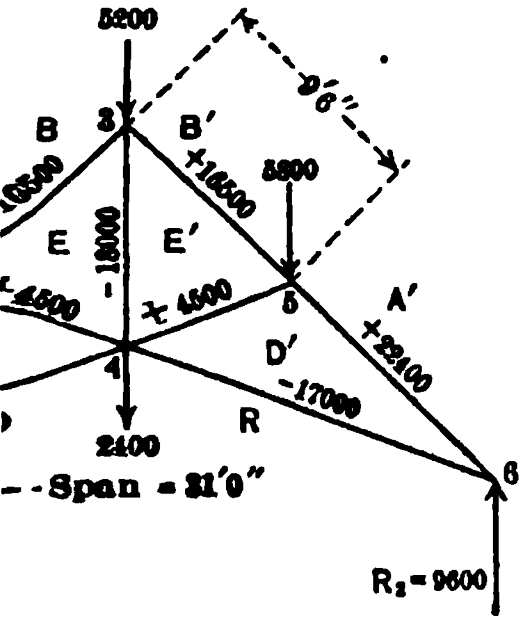

...ors Truss. Truss-diagram

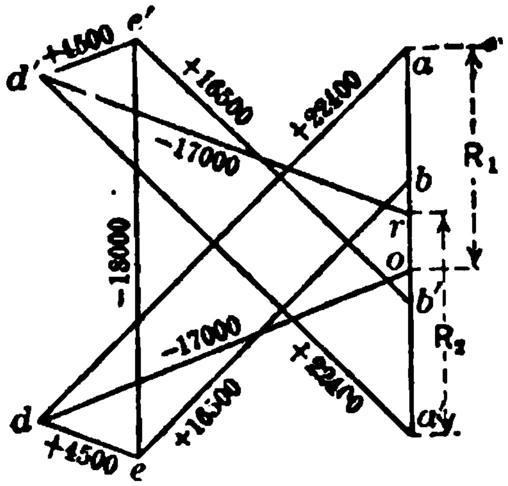

Fig. 22A. Scissors Truss. Stress-diagram

Simple Scissors Truss. Example 12. (Fig. 22.) This is the tru diagram of the truss shown in Fig. 22, Chapter XXVI, which is the simplest fo of the SCISSORS TRUSS. The truss-diagram is drawn by commencing with t line *oa* equal to the supporting force, 9 600 lb, and then in order the forces *bb'*, *b'a'*, *a'r* and *ro*, forming the polygon of the external forces. At joint 1, is known and *ad* and *do* are drawn, closing the polygon. At joint 2, *da* and are known and *be* and *ed* are drawn, closing the polygon. At joint 3, *eb* and are known and *b'e'* and *e'e* are drawn. This determines the stresses in one-h the truss. Those for the other half are, of course, of the same magnitude a character, but the stress-diagram should be continued for the second half of t truss as a check.

Scissors Truss. Example 13. Fig. 23 is the truss-diagram of the tru shown in Fig. 23, Chapter XXVI, with the loads figured about as they wou

Fig. 23. Scissors Truss. Truss-diagram

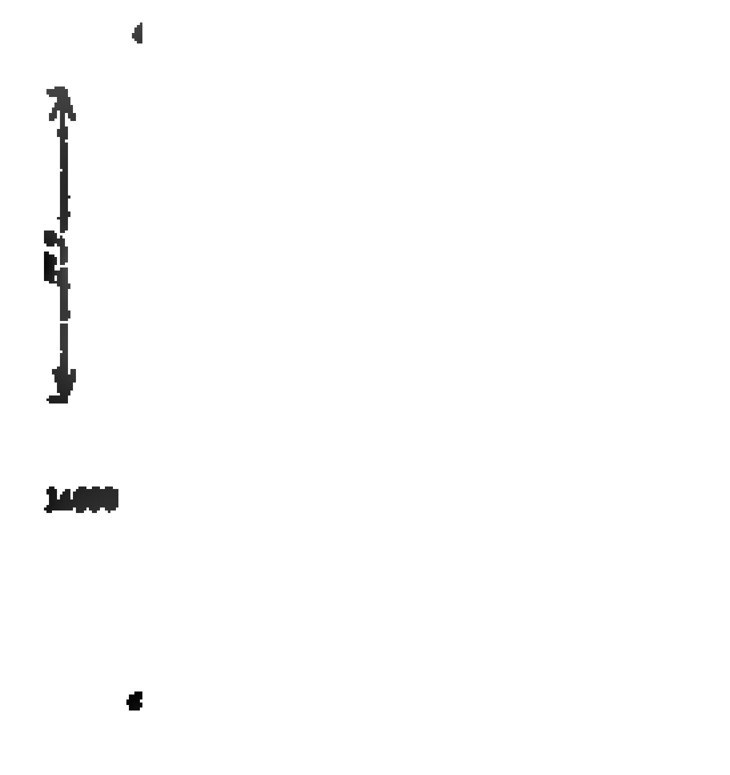

Fig. 23A. Scissors Truss. Str diagram

be for a slate roof and wooden ceiling and for a spacing of 12 ft on centers. T stress-diagram is begun by drawing the line *oa* equal to the supporting fo at joint 1 (14 600 lb). The sides of the stress-polygons for the different joi are as follows.

At joint 1: *oa*, *ae* and *eo*;
At joint 2: *ea*, *ab*, *bf* and *fe*;
At joint 3: *oe*, *ef*, *fh* and *ho*;
At joint 4: *hf*, *fb*, *bk* and *kh*;
At joint 5: *ro* (1 100 lb), *oh*, *hk*, *kl* and *lr*;
At joint 6: *lk*, *kb*, *bc* (5 400 lb), *cm* and *ml*;
At joint 7: *mc*, *cc'* (5 400 lb), *c'm'* and *m'm*.

The student should notice how much the stresses in the principal member this truss exceed the supporting forces or loads, and particularly the great st in the middle rod. For these reasons this is not an economical type of trus spans exceeding 36 ft.

Example 14. Fig. 24 is the truss-diagram of the truss
e 1056, and for which the roof and ceiling-loads are computed
1055. The truss shown in Fig. 4 is built of planks spiked
, but the stresses are found in precisely the same way if the
ivy timbers and supports a greater roof-area. It should be
ly the shape of the truss and the loads, including their point
:t the stress-diagram. The stresses at joints 1 and 2 are
nencing with *oa*, equal to R_1. At each of joints 3 and 4,
three unknown forces. We cannot obtain the stresses at
cting at joint 3 have been determined. The known forces
, equal to 430 lb, and the stresses acting in *OE* and *EF*; and
those acting in *FH*, *HK* and *KR*. *HK* and *KR* are in ten-
old joint 3 from falling down and outwards. Either one,
e omitted, and the greater the stress is in one the less it is in
' way to complete the stress-polygon for joint 3 is to fix the

in and $H = 0.05062 + 0.00002562 = 1975$, or, approximately, is shows that the span would lengthen about 1/20 in, if allowed free one end; or, if fixed, there would be a HORIZONTAL FORCE of ng to push the supports out. In column 4 it is seen that the uare inch are only about one-tenth of those permissible. Assumads become 10 000 lb at each apex-joint, the HORIZONTAL DEFLEC- about 1/5 in, and the HORIZONTAL THRUST becomes 20 000 lb. nclusively that a large excess of material must be employed in the s, particularly in the members EM and HM which contribute over alue of D as shown in column 7, if the HORIZONTAL DEFLECTION is small that its effect may be neglected. As stated before, if the ted to deflect horizontally until fully loaded, the walls or supports bly no HORIZONTAL THRUST to resist.

ner-Beam Truss. As usually constructed the HAMMER-BEAM ted to exert more or less HORIZONTAL PRESSURE at the supports; vided for by heavy walls and buttresses. The diagram of such n in Fig. 27, in which the CURVED BRACES usually built in the the truss are not shown, as they are considered to be purely orna- vertical loading have no stresses. The brace OM is drawn as straight; but a curved brace may be used instead, without alter- n. The stress in the curved piece is that found from the stress- sed by the bending stress due to its curvature. To determine nembers of this truss it is necessary to first find the HORIZONTAL truss against the wall. To do this all the truss-members from 4 are considered to form a FRAMED BRACE, OF ASSEMBLAGE OF ng the upper portion of the truss at joint 4, or a SINGLE BRACE, oken line o4, Fig. 27, is assumed to have the same effect on the pieces put together in the FRAMED STRUT; that is, the truss is

lb per sq in is used for the value of E for steel the values of D and changed. See Table I, page 664.

considered to have the same HORIZONTAL THRUST as the truss shown in Fig. 26 The load at joint 4 is evidently: 12 000 lb, plus the load at joint 5, plus h the load at joint 6, plus half the load at joint 2; making in all, 36 000 lb. T find the HORIZO TAL THRUST and t stresses the proc dure is as follow ab (Fig. 27B) is la off equal to the lo at joint 2, bc equal the load at joint cd equal to the lo at joint 5, and d equal to the load joint 6. Then t load at joint 4 (Fi 27A) = ½ ab + bc cd + ½ dd'; and if horizontal line drawn from x to t left, and from t center of ab a li parallel to the li 4–0 (Fig. 27A) the

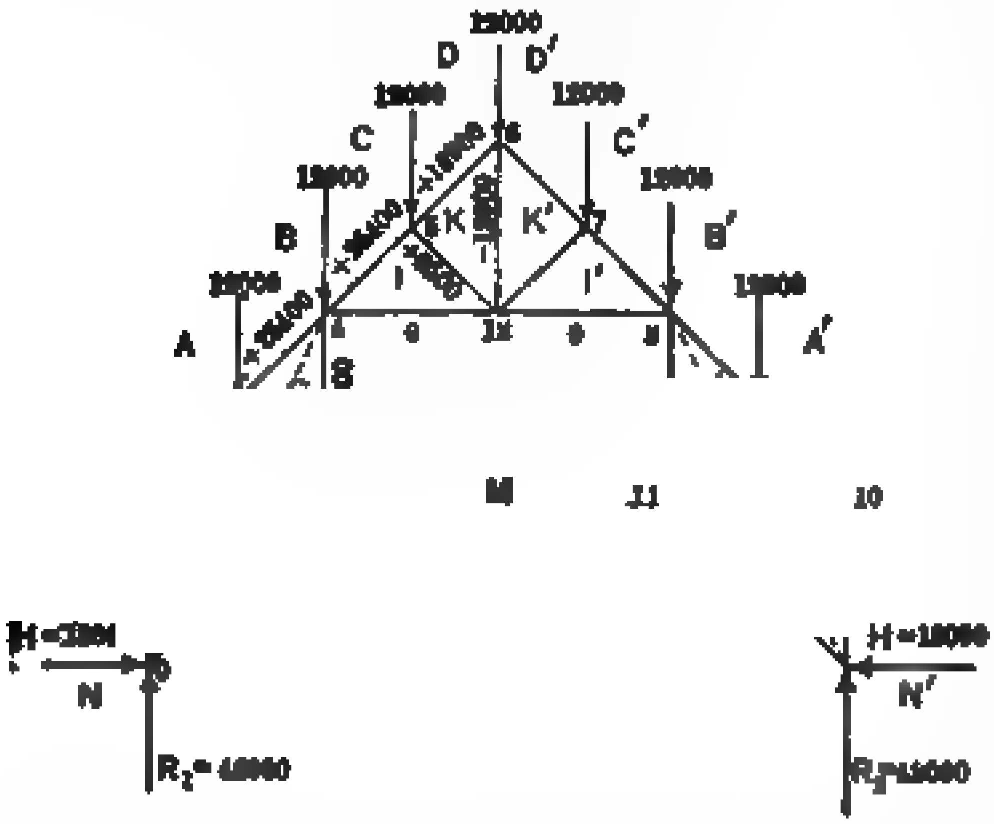

Fig. 27. Hammer-beam Truss. Truss-diagram

two lines will intersect at m, and mx is the MAGNITUDE OF THE HORIZONTA THRUST exerted on the wall at the joint o. Having obtained this thrust, is easy to determine the stresses in the pieces. At joint o the four forces

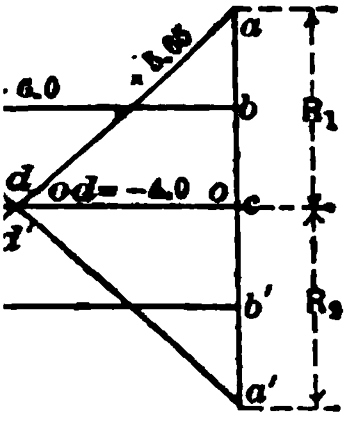
except that due to the weight of the bottom chord. This truss ructed of steel angles. When wood is employed, three or four ses are combined forming the LATTICE TRUSS shown in Fig.
It is entirely unnecessary to use graphical methods in determining the stresses, as the chords and web-members are respectively uniform in size. For the chords the maximum bending moment divided by the distance, center to center, of the chords gives the designing-stress for the chords. The maximum vertical shear, usually the reaction, divided by the number of simple WARREN TRUSSES combined gives the vertical component for which the web-planks are designed. This, of course, leads to a waste of material as far as resisting stresses is concerned, but for stiffness and economy in labor, the extra used. This truss can be extended indefinitely by giving it for the span. (See, also, pages 1008 and 1009.)



n Truss. Stress-diagram

r Truss. Example 20. Fig. 33 is the truss-diagram of a truss own in Fig. 59, Chapter XXVI, the panel-loads being taken at the analysis being the same for any other loads. The stress-

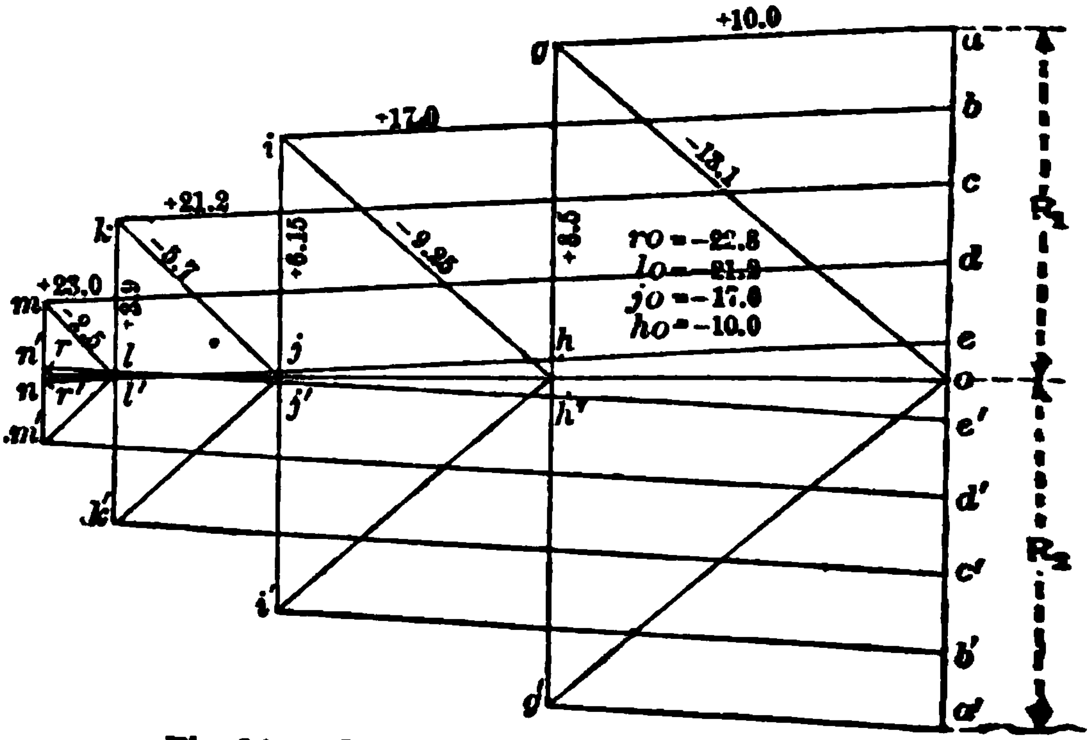

Fig. 34A. Quadrangular Truss. Stress-diagram

lrawn exactly as in the previous examples, commencing with the
orce *oa* and considering the joints in the order in which they are
In this truss the diagonal web-members are all in tension and the
ompression. It will be noticed that the inclination of the diagonals
nels nearest the middle of the truss is opposite to that of the diagonals
anels. This is due to the inclination of the top chord, which causes
stresses in the inner diagonals when they incline the other way.
LM, however, is so small that a single steel angle resists either a com-

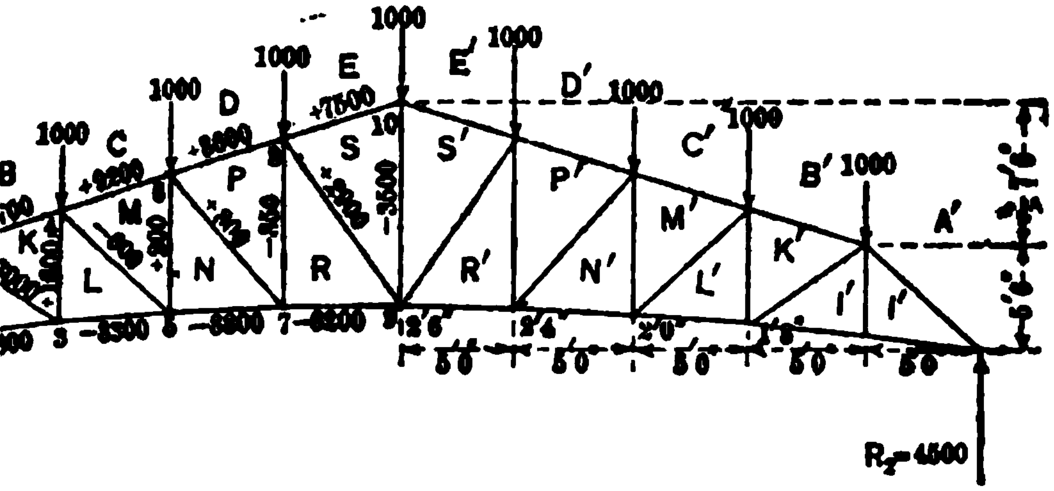

Fig. 35. Quadrangular Truss. Truss-diagram

sile stress. The truss shown in Fig. 34 is very similar to that shown
principal difference being that the slope of the top chord is less
than in the latter. In Fig. 34, the diagonals in the two middle
cline from the top of the middle vertical, and the stress in these
ery small. With a still less inclination to the top chord, the stress
zero; and with a horizontal top chord the character of the stress
sed. To keep it in tension, its direction should be changed, as in
oss, Fig. 28. Comparing the stresses in these two trusses, it is
le the stresses in the

ferent panels, the stress-lines do not lie over each other, but
he lines in the stress-diagram being parallel to the corresponding
ss-diagram. In this truss the character of the stresses in the
embers is reversed in the two panels nearest the middle. Thus
stress-polygon for joint 4 are *lk*, *kb*, *bc*, *cm* and *ml*, the stress *ml*
joint and hence denoting tension. At joint 8 the sides of the
re *rp*, *pd*, *de*, *es* and *sr*, the latter line acting towards the joint,
ting compression. Under irregular loading, the character of
would probably be reversed, so that the piece would be in ten-

sion instead of in compression. The stresses in members of trusses like Figs. 3
34 and 35 should, therefore, always be computed for snow on one-half of t
truss only and also for wind-pressure.

Quadrangular Truss. Example 22. In Fig. 36 is shown the diagram
the truss illustrated in Fig. 65, Chapter XXVI. This truss is similar to th
shown in Fig. 34, except for the secondary bracing in the panels and for t

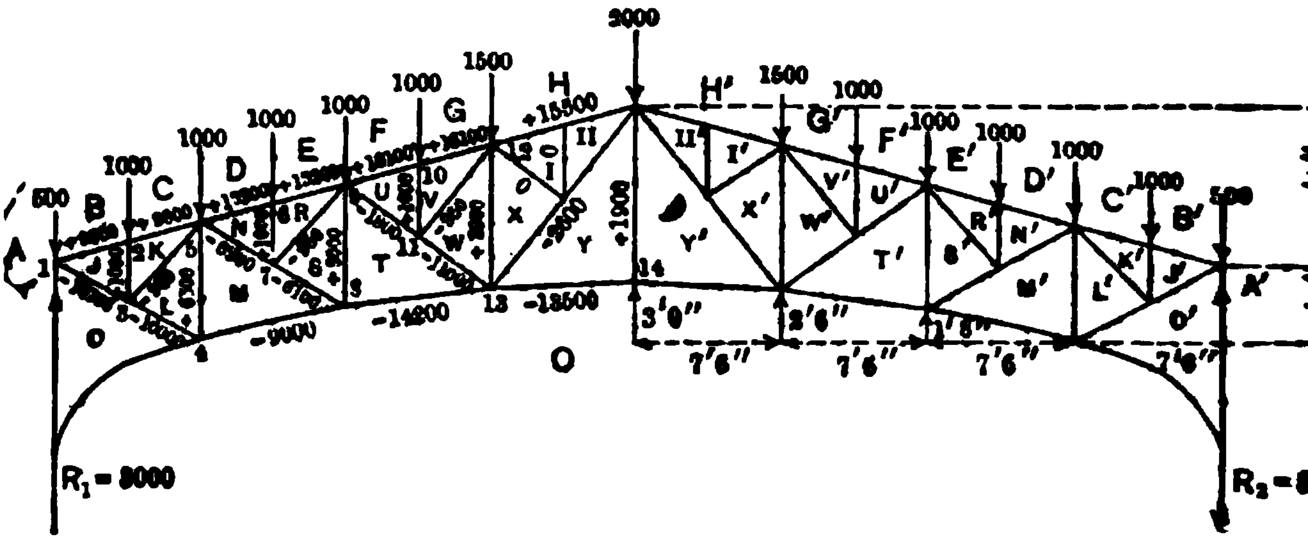

Fig. 36. Quadrangular Truss. Truss-diagram

curved bottom chord. The stress-diagram presents no difficulties. In drawi
the lines from *o* parallel to the members of the bottom chord the latter sho
be considered as made up of straight lines connecting the joints. Thus *os*
drawn parallel to an imaginary straight line connecting joints 8 and 4. As th
is no load over the center of the two panels next to the middle of the truss, th
are no stresses in the truss-members between *X* and *I* and *I* and *II*. Wh
the bottom chord is straig
as in Fig. 34, there is

example, the top chord is curved and is the only piece that is in compressi
All the other members are in tension. Under a steady load only, such as t
weight of the roof itself, the diagonals drawn with solid lines and placed
shown in Fig. 37 are all that are needed; but when there is a severe wind-pr
sure on one side of the roof only, it is necessary to have the additional set
diagonals shown by the dotted lines. These COUNTERBRACES, as they

lled, forming the additional set, are not stressed when there is a vertical load ly and they are omitted in drawing the stress-diagram. To draw the stress-agram, the loads are laid off on a vertical line, as in all the previous examples, e point *o* being half-way between *e* and *e'* (Fig. 37A). *oa* is the supporting ce at joint 1. In drawing the stresses at the different joints, those at joint 1 e first drawn and then those at joints 2, 3, 4, 5, etc., in the order in which they e numbered (Fig. 37). In the stress diagram, *oa*, equal to the supporting

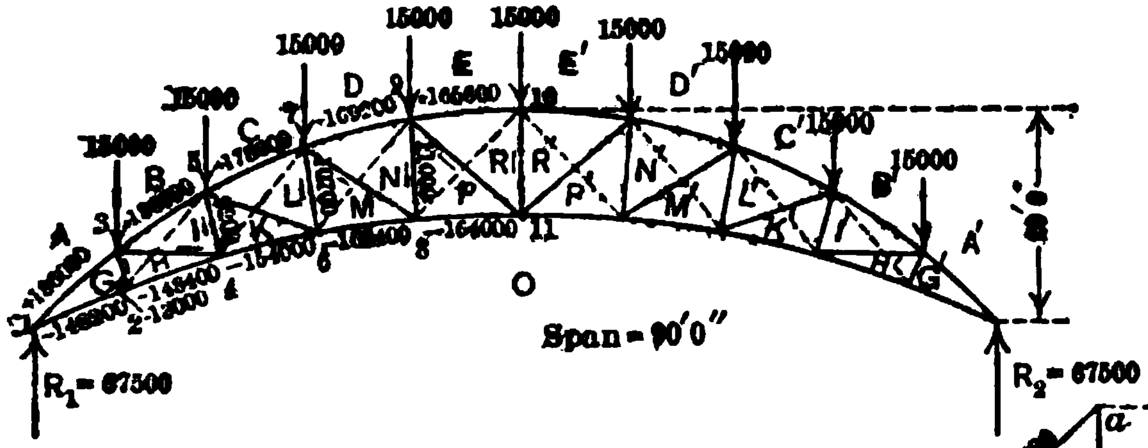

Fig. 37. Bowstring Truss. Truss-diagram

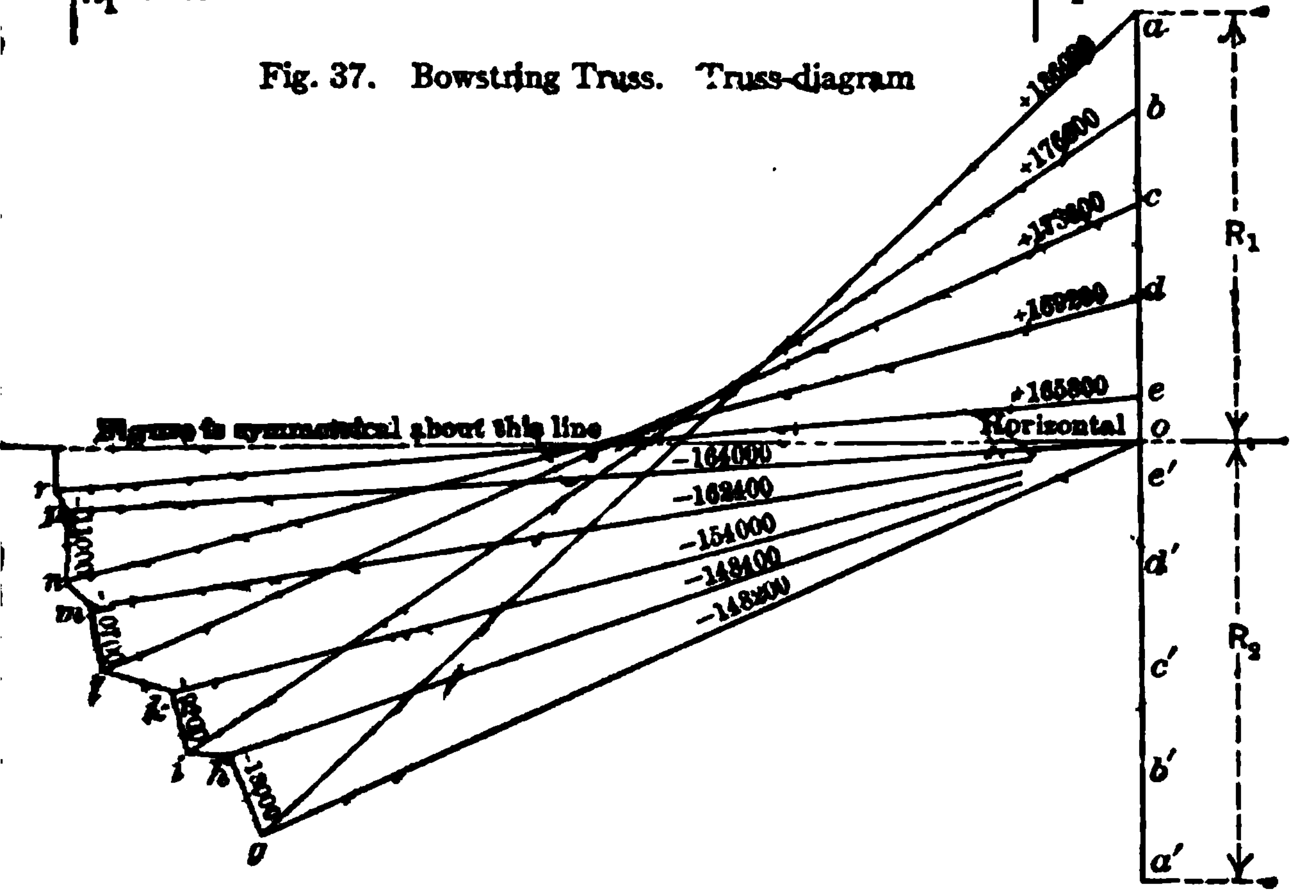

Fig. 37A. Bowstring Truss. Stress-diagram

e at joint 1, is known and from *a* a line is drawn parallel to *AG*, and from line parallel to *GO*. These two lines intersect at *g*. The lines repre-ing the stresses in the curved members of the truss are drawn parallel traight lines connecting the two ends of each curved piece. Thus *ag* is n parallel to 1–3 and *og* parallel to 1–2. At joint 2, *og* is known, *gh* is drawn llel to *GH* and *ho* parallel to *HO*. At joint 3, *hg* and *ga* have been drawn, ed *ab* is known and *bi* and *ih* are drawn. At joint 4, *oh* and *hi* have been n, and *ik* and *ko* are next drawn to close the polygon. The stress-lines for 6 and 8 are drawn in a similar way, and those for 5, 7 and 9 similarly to at joint 3. After drawing the stress-lines for joint 9, joint 10 is next con-d; and after the stress-lines for that joint are determined the stresses in e members of the truss are known. The stresses in this particular example iven in pounds on the respective lines in the stress-diagram. It will be

noticed that the stresses are very great in the top and bottom chords, but v small in the bracing. The latter stresses are, in fact, so small that it is jus well to make all the diagonal braces the same size and of dimensions suffici to resist the stress in IH, which has the greatest stress; or IH and KL may made the same size and MN and PR a smaller size. The verticals or radiat pieces may all have a sectional area sufficiently large to safely resist the st in NP. The great advantage of this truss lies in the fact that all its parts in tension excepting the upper chord, which, of course, is in compression. T manner in which stresses act may be described in general by saying that upper chord carries all the load, like an ARCH, and is prevented from spread out at the ends by the lower tie; and that the object of the bracing and vertical pieces is only to keep the bottom chord in its curved position.

Trusses Unsymmetrically Loaded. Now that the principles have b explained according to which the stress-diagrams may be drawn for seve

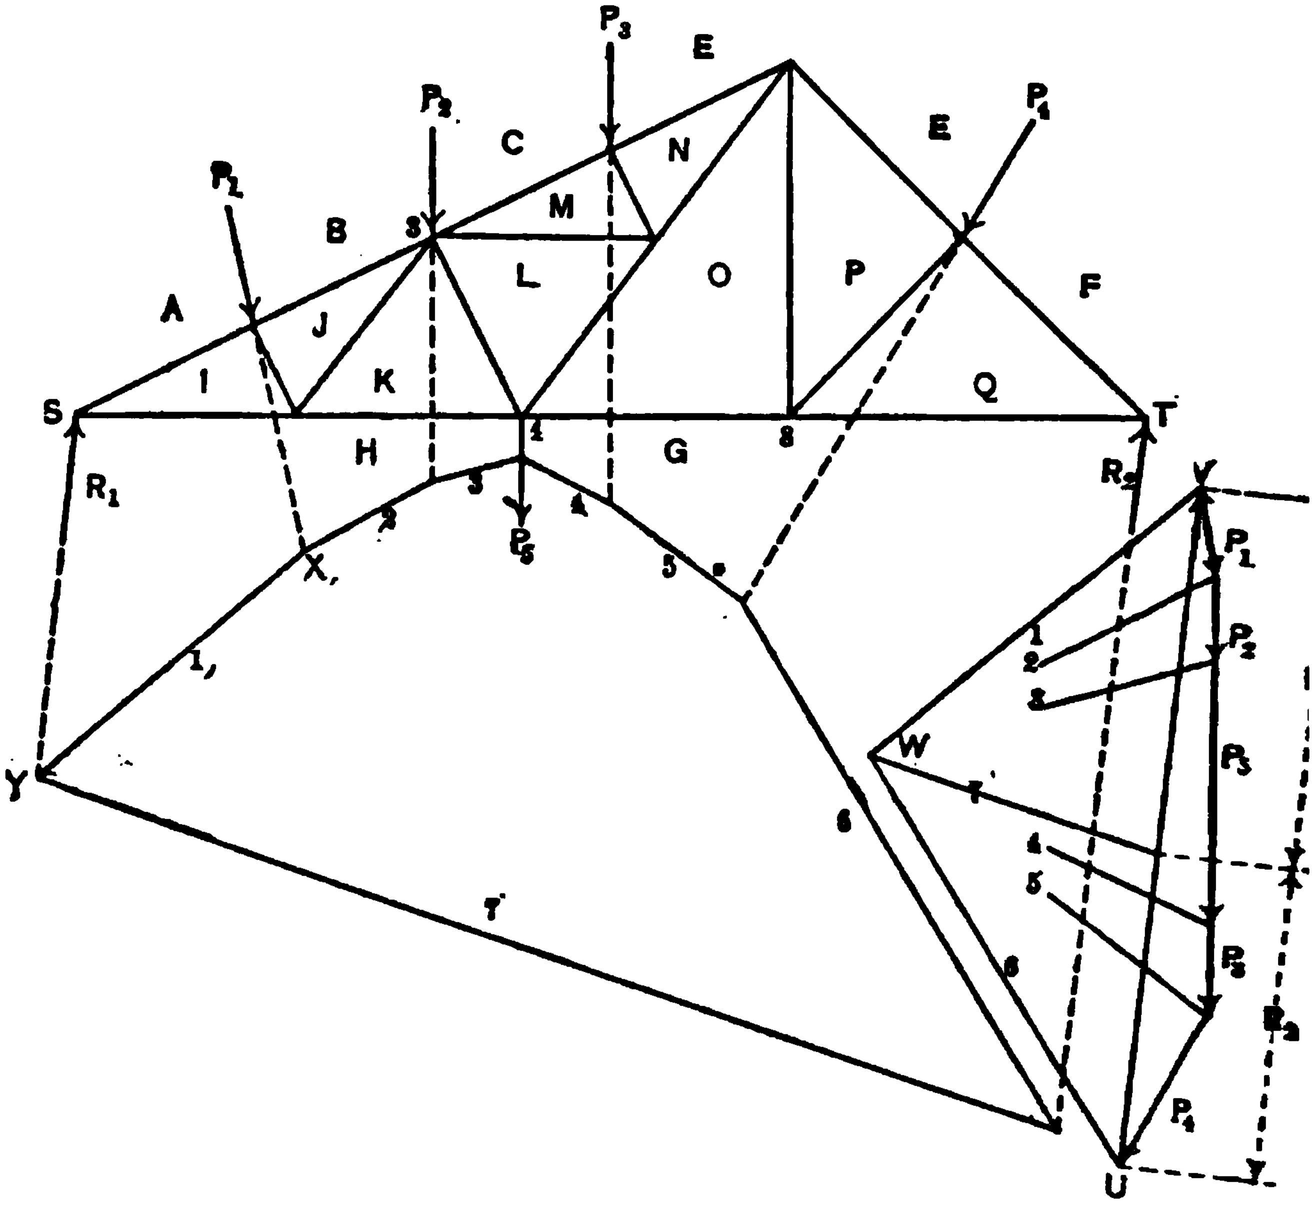

Fig. 38. Unsymmetrical Truss. Truss-diagram

Fig. 38A. Unsymmetri Truss. Force-polygo

forms of trusses SYMMETRICALLY LOADED, it may be well to consider the subj in a more general manner. It will now be assumed that there are no restrictio as to SYMMETRY in the form of the truss and its loading; and, furthermore, will not be assumed that all of the loads act as VERTICAL FORCES as in the proble just solved. Fig. 38 shows an UNSYMMETRICAL TRUSS UNSYMMETRICAL LOADED and with loads or forces which are not parallel. In the previous proble the supporting forces or REACTIONS have been equal and each equal to one-h the load. In this problem such is not the case. The first step, then, is the DETE

THE REACTIONS. If the truss remains in position it follows that
acting upon the truss, such as the LOADS and REACTIONS, must be
UM; also since by definition a TRUSS must act as a BEAM, the truss
aced by a BEAM in considering the OUTSIDE FORCES. In Fig. 38,
lines representing the direction of the forces, as shown, until they
ST and assume ST to be a simple beam loaded with the forces AB,
eginning with AB, to some convenient scale lay off the forces in
vn in Fig. 38A. The broken line VU represents the forces in magni-
rection. For equilibrium, forces equivalent to UV are required.
nt when we remember that the algebraic sum of the vertical and
mponents of all the forces acting must respectively equal zero.
at the supports at S and T, Fig. 38 are similar in every respect we
that the reactions R_1 and R_2 act in the same direction and that they
UV. This does not determine the magnitudes of R_1 and R_2. These
l as follows: In Fig. 38A, assume any point W and draw the lines 1,
Fig. 38, starting at any point on R_1 draw the line 1 parallel to the
38A, and extend it until it cuts the direction or line of action of the
own; from this point draw a line parallel to 2 in Fig. 38A, and extend
the direction of BC as shown, and so continue until line 6 is drawn.

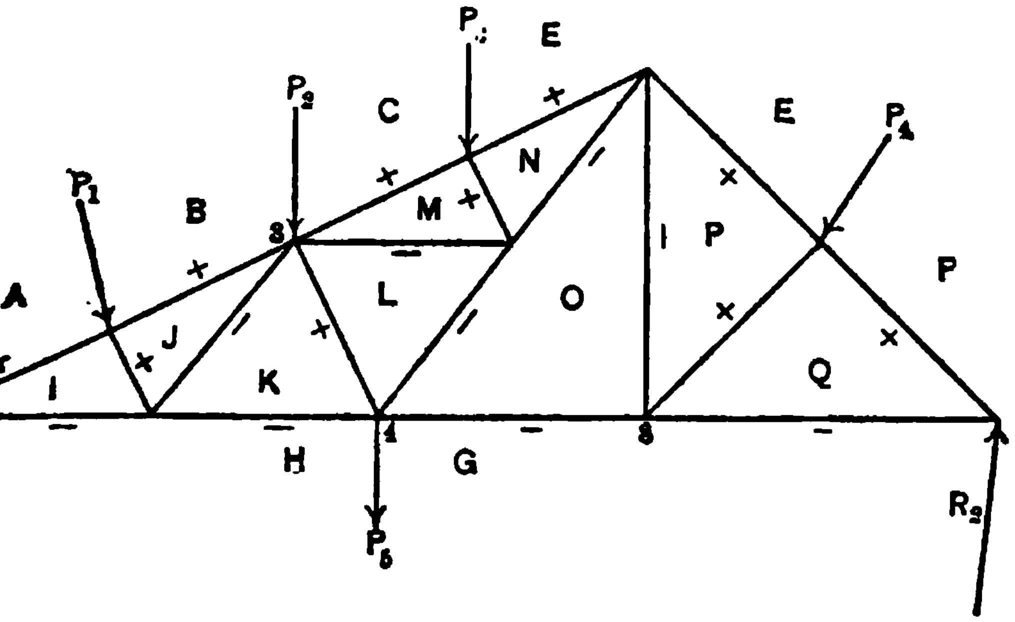

Fig. 38B. Unsymmetrical Truss. Truss-diagram

raw line 7 in Fig. 38 and then in Fig. 38A draw a line parallel to
til it cuts UV. This point divides UV into two parts, the upper
nitude of R_1 and the lower the magnitude of R_2. No trouble will
in applying the above method if the following rule is obeyed to
Fig. 38, the parallels to any three lines in Fig. 38A which form a
meet in a point. For example, in Fig. 38A lines 1, 2, and P_1,
riangle, and in Fig. 38, their parallels meet in the point X. In
is not necessary that the forces AB, BC, etc., be used in order in
onsidering them in order, on a simple beam, makes the graphical
Fig. 38 less complex and avoids many chances of error. The
d above is general and can be used for forces acting in any direc-
rces are parallel then the load-line ab, bc, ce, etc., in Fig. 38A, and
ill coincide; but the method of procedure remains unchanged.
he FORCES acting upon the truss have been determined, for con-
will be shown in character, in Fig. 38B, and the STRESSES in the
osing the truss will be found. First lay off the forces in exact
t they form a CLOSED FIGURE, which must be the case if they are
The lines with arrow-heads in Fig. 38C show this construction,

which checks the values of R_1 and R_2 obtained above. This figure remains t same regardless of the interior arrangement of the truss. The construction the stress-diagram follows the methods given in the previous examples un point 3 is reached. Here there are three UNKNOWNS, *CM*, *ML* and *LK*, and cannot be assumed that *ML* is the same as *JK*, as was done in examples 10 a 11. Let the truss be cut as shown in Fig. 38D, and the actual stresses in the c pieces assumed to act against the cut ends, then the frame shown in Fig. 3 and the forces R_1, *AB*, *BC*, *CE*, *EN*, *NO*, *OG* and *GH* will be in equilibriu

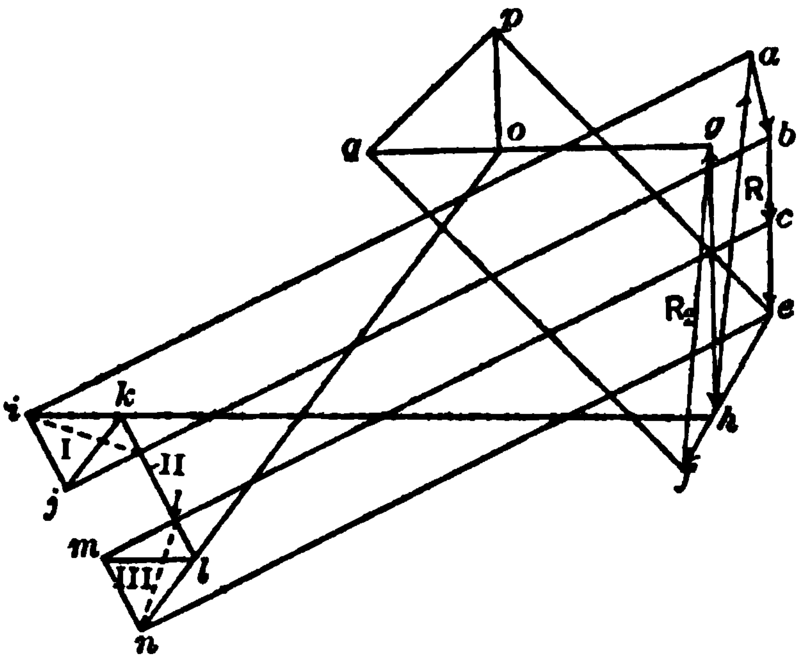

Fig. 38C. Unsymmetrical Truss. Stress-diagram

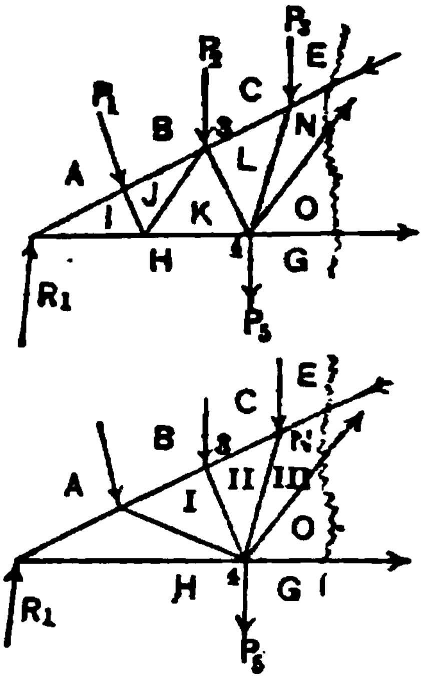

Fig. 38D. Unsymmetrical Tru Truss-diagrams

The frame may be of any form as long as it is rigid so the bracing may be chang as shown in Fig. 38D and the stress-diagram proceeded with as in Fig. 3 until the stresses in *EN*, *NO* and *OG* have been found. This will locate t point *O*. Returning to Fig. 38B, it is found that at joint 4 all the stresses b *KL* and *LO* are known; hence these can be found in the usual manner. Join is next considered and so on until the diagram is complete. The line *qf* in F 38C will pass through *f* if the work is correct. Although the method for det mining the CHARACTER OF THE STRESSES has been explained, it will be repeat here in a more general manner. Take, for example, joint 8, in Fig. 38B, wh is in equilibrium under the action of the stresses *go*, *op*, *pq* and *qg*, as indicated in Fig. 38E. The stress-diagram for this joint is shown in Fig. 38F, separated from Fig. 38C. It is assumed that the stress in *GO* is tension. Then in Fig. 38F, starting at *g* we l off *go*, *op*, *pq* and *qg*, placing the arrow-heads as shown. Transferring th arrow-heads to the ends of the cut pieces in Fig. 38E indicates at once t KIND OF STRESS. The following examples illustrate the above methods.

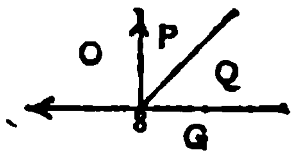

Fig. 38E. Unsymmetrical Truss. Forces at Joint 8

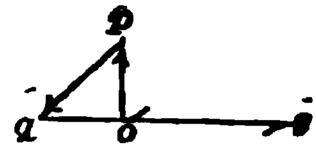

Fig. 38F. Unsymmetri Truss. Stress-polygo

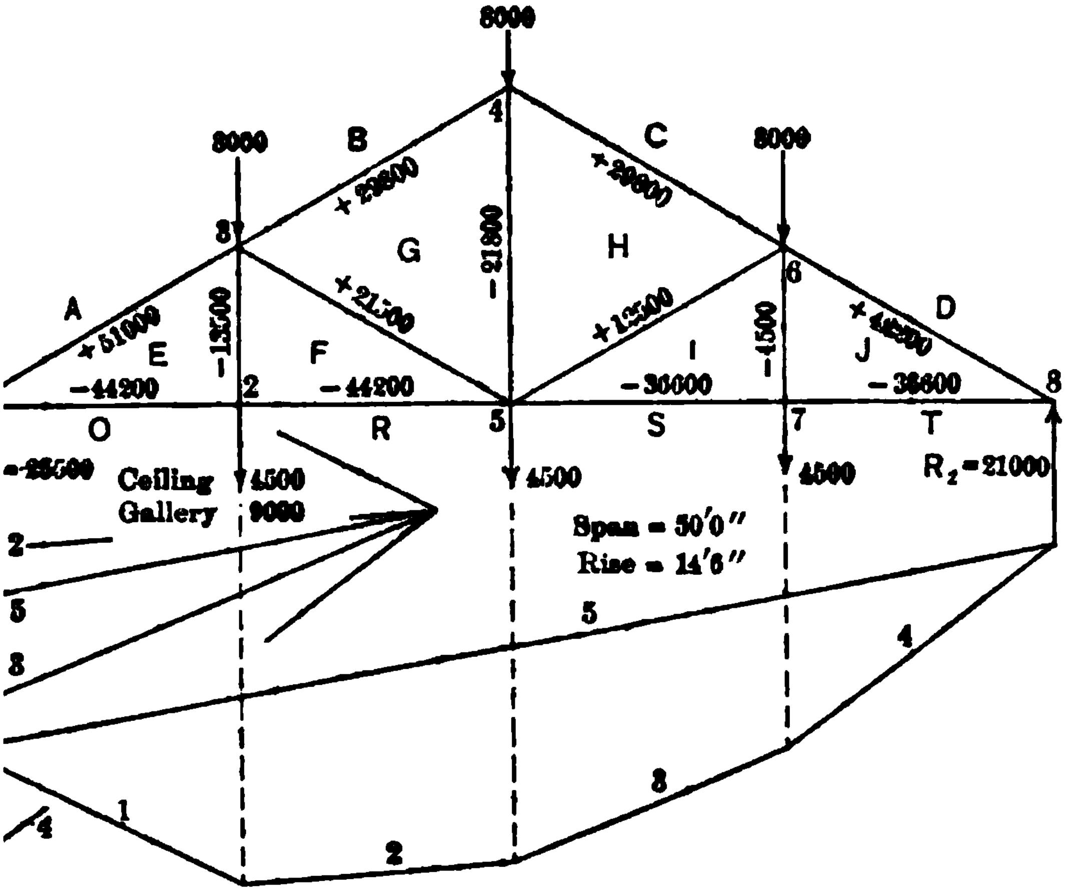
Unsymmetrically-loaded Truss. Example 24. Fig. 39 represents the d gram of a truss similar to that shown in Fig. 1, but of a greater span and hav a gallery supported from it at one side only. The approximate roof and ceili loads are indicated by the figures near the arrows, and the weight coming one truss from the gallery would be about 9 000 lb. The first step tow drawing the stress-diagram is to determine the reactions at the two ends of t

will give the supporting forces. This is readily done in this example
OD OF MOMENTS explained on pages 322 to 324. Moments are first
joint 1. As the loads at joints 2 and 3 have the same arm, they
gether before multiplying by the arm. The loads at joints 4 and 5



39. King-rod Truss. Truss-diagram and Equilibrium-polygon

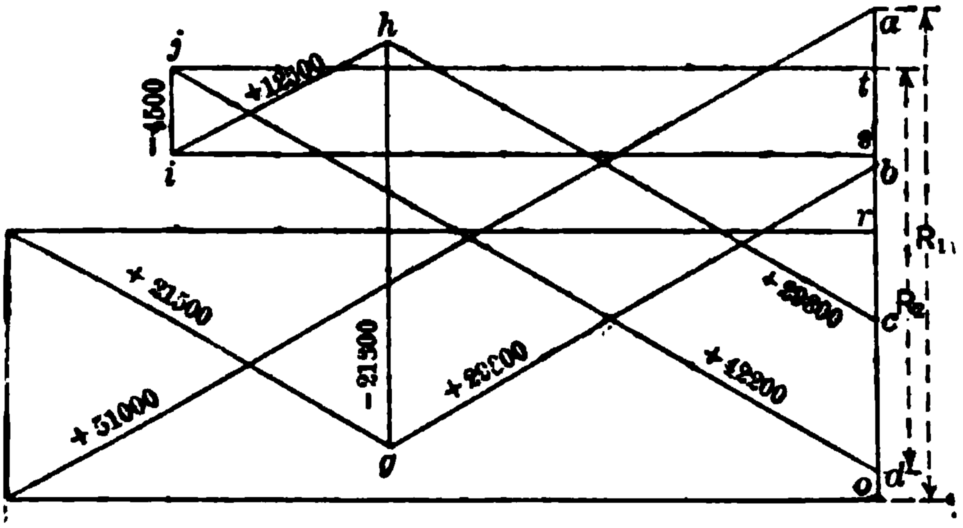


Fig. 39A. King-rod Truss. Stress-diagram

5 and 7 are treated the same way. The moments about joint 1 will

oo + 4 500 + 9 000)	= 21 500] lb × 12½ ft =	268 750 ft-lb
oo + 4 500)	= 12 500] lb × 25 ft =	312 500 ft-lb
oo + 4 500)	= 12 500] lb × 37½ ft =	468 750 ft-lb
The sum of the moments	=	1 050 000 ft-lb

iese CLOCKWISE MOMENTS about joint 1 must be balanced by the
WISE MOMENT of R_2, the LEVER-ARM of which, with reference to
ft. Knowing the arm, 50 ft, the force R_2 is obtained by dividing
e moments of the loads by the span. Dividing 1 050 000 ft-lb by

50 ft, the result is 21 000 lb, which is the reaction or supporting force at joint and R_1 must equal the difference between the sum of the loads and R_2. Th sum of the loads is 46 500 lb and subtracting from this 21 000 lb, the remainde 25 500 lb, is the value of R_1. The stress-diagram (Fig. 39A) may now be draw First draw a vertical line *oa* equal to R_1, 25 500 lb. From *a* and *o* draw lin parallel respectively to *AE* and *EO*, locating the point *e*. For the stress-lin at joint 2 measure up from *o* a distance equal to the load at that joint, 13 500 l which gives the point *r*, and from *e* and *r* draw lines parallel to *EF* and *F* which intersect at *f*. At joint 3, the sides of the stress-polygon are *fe*, *ea*, *bg* and *gf*. Draw the stress-polygons for joints 4, 5, and 6 in the order in whic

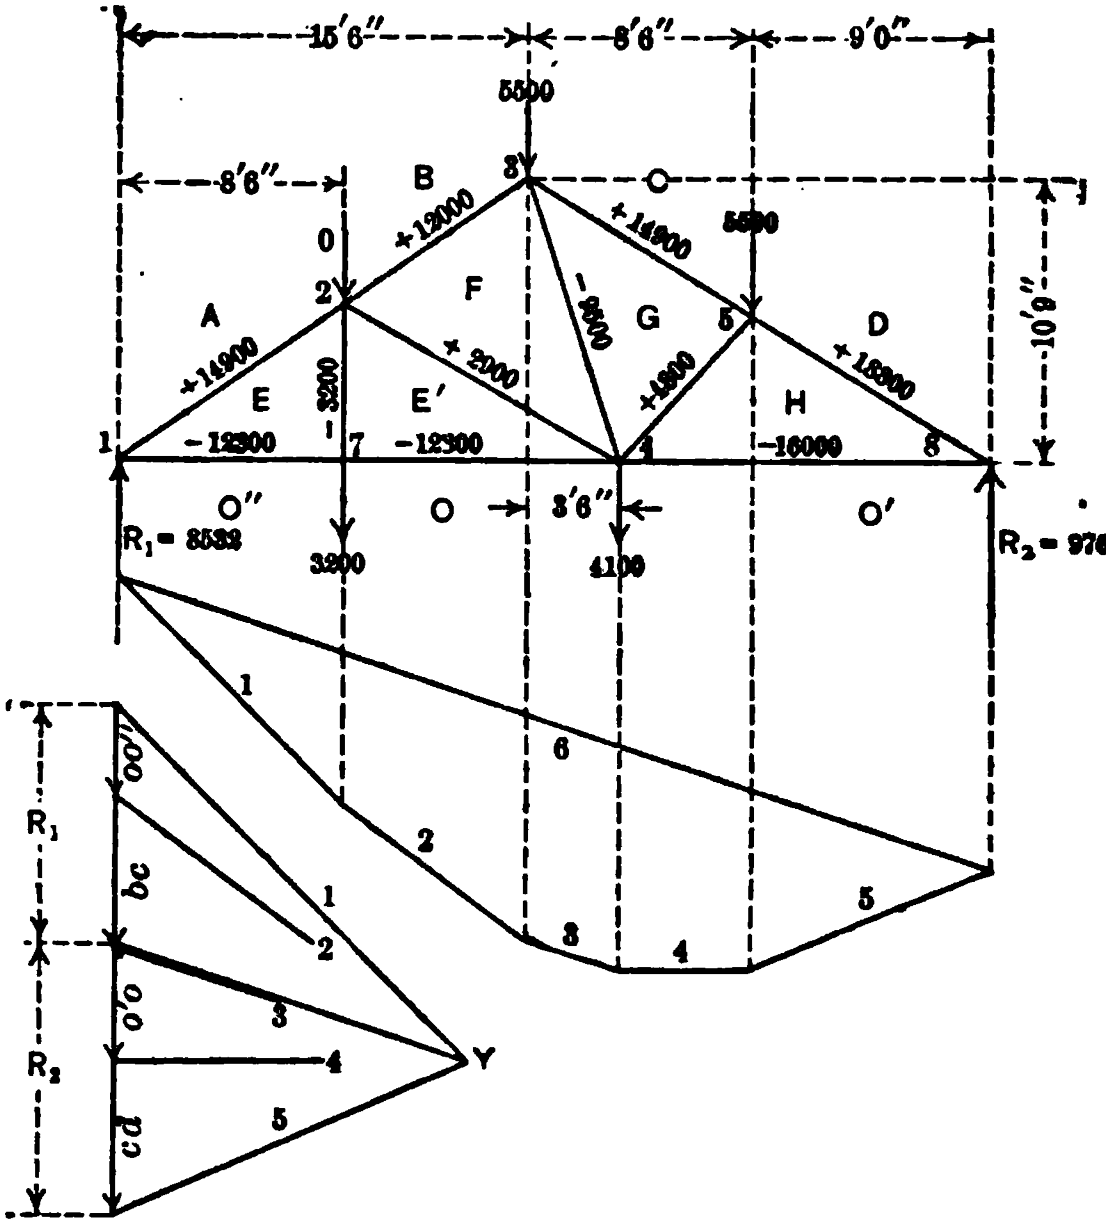

Fig. 40. Unsymmetrical Truss. Truss-diagram and Equilibrium-polygon

they are numbered. At joint 6 the sides of the stress-polygon are *ik*, *kc*, *cd*, and *ji*. If the diagram has been correctly drawn, the line *ij* will be just equ to the load at joint 7. The sides of the stress-polygon for joint 7 are *ts* equal t 4 500 lb, *si*, *ij* and *jt*, the only line to be drawn being *jt*, which must be paral to *JT*. Consequently *j* must be exactly opposite *t*, or the polygon will not clos The distance *dt* should be equal to R_2.

Unsymmetrically-loaded Truss. Example 25. Fig. 40 is the diagram c a wooden roof-truss. The actual loads were about as given on the diagram There were purlins at joints 3 and 5 only, and the ceiling below was suspende by rods from joints 4 and 7, joint 4 being fixed by the framing of the ceilin The moments of the loads about joint 1 are:

3 200 lb × 8½ ft = 27 200 ft-lb
5 500 lb × 15½ ft = 85 250 ft-lb
4 100 lb × 19 ft = 77 900 ft-lb
5 500 lb × 24 ft = 132 000 ft-lb

Sum of moments = 322 350 ft-lb

: sum of the moments by the distance between the supporting forces, s 9 768 lb as the value of R_2. : the loads is 18 500 lb. Sub- 768 lb, 8 532 remains as the . To draw the stress-diagram, $o''a$ equal to 8 532 lb equal raw ae and eo''. The sides of olygon for joint 2 are ea, ab, bf, At joint 3, fb is known and red down and made equal to ; and gf are then drawn. At t by measuring upwards from locating point o' and draw gh t joint 5, hg and gc are now uals 5 500 lb and a line from d allel to DH. This should pass through h, completing the diagram. rod 2–7 is the load at joint 7.

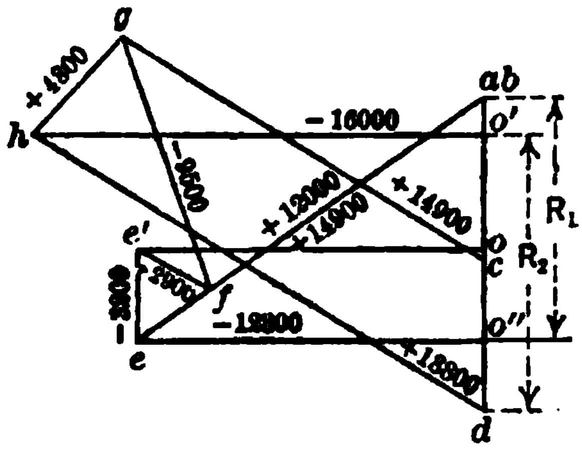

Fig. 40A. Unsymmetrical Truss. Stress-diagram

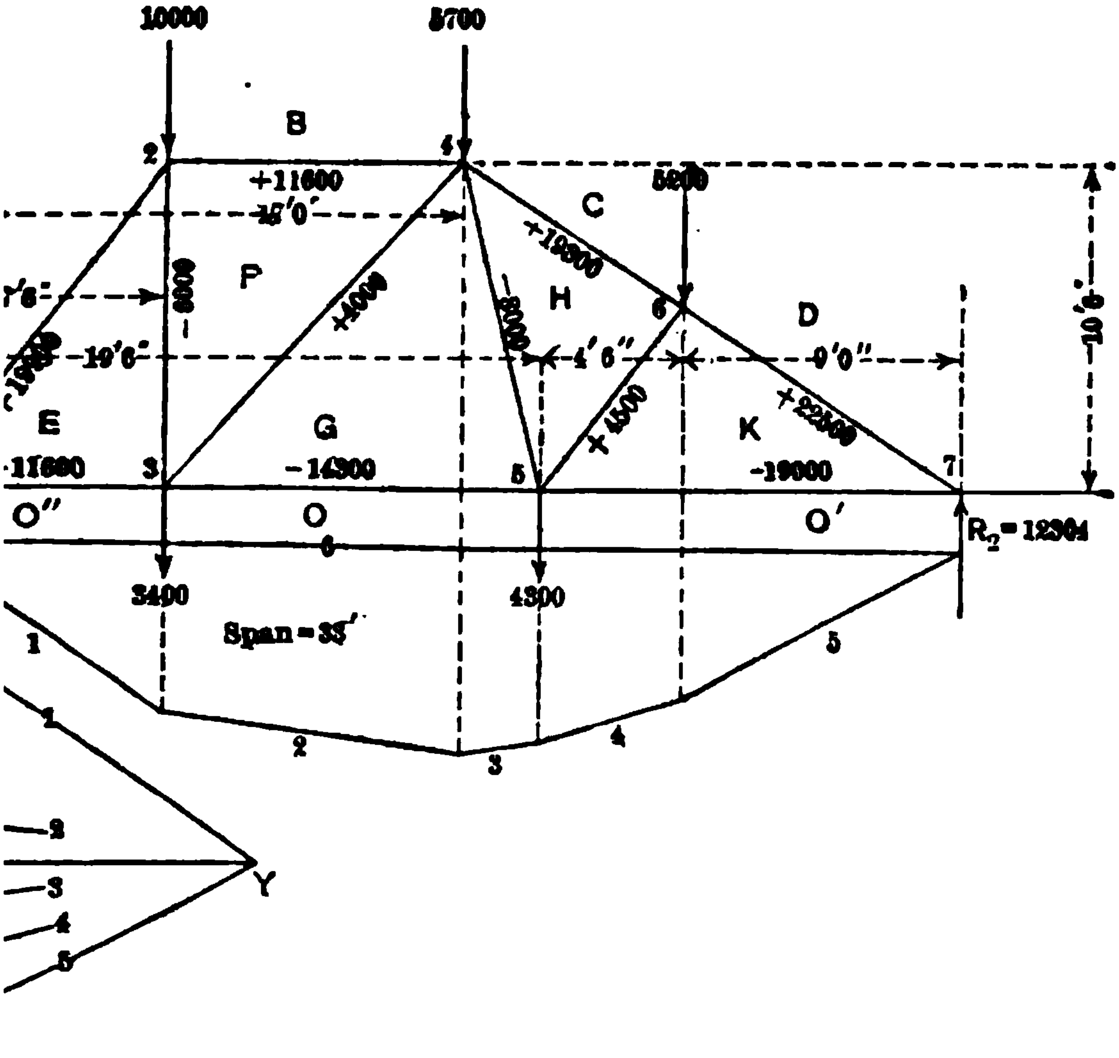

. Unsymmetrical Truss. Truss-diagram and Equilibrium-polygon

rically-loaded Truss. **Example 26.** Fig. 41 is the truss-diagram ss in the same building in which the truss shown in Fig. 40 was moments about joint 1, there results, for the sum of the moments,

[illegible] and dividing this by [illegible] it gives [illegible] as the value of R_2. T[illegible] sum of the loads [illegible] which [illegible] is the value of R_1. T[illegible] stress-diagram Fig. 41A is drawn in the same manner as in Fig. 40. Starti[illegible] with [illegible] equal to R_1, [illegible] is drawn equal to the load at joint [illegible], and the act[illegible] stress in [illegible] is found by [illegible] the length of the line [illegible]. If the stress-diagram correctly drawn a line through [illegible] parallel to KD will pass through the point previously determined. The CHARACTER OF THE STRESSES is indicated by t[illegible]

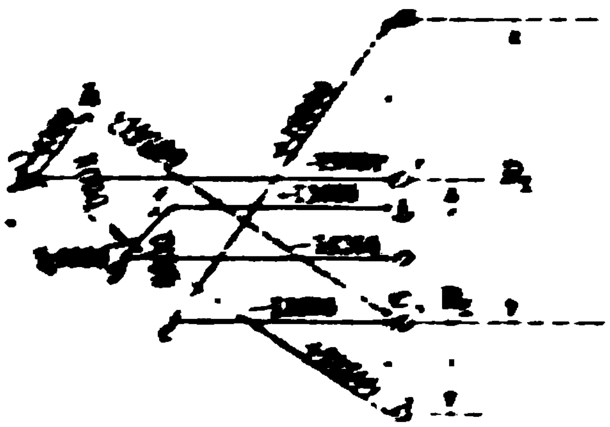

Fig. 41A. Unsymmetrical Truss. Stress-diagram

PLUS AND MINUS SIGNS in Fig. 41, p[illegible] denoting compression. If the stress-d[illegible] grams in the last three examples a[illegible] compared with those for symmetrica[illegible] loaded trusses of similar shape it is fou[illegible] that while the stress-diagrams, Figs. 3[illegible] 40A and 41A are unsymmetrical, th[illegible] are of the same general character, a[illegible] the stresses are all of the same kind when the supporting forces are equ[illegible] This condition holds true for most tri[illegible] gular trusses, but for trusses with ho[illegible] zontal or curved chords, unsymmetri[illegible] loading usually causes a REVERSAL OF THE STRESS IN KIND in one or more of t[illegible] diagonals or verticals; and if the truss contains any four-sided panels, an ad[illegible] tional diagonal is generally required. This is particularly true of the Ho[illegible] TRUSS; and as this truss is very extensively used by architects and builders, will now be considered at some length with special reference to the effect UNSYMMETRICAL LOADING.

Howe Trusses, Unsymmetrically Loaded. When a HOWE TRUSS is load[illegible] symmetrically on each side of the middle, all of the braces incline downwa[illegible] from the center, as in Figs. 14 to 17, Chapter XXVI; and if there is an e[illegible] NUMBER OF PANELS, the middle panel needs no brace. When a load of mu[illegible] magnitude is placed on one side of a truss having an ODD NUMBER OF PANE[illegible] without a corresponding load on the other side, a brace is always required the middle panel and the brace should incline downward from the side which is most heavily loaded.

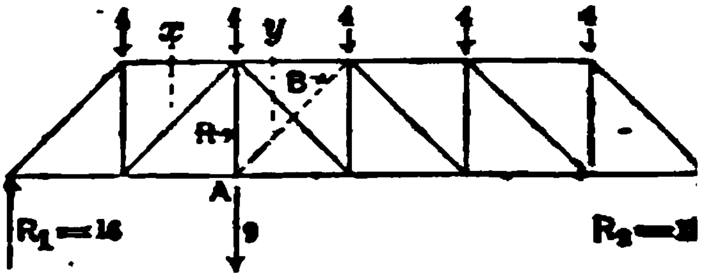

Fig. 42. Howe Truss. Truss-diagram

Howe Truss with Even Number of Panels. When the truss has an EVEN NUMBER OF PANELS, an unsymmetrical load causes a greater stress in the braces on one side of the truss than on the other; and if there is a sufficient difference in the loads on the two sides of the truss, it causes compressive stres[illegible] in one or more of the rods and tensile stresses in one or more of the braces. [illegible] this truss is especially designed with the idea of having the BRACES IN CO[illegible] PRESSION and the VERTICALS IN TENSION, whenever the loading causes tensi[illegible] in a brace, or compression in a rod, the direction of the brace should be revers[illegible] causing it to be in compression again. Consider, for example, the truss sho[illegible] in Fig. 42, divided into 6 panels of equal width and loaded with 4 tons at ea[illegible] of the upper joints and 9 tons at the second lower joint from the left. Wi[illegible] out the bottom load of 9 tons, the brace in the third panel should incline do[illegible] ward from the middle joint, as shown by dotted line at B; but when the load 9 tons is added, it causes a tensile stress in B and a compressive stress in R.

he DIRECTION OF THE BRACE IS REVERSED, as shown by the full line: compression and the vertical R has no stress except that caused by ad of 9 tons. There are the same results when the load of 9 tons the joint directly above, instead of at the lower joint, although in e is no stress at all in R except that due to the weight of the tie-beam. ad of 9 tons is reduced to 6 tons, no brace is required in the third when the bottom load i tons, a brace in the tion is required, as 43. (See page 1006.)

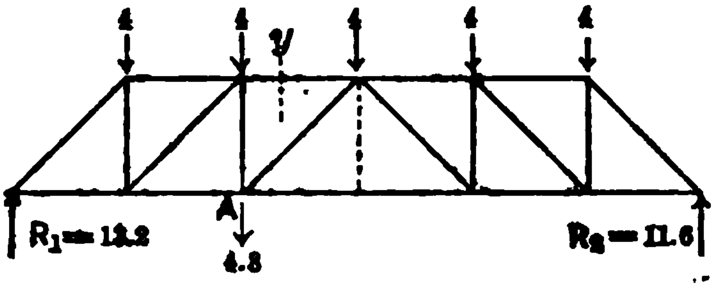

Fig. 43. Howe Truss. Truss-diagram

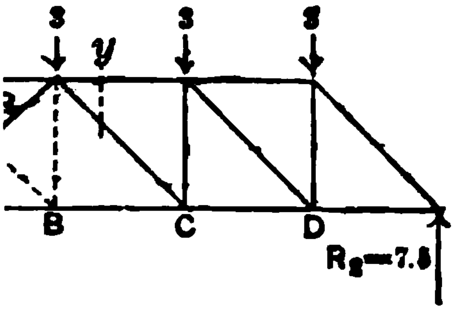
russ with Uneven Panels. In the five-shown in Fig. 44, a tons at A requires nent of braces shown lines, and when the load at A is increased to more than 15 tons, needs to be reversed, as shown by the dotted line. The stress-ys shows in which direction any brace should be placed to be in but this may be determined also by the following rule. When the ads to the left of any section, taken between R_1 and the middle, is the reaction R_1, the direction of the brace cut by that section must rom its normal direction. When the sum of the loads is less than should be in its normal position. When the sum of the loads, to e section, is just equal to R_1, no brace is required. For example, consider a section at x, Fig. 44. Here the sum of the loads to the left is 10.5 tons, which sum is less than R_1; hence the brace should be in its normal direction. If the section is at y, the sum of the loads to the left is 13.5 tons, which sum is greater than R_1; hence a brace is required, slanting downward from the more heavily loaded side. When the sec-



we Truss. Truss-diagram

Fig. 42, the load to the left is 4 tons, an amount less than R_1; ce in that panel should be in its normal position. When the sec-he sum of the loads is greater than R_1; hence the brace in that reversed. When the section is at y, Fig. 43, the sum of the ft is less than R_1; hence the brace should be in its normal posi-s rule the proper direction of the brace in any panel is indicated, he complication of the loading and of the width of the panels; but he rule, it is first necessary to determine the supporting forces, found either by the METHOD OF MOMENTS, as explained in r by the GRAPHICAL METHOD.

rical Howe Truss. Example 27. As an example of an unsym-E TRUSS unsymmetrically loaded, the truss represented in Fig. 45 This truss is supposed to support a flat roof and a wooden tower rn. The position of the tower necessitates a division of the panels o that the truss is quite unsymmetrical. It is assumed that the oof, snow, and tower constitute the loads in pounds at the upper d by the figures. The graphical determination of the reactions clearly shown in Figs. 45 and 45A. The only panels of this truss is any question as to the direction of the braces are the third and

fourth. Taking a section at x, the sum of the loads to the left is greater th R_1; hence the brace should be placed as drawn. A section taken through makes the sum of the loads to the left less than R_1; and hence the brace shou be in its normal position. The stress-diagram of this truss is readily draw starting with wa equal to R_1, and going from joint to joint as in previous exa ples. The completed stress-diagram is shown in Fig. 45A.

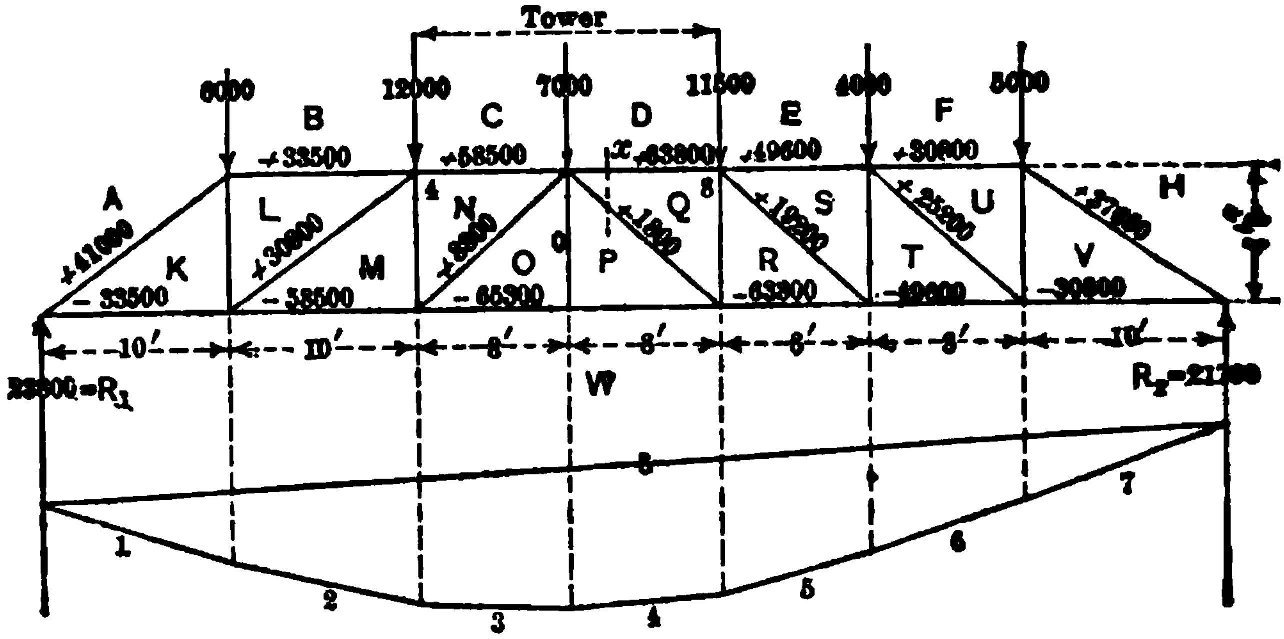


Fig. 45. Howe Truss. Truss-diagram

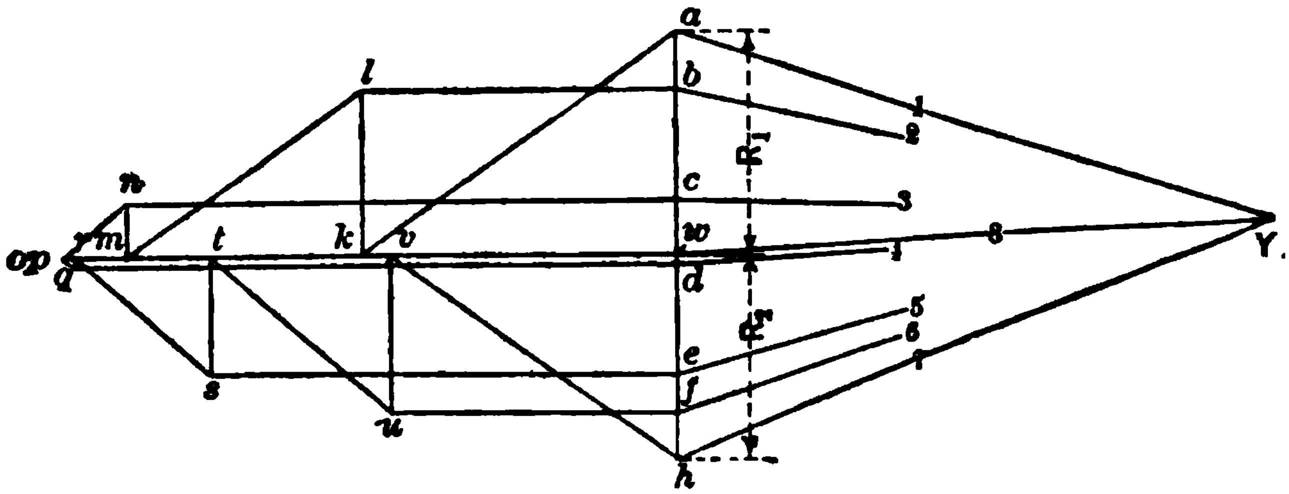

Fig. 45A. Howe Truss. Stress-diagram

Counterbraces. These are EXTRA BRACES that are put in a truss whe stresses are REVERSED IN CHARACTER by a load which may be applied for a tim and then removed. For illustration, consider the truss represented in Figs. 4 and 43. Here it has already been shown that when the load at A is less than 6 the brace in the third panel should be in the position shown in Fig. 43; whil when the load is greater than 6, the brace should be in the position shown b the full line, Fig. 42. Now, if the load at A represents the weight of a crowde gallery or a hoist raising a heavy load, or in fact if it represents any live load it is evident that when this live load is absent the brace in the third panel shoul be in its normal position; and that when this maximum load is present a brac is needed in the opposite direction. As it is not practicable to move the brac to suit the changing conditions of the loading, it is necessary to put in tw braces, only one of which, however, is in action at a time. The stress in a HOWE TRUSS, therefore, which is subject to a variable and unsymmetrical loading, should be computed for at least TWO CONDITIONS OF LOADING: first for the condition resulting from the APPLICATION OF THE MAXIMUM LOAD: an

or the condition resulting from the REMOVAL OF THE VARIABLE LOAD. should be designed to resist both conditions. SNOW is a VARIABLE hich such trusses are often subjected; but as it is nearly uniformly over the roof, it does not change the CHARACTER OF THE STRESSES he members. If a truss, therefore, is designed for a MAXIMUM SNOW- more than strong enough when there is no snow. Moreover, the strength of the chords is usually sufficient to resist any slight inequality ling. The principal VARIABLE VERTICAL LOADS, therefore, to which s may be subjected and which require counterbraces, are those due ht of people, merchandise, etc., these loads being either suspended uss by rods or brought upon the truss by a floor supported by the rd. The truss shown in Fig. 45, also, is an instance of such loading. s given by the figures indicate merely the combined dead loads and During a high WIND the weight on the LEEWARD SIDE of the tower reased and on the WINDWARD SIDE decreased, so that when the wind the right, the load at 4 is greater and at 8 less than indicated; while ind blows from the left the load is increased at 8 and decreased at 4. es COUNTERBRACES in both the third and fourth panels. As counter- o harm, even if never brought into action, it is always well to use middle panels wherever the loads are at all variable.

er Trusses. These trusses may be considered as UNSYMMETRICALLY SSES, for although the loads may be symmetrical in relation to the ure usually unsymmetrical in relation to the supports. The method G THE SUPPORTING FORCES and drawing the stress-diagrams is shown wing examples:

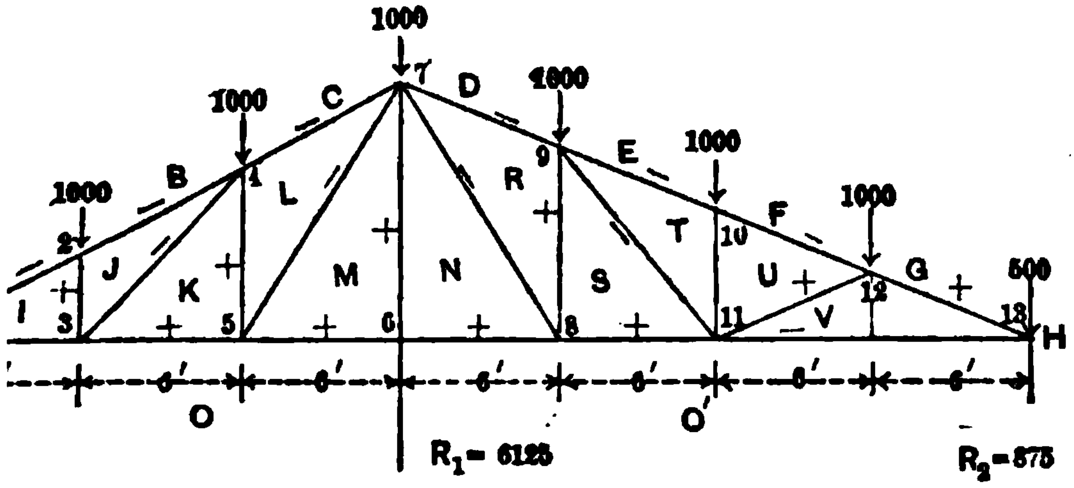

Fig. 46. Cantilever Truss. Truss-diagram

r Truss. Example 28. Fig. 46 is the diagram of a CANTILEVER s might be used to support the roof over a grand stand or railway- orm and may be constructed either of wood or steel, steel being The first step towards determining the stresses is to find the sup- s. For this purpose the panel-loads have been made 1 000 lb each, ng of equal width. These assumed loads simplify the problem and as the actual loads to explain the method of procedure. In CANTI- ES the loads at the ends of the trusses, as well as the intermediate be taken into account. These end-loads are each equal to one-half loads. To find the supporting forces moments are taken about e sum of the moments of the external vertical forces is 147 000 ft-lb. its must be resisted by the moment of the force R_1, which acts in rection with reference to the same point and with a lever-arm of ing 147 000 ft-lb by 24 ft, there results 6 125 lb as the value of

and as the total load is 7 000 lb, R_2 must be 875 lb. The stress-diagram may be commenced either with the forces at joint 1 or with those at joint 13; but as the external loads were laid off from left to right in the preceding examples, the same order is used here. Commencing then with joint 1, lay off on a vertical line the load *oa* equal to 500 lb, which acts down, and draw *ai* and *io* parallel respectively to *AI* and *IO*. The forces act from *o* to *a*, from *a* to *i* (from the joint) and from *i* to *o* (toward the joint), showing that *AI* is in tension and *IO* in compression, a REVERSAL OF THE CHARACTER OF THE STRESSES developed in the corresponding members of a truss supported at both ends. Next, at joint 2, the stress *ia* is now known, and *ab* equal to 1 000 lb is laid off; then *bj* and *ji* are drawn, *BJ* being in tension and *JI* in compression. The forces at joint 3 are next drawn and then those for the remaining joints, in the order in which they are numbered. At joint 6, the first force known is the supporting force R_1, represented by *o'o* laid off equal to 6 125 lb and acting upward. The sides of the polygon of forces for joint 6 are *o'o*, *om*, *mn* and *no'*. The stress in *MN* is equal to the supporting force *o'o*, which is evident from the truss-diagram. In practice, R_1 would probably be a COLUMN continued to the apex of the truss. At joint 12 the stresses already determined are *vu*, *uf*, and *fg* equal to 1 000 lb. *gv* must close the polygon. It will be noticed that *gv* acts toward joint 12; hence the rafter in the end-panel is in compression. If a line drawn from *g* parallel to the rafter, passes through *v*, the stress-diagram is correct; if it does not pass through *v*, then either the stress-diagram has not been drawn with

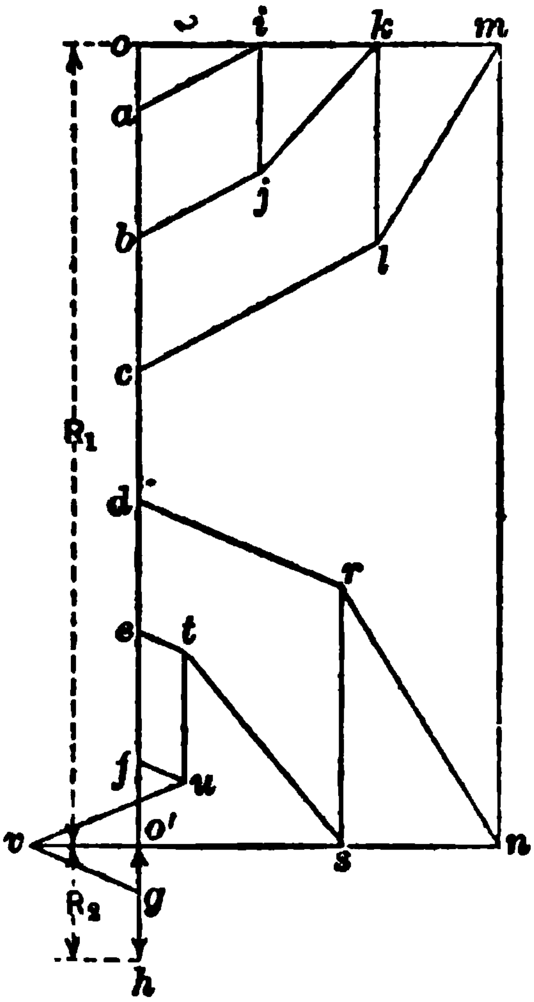

Fig. 46A. Cantilever Truss. Stress-diagram

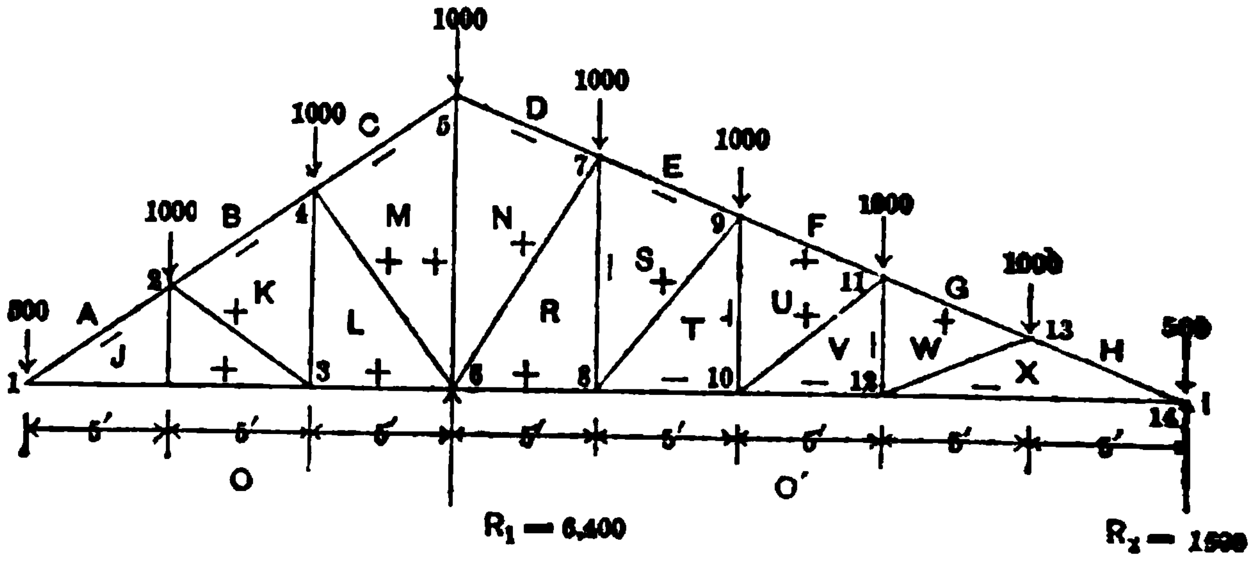

Fig. 47. Cantilever Truss. Truss-diagram

sufficient accuracy or an error has been made in computing the supporting forces. In drawing the stress-diagram for CANTILEVER TRUSSES, it is important to keep in mind THE DIRECTION IN WHICH THE FORCES ACT, in order to determine which members are in compression and which in tension.

r Truss. Example 29. Fig. 47 is the diagram of a truss similar that shown in Fig. 46, but with the DIAGONAL BRACES INCLINED SITE DIRECTION, so as to cause them to be in compression and the tension. The supporting forces are found by the same methods mple 28, and the m, also, is drawn by used for Fig. 46A. however, the stress l post MN is con- than the reaction a large portion of ransmitted to joint uts LM and NR. three sections of the right side are on and three sec- bottom chord are This is because in projection of the proportion to the less than it is in n the stress-lines t of the load-line he STRESSES ARE KIND. This truss pted to wooden vith vertical rods truss shown in

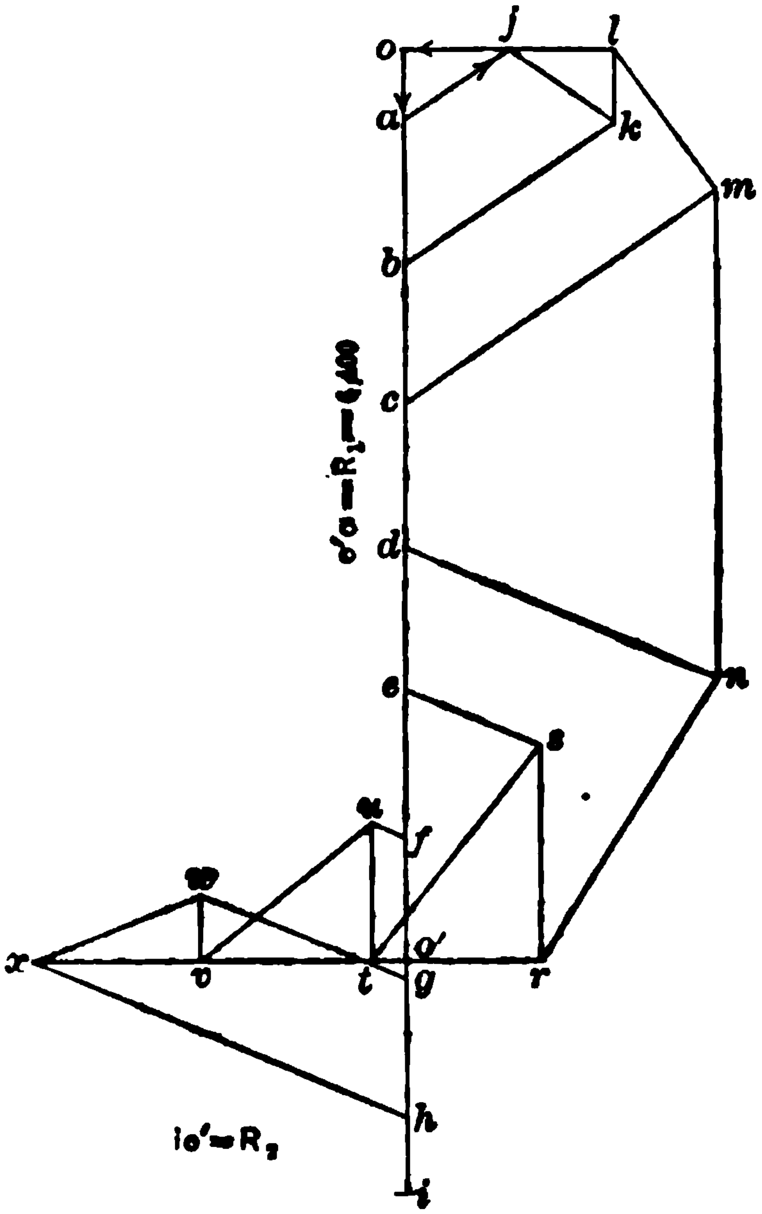

Fig. 47A. Cantilever Truss. Stress-diagram

antilever Truss. In this example, wn a truss with at the outer end , so that R_1 acts determine the character of the supporting forces moments are taken about rs:

nts of loads to the right of joint 7, the figures on the force-arrows gram indicating thousands of pounds:

$$8) + (5 \times 16) + (5 \times 24) + (12.5 \times 32) = 640\,000 \text{ ft-lb}$$

nts of loads to the left of joint 7:

$$(2.5 \times 24) + (5 \times 16) + (5 \times 8) = 180\,000 \text{ ft-lb}$$

its act in opposite direction with reference to the center o. 6, the smaller sum, is subtracted from the larger, leaving an ment of 640 000 ft-lb − 180 000 ft-lb = 460 000 ft-lb, tending down on the right of R_2 at joint 6 and to lift it up on the left. st be resisted by the moment of the reaction R_1, which has an viding 460 000 ft-lb by 24 ft, 19 250 lb results as the reaction equires a downward force of this magnitude to maintain the um. As the support at 6 must resist this downward pull as R_2 will equal the sum of the loads plus the pull R_1, or 45 000 lb

+ 19 250 lb = 64 250 lb. Having obtained the value of the supporting forc the stress-diagram is drawn by laying off on a vertical line *oa* downward, equ

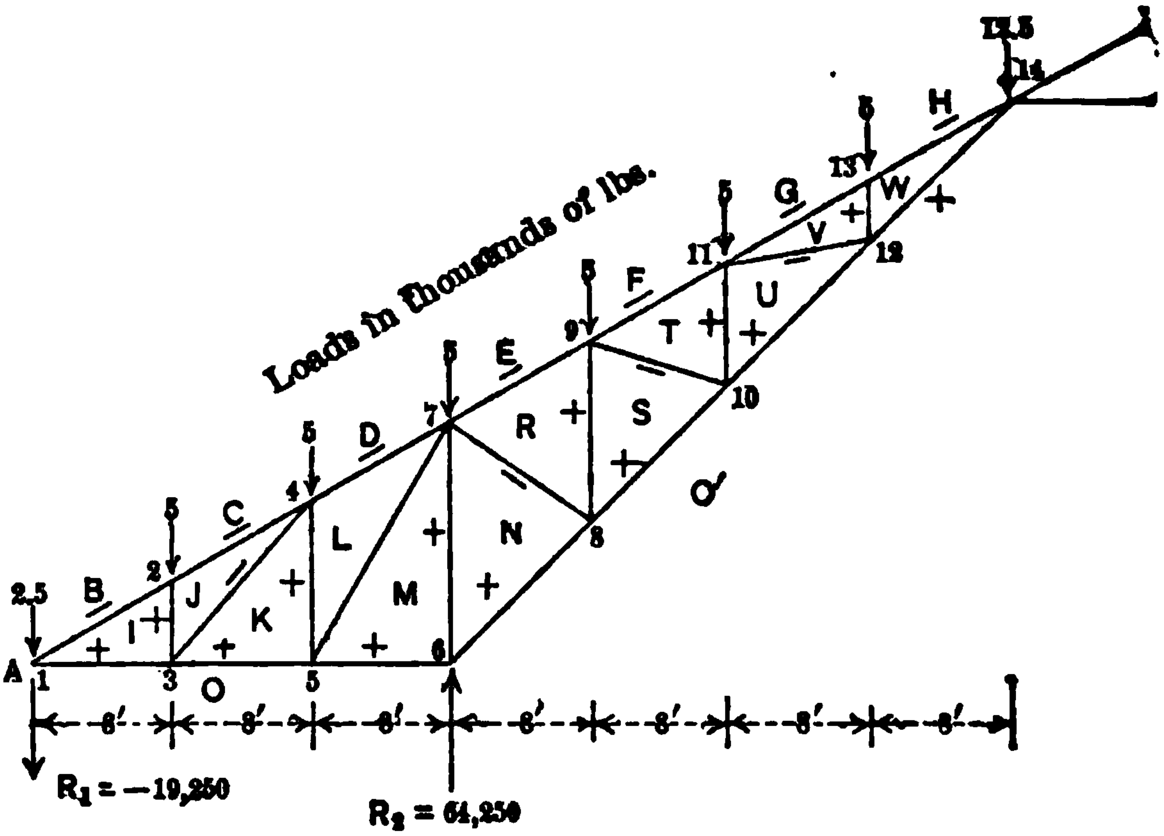

Fig. 48. Cantilever Truss. Truss-diagram

to 19 250 lb equal to R_1. The next force is the load of 2 500 lb, which also a down, and which locates the point *b*. From *b* a line parallel to *BI* is drawn a from *o* a line parallel to *I* locating the point *i*. *bi* a from joint 1 and *io* towa it, showing that *BI* is tension and *IO* in compressi The remainder of the stre diagram is drawn by the sa methods employed for diagrams of Figs. 46A a 47A. At joint 6 the for polygon is begun with force R_2 or *o′o*, which a upward, and the upper e of which must be at *o*. Co sequently *o′* is located measuring downward from 64 250 lb. The sides of stress-polygon for this jo are *o′o*, *om*, *mn* and After *gh*, the load at joint is laid off, the remaining d tance *ho′* should be just eq to the load at joint 14, 12 500 lb. If R_1 and R_2 ha been correctly computed and the stress-diagram accurately drawn, the poi *s*, *u* and *w* will fall in the line *no′*.

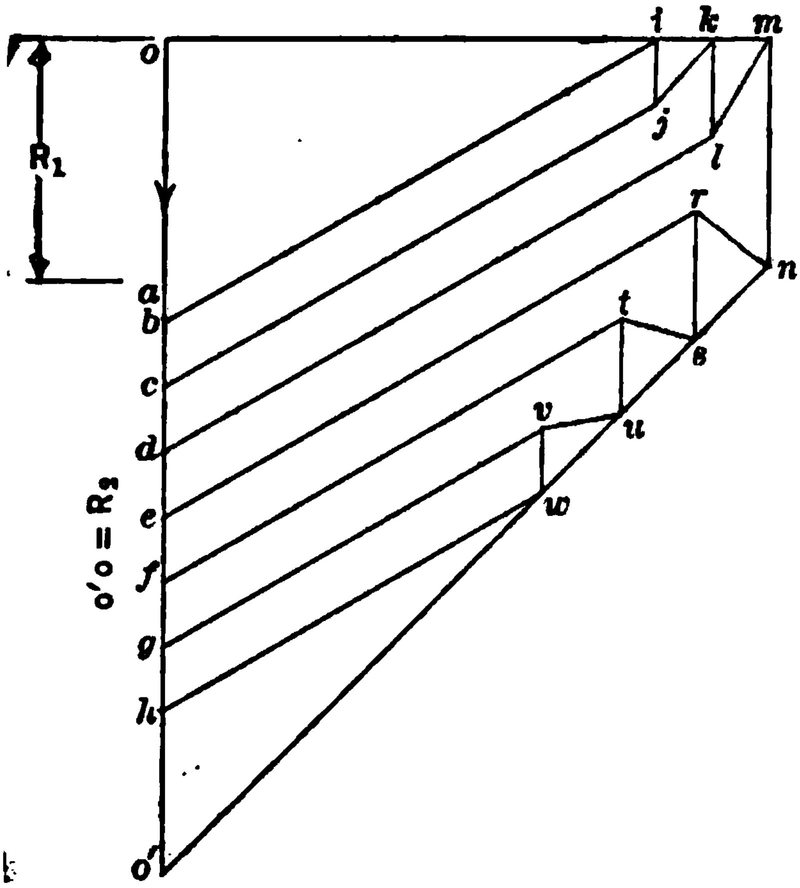

Fig. 48A. Cantilever Truss. Stress-diagram

6. Determination of Wind-Load Stresses

ads. Thus far the stresses due to VERTICAL LOADS only have been :he pressure of the WIND being combined with the DEAD LOAD and ıs acting vertically. For TRIANGULAR and FINK TRUSSES this ıfficiently accurate, as the wind-pressure never causes a maximum ss of that obtained by the method explained in connection with the ımples. For TRUSSES WITH CURVED CHORDS and in fact for almost STEEL TRUSSES except those of the FINK and FAN TYPES, it is not der wind-pressure as acting vertically, because the wind acts gen- rection at right-angles to the roof-surface, and upon but one side of given time, thus loading the truss unsymmetrically and often caus- of an opposite kind from those produced by a vertical loading. ı are inactive under a vertical load may therefore be necessary to ce of the wind, or the total stress due to wind and vertical load y be greater than it would be if the wind-pressure were considered load. To design a roof-truss correctly, therefore, it is necessary the stresses due to VERTICAL LOADS and WIND-LOADS separately bine them so as to get the GREATEST STRESS that may be produced obable conditions. (See statement on page 1049.)

ıords. In the calculation of trusses with CURVED CHORDS it is ctice to find the stresses for the following different loadings and them to obtain the maximum stress: Stresses due to the wind on e truss nearer the expansion-end; stresses due to the wind on the ss nearer the fixed end; stresses due to the permanent dead loads; snow covering the entire roof or only one-half of the roof; and, in stresses due to snow covering only a small area of the roof on one

Snow. It is generally assumed that the maximum wind-pressure load can not act on the same half of the truss at the same time. h straight rafters it will generally be sufficient to find the stresses nanent dead load, and to the wind from both directions, disregard- ad when the pitch of the roof is 45° or greater. For the Northern ıe pitch is less than 30°, it is well to consider that a heavy sleet h sides of the roof at the time of a heavy wind and to add about f roof-surface to the dead load to allow for it. In localities where s may be expected, the stresses due to the full snow-load should as these combined with the permanent dead load may exceed ad load, sleet and wind-pressure.

-Diagrams. These are affected by the manner in which the truss If both ends of the truss are fixed, the WIND-REACTIONS are paral- ant wind-load; if one end is free to move horizontally, that is, supported on a ROCKER, the reaction at the roller-end is vertical fixed end inclined. "If one end be fixed and the other merely a smooth IRON PLATE, the reaction at the free end may have a onent equal to the vertical component multiplied by the COEFFI- ON, which is about one-third."

'ree Ends of Trusses. Wooden trusses may be considered as ds. STEEL TRUSSES, when supported on masonry walls, should XED and the other FREE to move; and when the span exceeds d should be supported on ROLLERS to permit of expansion or hen steel trusses are supported by steel columns, as in steel mill- usses are RIGIDLY ATTACHED to the columns and no provision

is made for expansion. In such buildings the wind-pressure causes a BENDI STRESS in the columns, which must be provided for.

Truss with Fixed Ends. Example 31. Wind-pressure is usually assum to be applied uniformly over one side of the roof and to act at right-angle the surface of the roof. The joint-loads or panel-loads, therefore, are proportio to the roof-areas supported. When the joints divide the rafter into panels of eq length, the joint-loads are uniform, except for the joints at the edges of the r The actual wind-pressure is obtained by multiplying the roof-surface by values given in Table IX, page 1053. For this example the triangular truss sho in outline by Fig. 49 is considered and it is assumed that the span and spac of the truss are such as will give a load of 1 000 lb at joints 2 and 4. The lo at joints 1 and 5 are only one-half of those at 2 or 4. To find the support forces or reactions, draw a line representing the resultant of the loads, cutt the bottom chord at X. As the loads are symmetrical the resultant acts at middle of the rafter and at right-angles to it. The reactions R_1 and R_2 inversely proportional to the two segments into which a horizontal line join the points of support is divided by the resultant, or in this case to X–7 and 1-

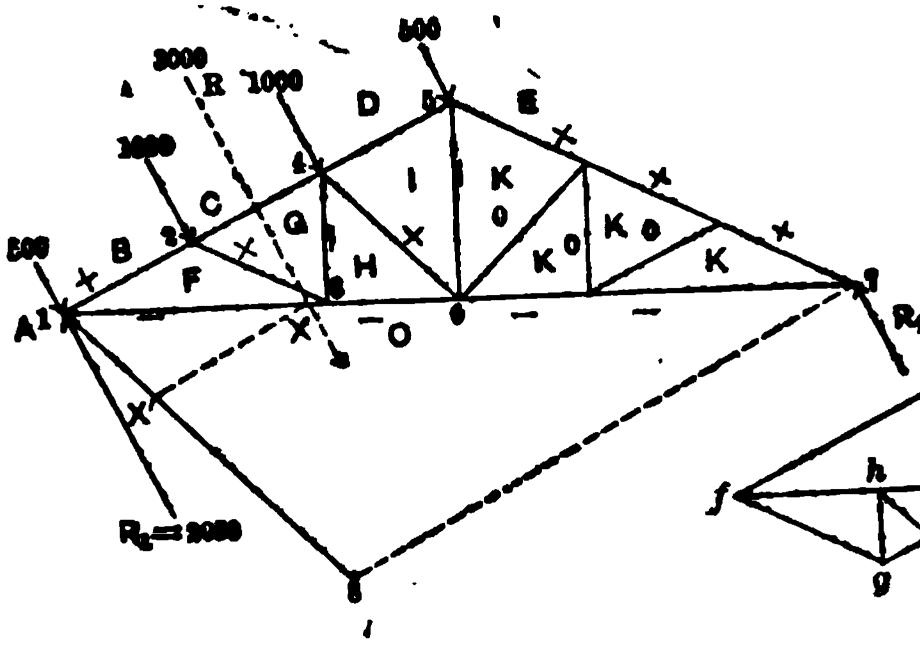

Fig. 49. Triangular Truss. Truss-diagram

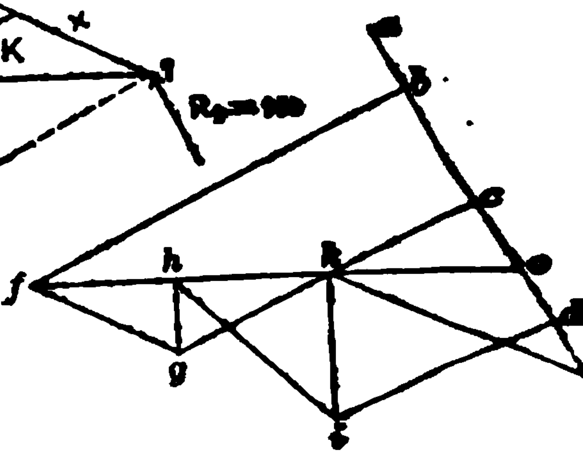

Fig. 49A. Triangular Trus Stress-diagram

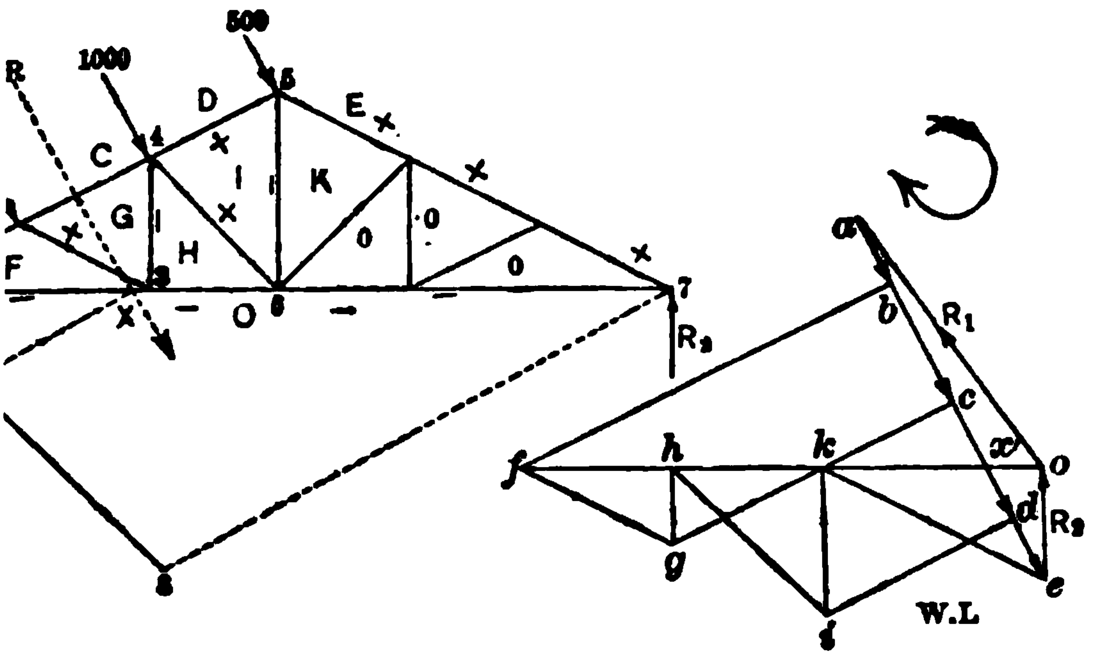
the greater reaction being at joint 1. The sum of the reactions are equal to sum of the loads. To find the reactions graphically, draw a line from joint at any angle, say from 30° to 45°, and measure off a distance equal to the t load. In Fig. 49 the line 1–8 represents 3 000 lb. Join 7 and 8, and from draw a line parallel to 7–8, intersecting 1–8 at X'. Then 8–X' is the reactio joint 1 and X'–1 the reaction at joint 7. To draw the stress-diagram, Fig. 4 first draw the load-line *ae* equal to the sum of the loads, in this case 3 000 lb, perpendicular to the rafter 1–5, and divide it so that *ao* is equal to X'–8. Th at joint 1, *oa* is the supporting force, *ab* is 500 lb and *bf* and *fo* are drawn para respectively to *BF* and *FO*, intersecting at *f*. The external forces and stre act in the direction *oa*, *ab*, *bf* and *fo*, showing that *BF* is in compression and in tension. At joint 2 the stress-lines are *fb*, *bc* equal to 1 000 lb, *cg* and *gf*. stress-lines at joint 3 are *of*, *fg*, *gh* and *ho*; at joint 4, *hg*, *gc*, *cd*, *di* and *ih*; a joint 5, *id*, *de*, *ek* and *ki*. If the load-line has been correctly divided at *o*, the stress-lines have been drawn exactly parallel to the lines of the truss, the p *k* will fall vertically above the point *i*. At joint 6 the stress-lines are *ok*, *ki*, *i* *ho*. As the figure must close by a horizontal line through *o*, it is evident that

the truss-diagram cannot be represented, and therefore there can be this member when the wind is from the left. At joint 7 the reaction acting up, and *ok* and *ke* must close the figure, showing that the line s the stress in the entire length of the right rafter, and that there is the bracing on that side of the truss when the wind is from the left. ver, either the lower chord or the rafter is not straight, some of the at side come into action. By noting the character of the stresses in is seen that the different members of the truss have the same kind is produced by vertical loads. As the wind may blow from either is evident that both sides of the truss must be made alike. This trates the method of drawing the stress-diagram for any truss with fter when both ends of the truss are fixed.

Rollers. Example 32. When one end of the truss is FREE TO action at that end must always be practically vertical, and this es a considerable variation of stress when the wind is on different oof; so that it is necessary to draw two wind-stress diagrams, one



Triangular Truss. Truss-diagram and Stress-diagram, Wind Left

THE LEFT, marked W.L, and one for WIND FROM THE RIGHT, It is customary with authors when writing on this subject to he ROLLERS are always under the right-hand support, and this wed here. In practice the ROLLERS may be placed under either es of the truss are usually proportioned to the maximum stresses. le we will take the same truss-diagram that was used in Fig. 49, gain in Fig. 50, which is drawn to show WIND FROM THE LEFT. -line 1–8 and divide it at X', as in example 31. Draw a line *ae*, the rafter and equal to 1–8 in length, and divide it into two same proportions. Through x' on *ae* draw a horizontal line, vertical line, the two intersecting at *o*. Then *eo* represents the at joint 7 and *oa* the reaction at joint 1. The stress-lines at *ab* equal to 500 lb, *bf* and *fo*. At joint 2: *fb*, *bc*, *cg* and *gf*. The diagram W.L. is completed exactly as described for Fig. 49A, ce between the two being the location of point *o*, which gives in the bottom chord for the truss of Fig. 50. Fig. 51 represents ith WIND FROM THE RIGHT. To draw the stress-diagram W.R. pendicular to the rafter and equal to the total load, 3 000 lb. t x' into two segments of the same proportions as the segments

of the line 1–8, Fig. 50, the longer segment being at the top. To find the rea tions draw a horizontal line through x' and a vertical line through t, the two lin intersecting at o. Then do is the reaction at joint 1, and ot the reaction at joi 10. For this diagram it is better to start with joint 10 and take the forces the reverse order from that in which they were taken before. The stress-lin at joint 10 are ol, ts equal to 500 lb, sn and no; at joint 9, ns, sr, rm and at joint 8: on, nm, ml and lo; at joint 7, lm, mr, re, ek and kl; and at joint

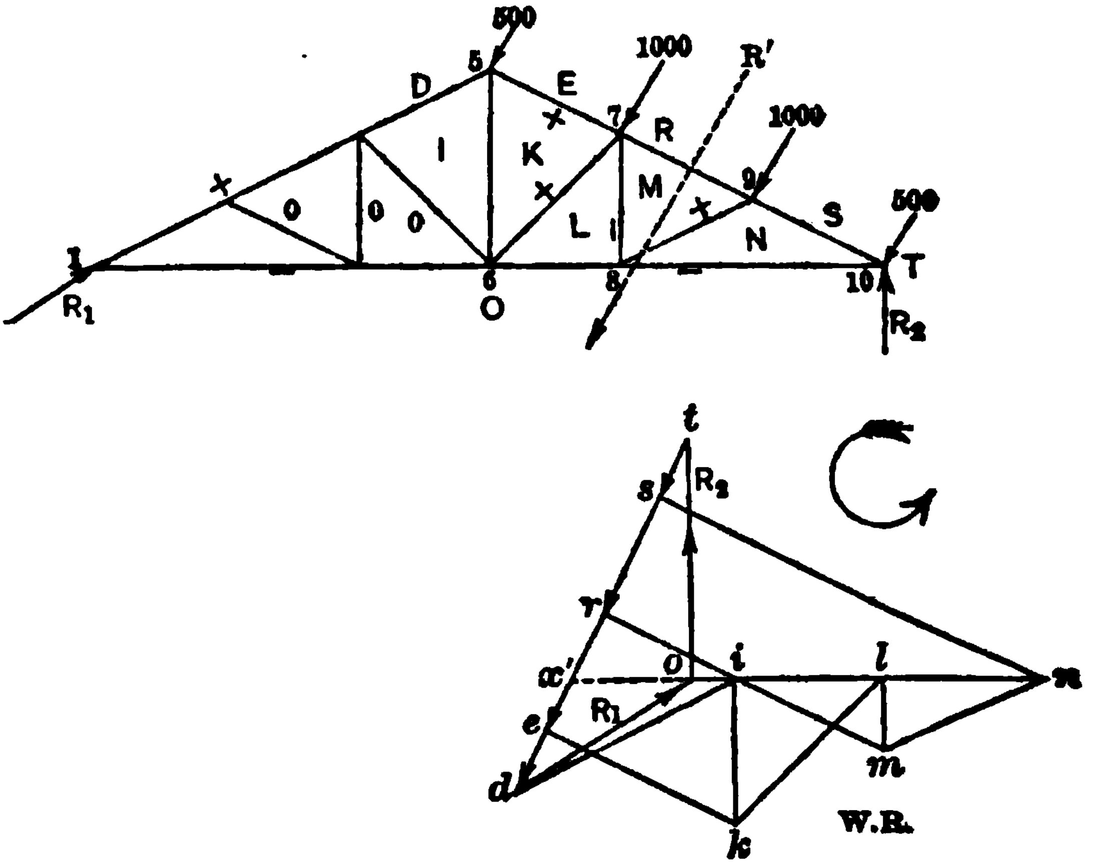


Fig. 51. Triangular Truss. Truss-diagram and Stress-diagram, Wind Right

ke, ed, di and ik. If the diagrams have been correctly drawn the point i fall vertically above the point k. On comparing the two diagrams for W and W.R. it is seen that the stress-lines for the rafters and braces are of the s length and that the stresses are of the same character in both, but that the st in the bottom chord is considerably less when the wind is from the right. T condition does not apply to all trusses, however, so that it is best to draw two stress-diagrams for wind from both directions.

Queen Truss. Example 33. Fig. 52 represents the outline of a QUEEN- TRUSS for a roof having a rise of 14½ in in 12 in. As the truss is of wood supports are considered fixed. Joint 2 divides the rafter into two equal pa consequently the wind-load at this joint is twice that at joint 1 or 4. convenience it is assumed that the wind-load at joint 2 is 1 000 lb and at join and 4, 500 lb. The resultant is 2 000 lb acting through joint 2 and inters the tie-beam at X. To find the supporting forces, draw the line 1–8 equa 2 000 lb and connect 7 and 8. From X draw a line parallel to 7–8 intersec 1–8 at X'. Then 8–X' is R_1 or the supporting force at joint 1 and X'–1 e the supporting force at joint 7. Begin the stress-diagram (Fig. 52A) by dra the line ad at right-angles to the rafter 1–4, and equal in length to 1–8 or 2 oo By means of dividers locate the point o so that oa equals 8–X'. Then the st lines for joint 1 are oa, ab, be and eo; at joint 2, eb, bc, cf and fe; at joint 3 ef, fh and ho; and at joint 4, hf, fc, cd, dk and kh. It is seen that the force-p gon at joint 4 will not close without the brace KH, because the initial poi drawing the polygon is at h, and a horizontal line through d does not

rough h. A QUEEN-ROD TRUSS, therefore, requires braces in the middle panel resist the wind-stress. With the wind from the right, a brace is required from int 3 to joint 6. At joint 5 the stress-lines are oh, hk, kl and lo. It should be ticed that lo acts towards the joint, showing that LO is in compression. At

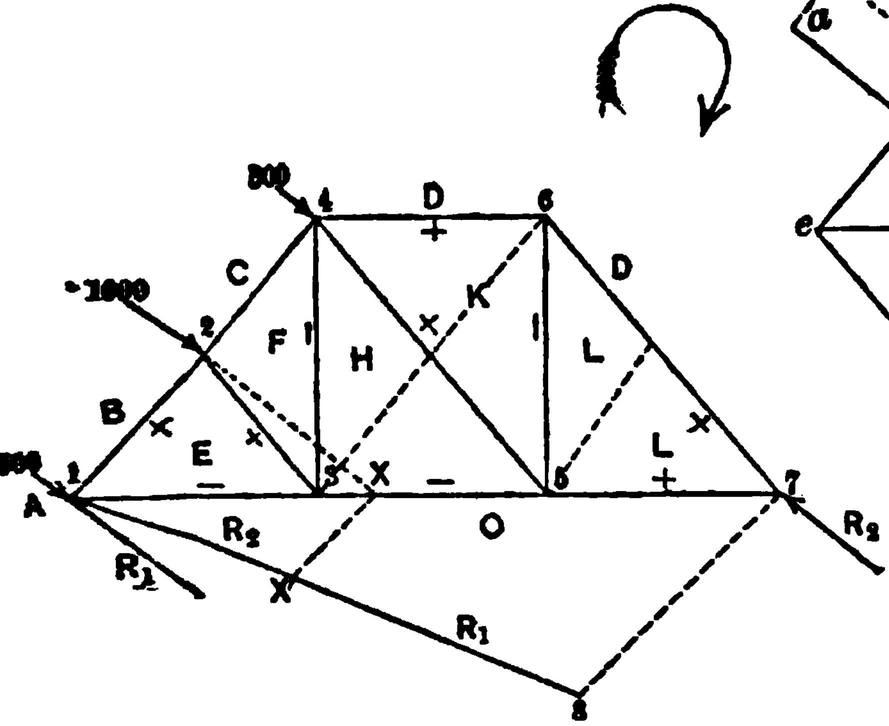

Fig. 52. Queen Truss. Truss-diagram

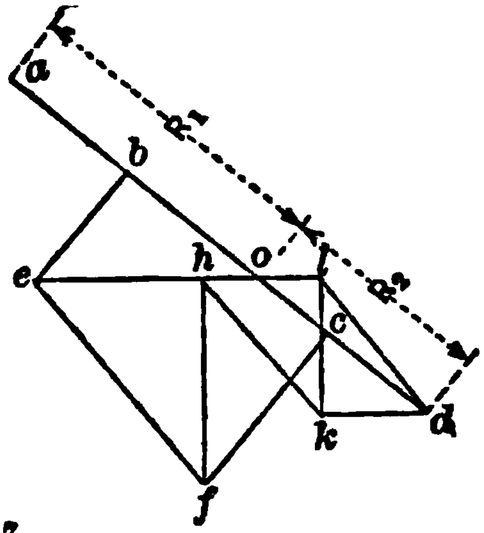

Fig. 52A. Queen Truss. Stress-diagram, Wind Left

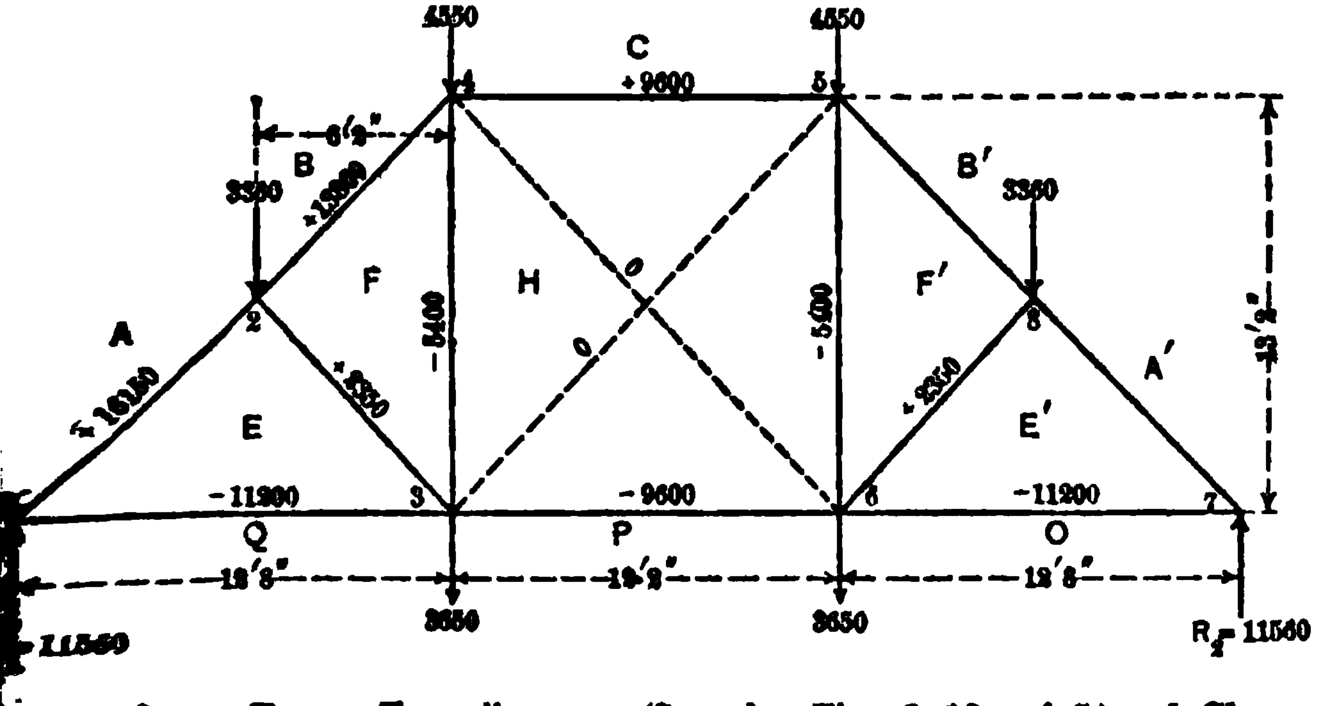
t it would seem as though this could not be true, but if we glance at joint 7 see that R_2 is thrusting in on the joint, and that a strut is required to keep joint in position. This condition is true only when the inclination of the ter is greater than 45°. When the inclination of the rafter is exactly 45°,



53. Queen Truss. Truss-diagram. (See, also, Figs. 3, 12 and 54 and Chapter XXVIII, Fig. 1)

e is no stress in LO, and when the inclination is less than 45°, LO is in ten- The stress-lines for joint 6 are lk, kd and dl. If no errors are made, a through d parallel to DL passes through the point l, previously obtained. A slight inaccuracy in locating the point X', or in drawing the stress-diagram,

however, causes the line through d to pass to one side or the other of point and if this happens, it shows that there has been some inaccuracy somewhe In practice, a slight divergence does not materially affect the stress. At join the sides of the stress-polygon are ol, ld and $do = R_2$, the lines being alrea drawn.

Combination of Stresses. Example 34. For the purpose of showing h the stresses due to wind and vertical loads are COMBINED, the truss-diagrams Figs. 53 and 54 are shown, being the same as in Fig. 12, and representing t

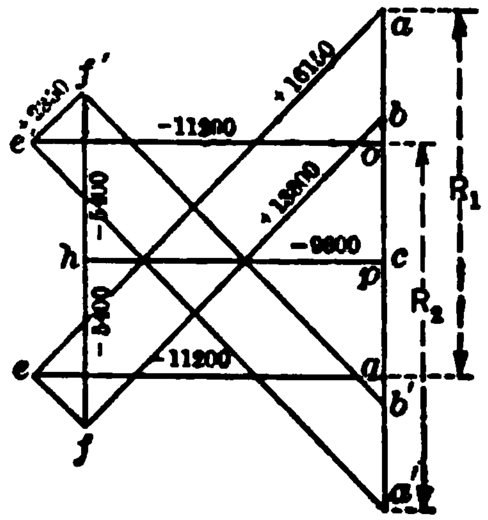


Fig. 53A. Queen Truss. Stress-diagram

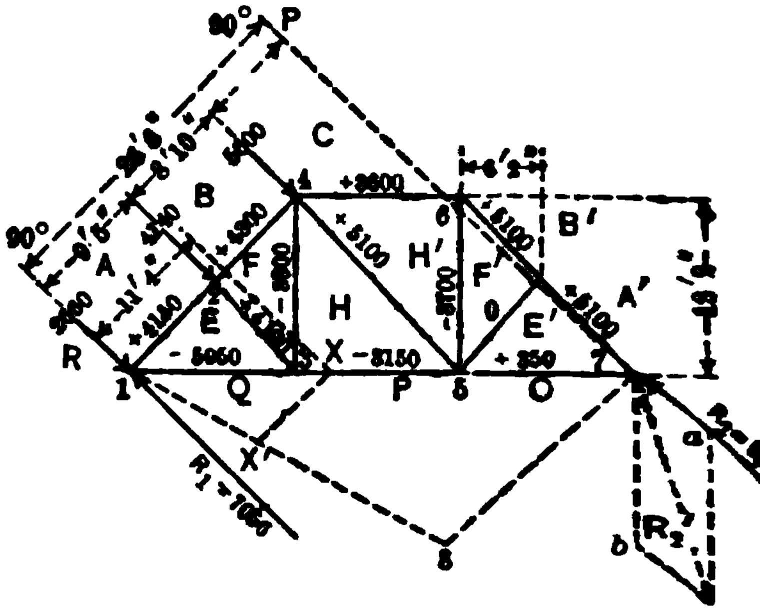

Fig. 54. Queen Truss. Truss-diagram. (See, Figs. 3, 12 and 53 and Chapter XXVIII, Fi

truss shown in Fig. 3. The stresses first determined are those due to the we of the roof and ceiling and to an allowance of 10 lb per sq ft for sleet. page 1055 the roof-area supported at joint 2 was found to be 147½ sq ft an joint 3, 200 sq ft. On page 1055 the weight of the roof was estimated at 12 per sq ft, and allowing 10 lb for sleet, there results 22¾ lb as the greatest load under a heavy wind. This gives 3 360 lb for the load at joint 2 and 4 5 for the load at joint 3. The ceiling-loads will, of course, be the same as in Fi Fig. 53 shows the loads due to weight of materials and sleet, as computed ab and the ceiling-loads. Fig. 53A is the stress-diagram for these loads, with stresses indicated by figures. This diagram is drawn exactly in the same as the stress-diagram in Fig. 12, page 1071.

Wind-Stresses. The inclination of the roof is very close to 45°, and from T IX, page 1053, the normal wind-pressure for that angle is found to be 28 lb. M plying the roof-area at joints 2 and 3 by 28, the wind-loads indicated in Fi are obtained. The wind-load at joint 1, also, must be found. The roo supported at this joint, allowing 17 in for eave-projection (Fig. 3) is 6⅓ by or 95 sq ft, which makes the wind-load 2 660 lb. The next step is to fin point at which the resultant of these loads cuts the rafter. As the load not symmetrical or uniform on the rafter, the point through which the res acts must be determined by means of moments about joint 1. The arms loads at joints 2 and 4 are figured on the truss-diagram (Fig. 54). The mo are

$$4\,140 \text{ lb} \times 9\tfrac{5}{12} \text{ ft} = 38\,985 \text{ ft-lb}$$
$$5\,600 \text{ lb} \times 18\tfrac{1}{4} \text{ ft} = 102\,200 \text{ ft-lb}$$
$$\text{The sum of the moments} = 141\,185 \text{ ft-lb}$$

it is the sum of all the loads, or 12 400 lb, and the distance of its point n from 1 is found by dividing the sum of the moments by the result- 141 185 ft-lb divided by 12 400 lb = 11.4 ft. Measuring off 11.4 ft from joint 1 and drawing a line at right-angles to it intersecting the e point X is determined. From 1 the line 1–8 is drawn at any ual in length to the sum of the loads, 12 400 lb, and 7–8 is drawn. ne is drawn parallel to 7–8, intersecting 1–8 at X'. Then 8–X' is porting force at joint 1 and X'–1 is R_2 or the supporting force at

Forces Computed by Moments. The supporting forces may also by moments. The moments of the loads about joint 1 tend to ss from left to right. To prevent this rotation there is the moment ting force R_2 acting at joint 7 to rotate the truss from right to left. equilibrium, the moment of R_2 about joint 1 must just equal the sum ts of the loads about the same point. This sum was found above to lb. The arm of R_2 is the perpendicular distance between its line l joint 1. Continue R_2 to meet the dotted line at P. The dis- ce RA to P scales, say 26.5 ft. (By trigonometry, 26 ft.) Knowing alue of R_2 is obtained by dividing the oments of the loads, 141 185, by the t. This gives 5 344 lb. As the sum must equal the total load, R_1 equals 344 lb, or 7 056 lb. The distance should scale reasonably close to these ring the supporting forces, the stress- 54A, is drawn exactly as described for the inclination of the rafters is a han 45°, OE' is in compression, but ery small. The figures on Fig. 54A resses in pounds. The stresses may ited and should be arranged as in the following table. In wind-stresses, it should be remembered that the wind may blow de of the truss, and the greatest stress liable to occur should be

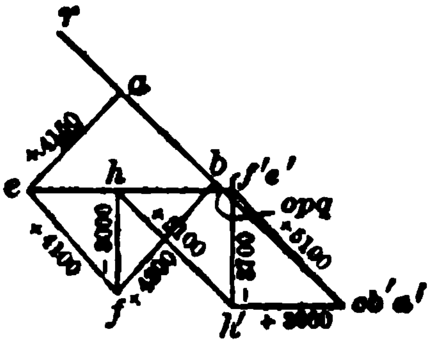

Fig. 54A. Queen Truss. Stress-diagram, Wind Left

.

II. Stresses for the Trusses Shown in Figs. 12, 53 and 54

	Dead weights and sleet (Fig. 53A)	Wind-stresses (Fig. 54)	Totals	Stresses (Fig. 12)
.	+16 150	+5 100	+21 250	+25 600
.	+13 800	+5 100	+18 900	+21 300
.	+ 9 600	+3 600	+13 200	+14 700

.	−11 200	−5 950	−17 150	−17 600
.	− 9 600	−3 150	−12 750	−14 700

rs are lettered as in Fig. 54. Thus the stress in the rafter $F'B'$ the rafter on the other side, and this stress acts through the he rafter; hence the stress for AE and BF should be entered tress in $F'B'$. In the same way the stress in the rod $H'F'$ is

greater than in FH; hence the stress in $H'F'$ should be tabulated. The stre in OE' slightly reduces the tension due to the dead load, but as the stress in E increases it, the stresses in EQ and HP should be tabulated. Both sides of t truss should of course be made alike, and two braces should be inserted in t middle panel. In the fifth column of the table are given the stresses due to t ceiling-load and a vertical load on the roof of 42¾ lb per sq ft, as obtained fro the stress-diagram, Fig. 12. Comparing the stresses in the fourth and fif columns, it is seen that except for the brace EF, and for the two rods, the stres obtained by combining snow and wind and adding to the dead weight are great than the totals due to wind, dead weight and sleet. Vertical loads, of cour cause no stresses in the braces of the middle panel, and unless the wind-stres are drawn, it is necessary to estimate the sizes of these braces. The stresses these braces, however, are so small that large pieces of timber are not requir The stresses given in the fourth column are unquestionably nearer what t real stresses are likely to be than those in the fifth column. If the roof is erect in a warm climate where there is no sleet, these stresses may be further reduc by omitting the 10 lb per sq ft added for sleet. If, on the other hand, the clination of the roof is less than 30°, the stresses produced by a heavy fall snow without wind generally exceed the sum of those due to dead weight, sl and wind; and for such roofs the stresses due to the maximum snow-load sho always be computed.

Reactions. The reactions, or supporting forces of the truss shown in Fig. are very much inclined from the vertical. As the dead load, however, is alwa acting on the truss, the inclination of the real reaction is never so great, more nearly vertical; and when there is no wind the reactions are exactly v tical. The theoretical reaction, due to both wind-load and dead load, is diagonal of a parallelogram, the two adjacent sides of which are the reacti for the dead load and wind-load drawn to the same scale. Thus if a–7, Fig. represents the reaction due to the wind and b–7 the vertical reaction, due to dead load and drawn to the same scale, then R'_2 is the resultant reaction, modif somewhat, however, by friction. Examples 31, 32 and 33 serve to show general method of drawing WIND STRESS-DIAGRAMS, and are sufficient to ena the student to draw those diagrams for most trusses with straight rafters. trusses with curved rafters the diagrams become more complicated, and reader is referred to Graphical Analysis of Roof Trusses, by Charles E. Gre and to other standard handbooks on the subject.

7. Trusses with Knee-Braces

Knee-Braces are generally used to give greater stability to the structure whole when roof-trusses are supported by COLUMNS. Under the action vertical loads the stresses in these members are usually assumed as zero, wh would be true if the materials composing the TRUSS, KNEE-BRACES and COLU were rigid. This discussion will deal, however, with the effect of wind blo against one side of the building and roof. The ACTUAL STRESSES in the k braces, columns and truss-members will probably never be known exactly there are so many VARIABLE FACTORS entering into the problem. In the u construction, in which columns are bolted to masonry pedestals at the bott either riveted or bolted to the trusses at the top, and in which the knee-br are riveted at both ends, the degree to which these connections may be consid FIXED is a question leading to many arguments and differences of opinion. will not be discussed at all; but it will be shown how the stresses in all mem of the framework can be found under given assumptions. Assume, for exam that the bottoms of the columns are sufficiently FIXED, so that a point of

midway between the bottom of the knee-brace and the masonry
uivalent to assuming a PIN at this point), and so that the top attach-
those of the knee-braces may be considered as PIN-CONNECTIONS.
russ and loading shown in Fig. 55, it is clear that the outside forces

ctions at M and N are TX and YT, respectively. The next step
ect of these reactions at the points O, Q, P and R. The vertical
and V_2 act as vertical forces at O and P. The horizontal com-
bending moments at O and P, and, in effect, horizontal forces
R. Taking the left column, the 8 100 lb acting towards the left
column to the left if not prevented by the joints at O and Q.

If the member MQ is considered to act as a lever with a fulcrum at O, a hor zontal force of 8 100 lb acting towards the left at M will produce a pressure, or force acting from left to right at Q which equals, by the method of moments, th center of moments being at O, 8 100 lb × 7.5 ft ÷ 5 ft = 12 150 lb. At O, in li manner, taking the center of moments at Q, 8 100 lb × 12.5 ft ÷ 5 ft = 20 250

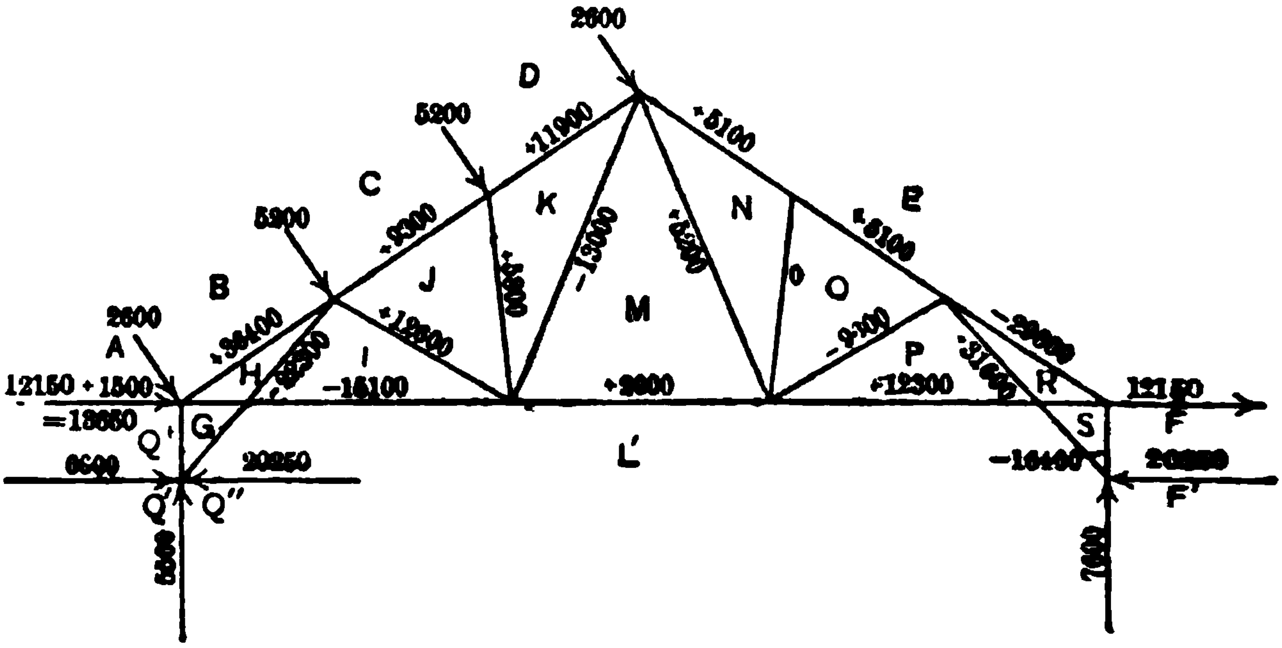

Fig. 56. Truss with Knee-braces. Truss-diagram

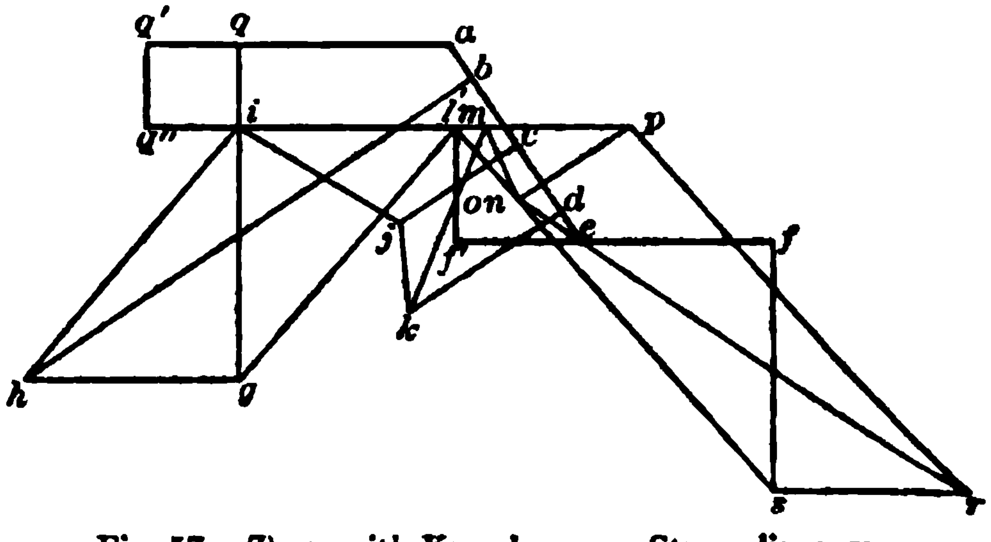

Fig. 57. Truss with Knee-braces. Stress-diagram

is produced, acting from right to left. These forces are shown in Fig. 56. Wh combined with those shown in Fig. 55 they give the forces acting at O, Q and P which are used in constructing the stress-diagram shown in Fig. 57.

8. Arched Trusses

An Arched Truss is one which has the FORM OF AN ARCH and which is supported at the ends that the reactions produced by vertical forces are verti This is usually accomplished by placing PIN-CONNECTIONS at the supports a providing ROLLERS at one end to permit horizontal movement.

Stresses in an Arched Truss. The determination of the stresses in members of an ARCHED TRUSS is readily accomplished by following the meth given in the previous examples.

Arched Truss with Roller-Support. Example 35. In Fig. 58 is sh the left half of an ARCHED TRUSS and the ROLLER-SUPPORT. This truss has shape and dimensions of a truss in the Live Stock Pavilion, Union Stock-Y

and Transit Company, Chicago, Ill. It is discussed in the Engineering News of June 28, 1906. The loading shown is symmetrical about the middle of the span and hence each reaction equals one-half the total load. Fig. 58A shows

Fig. 58. Live Stock Pavilion, Chicago, Ill. Truss-diagram

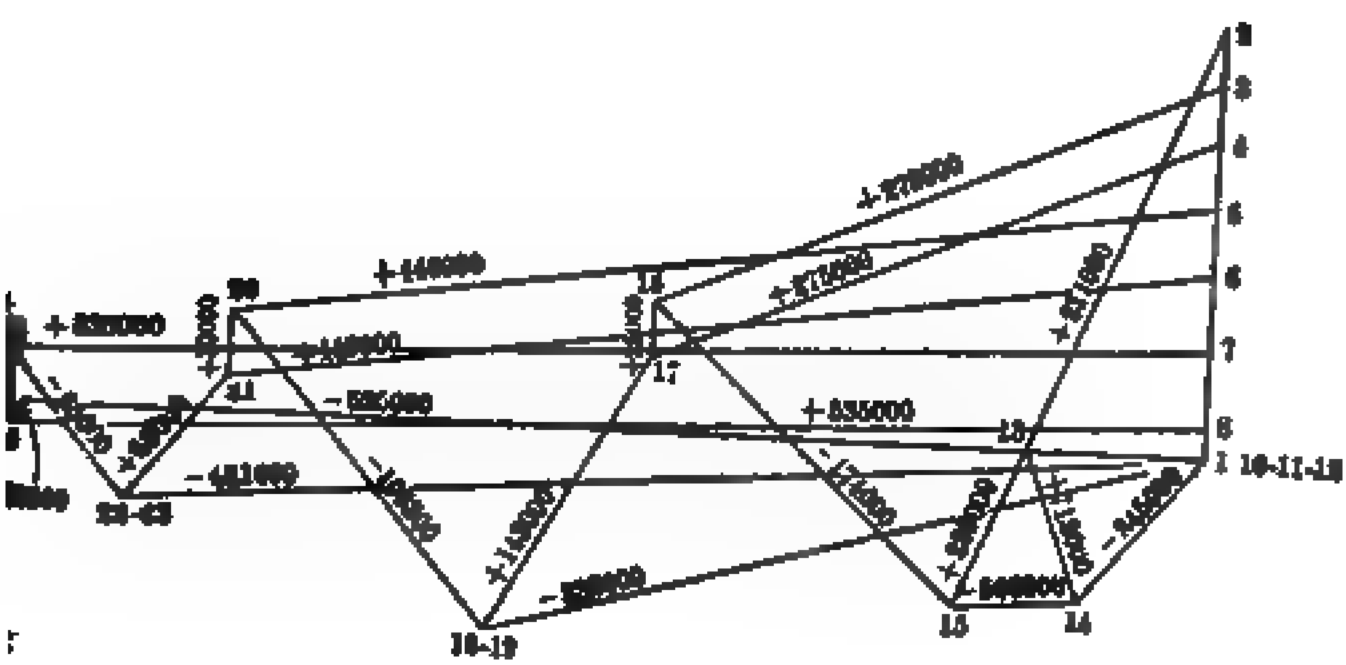

Fig. 58A. Live Stock Pavilion, Chicago, Ill. Stress-diagram for Truss

stress-diagram for one-half of the truss. The stresses upon the right of the ... are the same as those upon the left.

... HORIZONTAL DEFLECTION of this truss is measured by the movement of ...ROLLER-END. This movement is computed in the manner explained for the ... TRUSS, pages 1085–7, by the formula $D = \Sigma(Sul \div AE)$. Where D is the

HORIZONTAL MOVEMENT, S the stress in any member as given by the stress-diagra shown in Fig 58A, u the stress in any member produced by the unit load appli at the roller end of the truss and acting in a horizontal direction (Fig. 58B l the length of any member, A the area of any member, E Young's modulus elasticity for the material composing any member and Σ the sign of summatio and when limits are not designated, the formula indicates that $\Sigma(Sul \div AE)$ is be taken for each member of the truss. For the loads and areas indicated Fig. 58, the rollers will move about 10 in wh E is 30 000 000 lb per sq in. In order that given span may obtain under a given lo each tension-member must be construct shorter than its geometrical length by amount which it is lengthened by the str which it resists, and each compression-memb must be lengthened in a like manner. A other loading will produce a change in length of the span. To reduce the HORIZONT DEFLECTION without changing the lengths the members they would have to be made excessively heavy. A truss of t form shown in Fig. 58 is not economical as an ARCHED TRUSS on rollers b may be satisfactorily used by connecting the two end-pins by a TIE-ROD.

Fig. 58B. Live Stock Pavilion, Chicago, Ill. Stress-diagram

Arched Truss with Tie-Rod. When a TIE-ROD is employed the memb become much lighter and can be built according to their geometrical lengt The stress in the TIE-ROD may be found from the formula

$$S_t = \sum \frac{Sul}{AE} \div \left\{ \sum \frac{u^2l}{AE} + \frac{l'}{A'E'} \right\}$$

in which S_t is the stress in the tie-rod, A' the area of the tie-rod, l' the length the tie-rod and E' Young's modulus of elasticity for the material compos the tie-rod. The other symbols have the significance given above for expression for D. Since the stress and area of the tie-rod appear in the ab equation it is necessary to assume an area and then compute the value of If this produces a unit stress in the tie-rod differing greatly from the allowa value, a new trial must be made. Having found the stress in the tie-rod, resulting stresses in the truss-members can be found graphically from a str diagram which will be of the form shown in Fig. 58B, which was constructed a horizontal force of 1 000 lb. The stresses can be found, also, by multiply the stresses produced by one pound by the value of S_t. The stresses produ by S_t combined algebraically with those obtained from Fig. 58A give the fi stresses. These stresses differ but little from those which obtain for a T HINGED ARCH of the form shown in Fig. 58, and such structures with the t ROD are often classed as TWO-HINGED ARCHES

Assumption of Areas. Since the DEFLECTION of the truss shown in Fig. depends upon the AREAS of the members, it is evident that they must be ei known or assumed before the formulas for D or S_t can be applied. For a structure the AREAS are of course unknown and the problem of determining stresses becomes one which is sometimes classed as CUT-AND-TRY. For the trial, the areas may be assumed as unity and the corresponding value o found and then the combined stresses. The members may now be designe to area and a new trial made with these areas. Usually the second tri sufficient, as a slight change in areas does not materially affect the va of S_t.

9. Trussed Arches

Symmetrical Trussed Arches. The THREE-HINGED ARCH is the simplest form of TRUSSED ARCH, and, as used in buildings, it is usually symmetrical in form, consisting of two trusses connected by a pin over the middle of the span and resting on a pin at each support. The stresses in the truss-members are found by the ordinary graphical methods after the reactions have been determined.

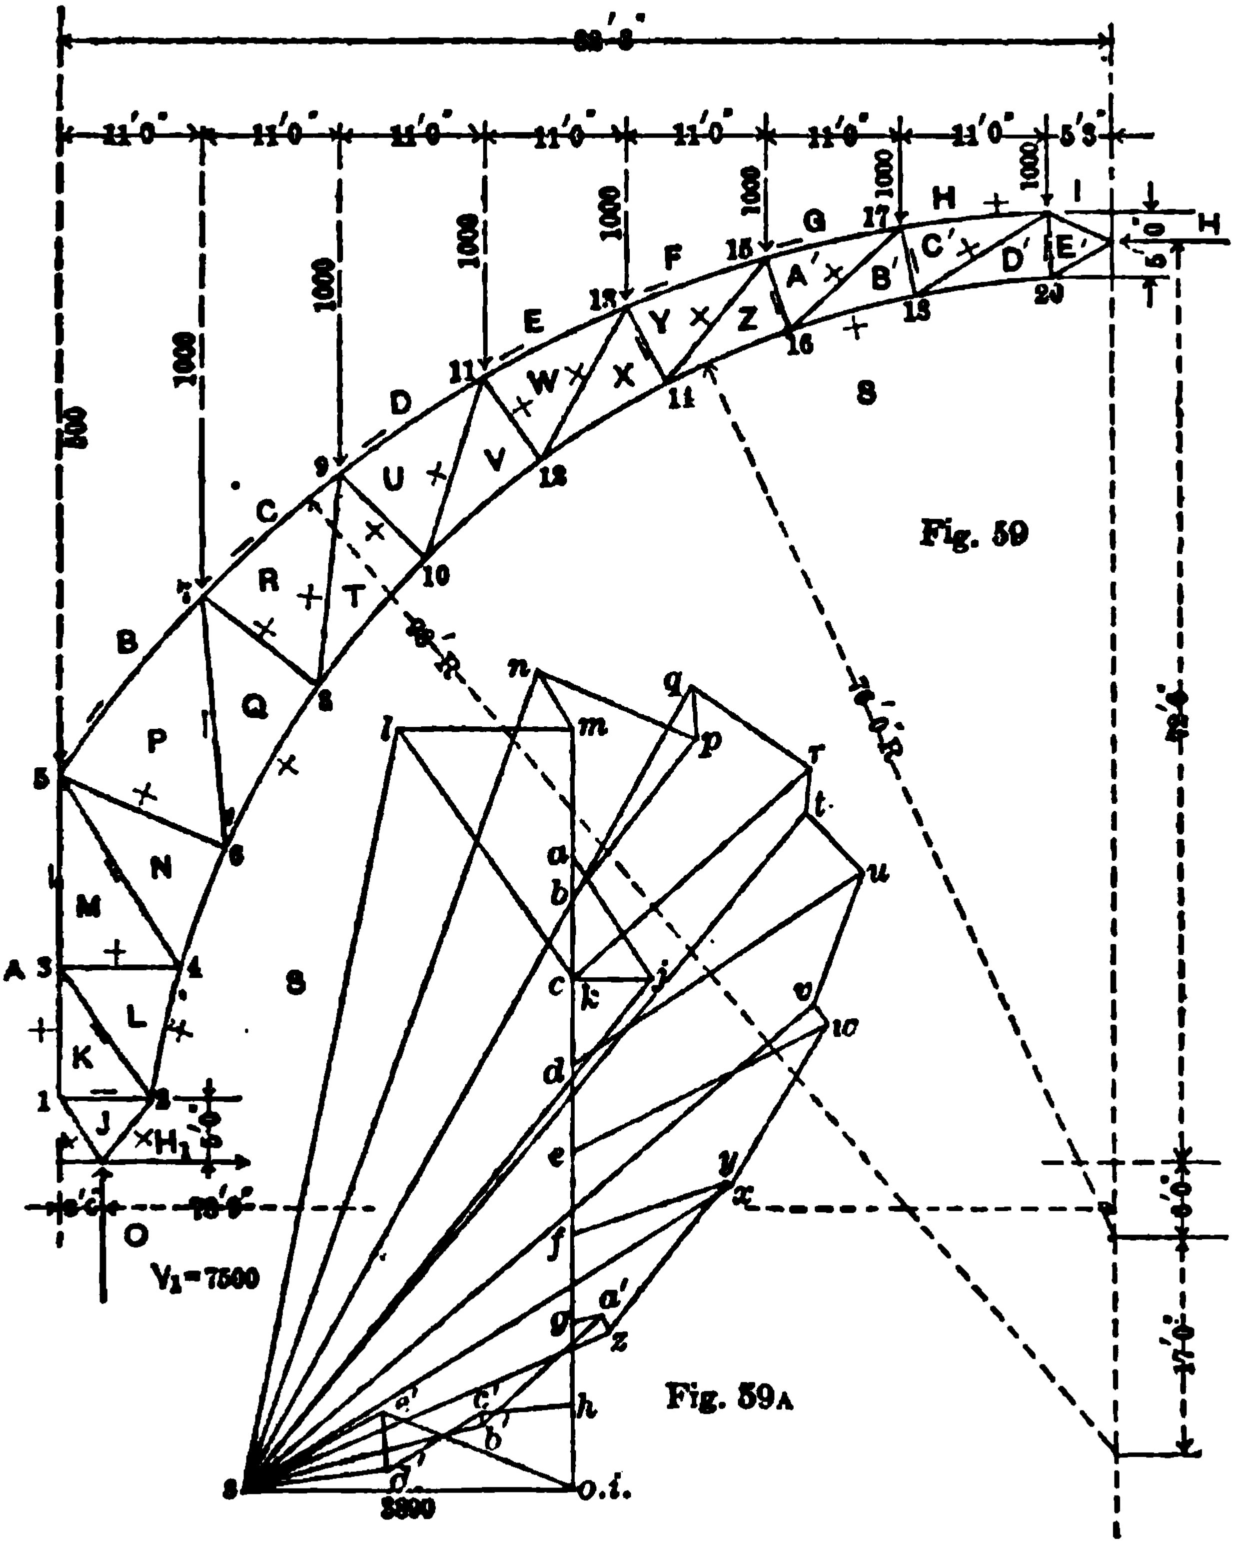

Fig. 59. Three-hinged Arch. Truss-diagram
Fig. 59A. Stress-diagram

The SUPPORTING FORCES are inclined and may be resolved into two components, one vertical and the other horizontal. For symmetrical loading the two reactions are equal in magnitude. The vertical components are each equal to one-half the vertical loading. The horizontal components are equal in magnitude and opposite in character. The following examples illustrate the methods to be followed in the determination of the stresses.

Trussed Three-hinged Arch. **Example 36.** Fig. 59 shows one-half o TRUSSED THREE-HINGED ARCH with a vertical load of 1 000 lb per top-ch joint. Fig. 59A shows the stress-diagram for this loading; but before it can drawn, the vertical and horizontal reactions at the left support must be det mined. The vertical reaction is $(7 \times 1\,000) + 500 = 7\,500$ lb or one-half the v tical load. The horizontal component or the HORIZONTAL THRUST of the a may be found by moments. The center of moments will be taken at the mid

Fig. 60A. Stress-diagram

pin at the crown as at this point the moment is zero. The equation of mome is $H_1 \times 72.5 + 1\,000\,(5.25 + 16.25 + 27.25 + 38.25 + 49.25 + 60.25 + 71.25)$

$$+ 500 \times 82.25 - 7\,500 \times 78.75 = 0,$$

or

$$H_1 = 281\,750 \div 72.5 = 3\,886 \text{ lb}$$

Having determined V_1 and H_1, the stress-diagram shown in Fig. 59A ca readily constructed. Since the arch is symmetrical, it is necessary to draw one-half the stress-diagram. If the right half of the arch is removed and i place a horizontal force applied at the middle pin, the magnitude of this forc

: HORIZONTAL THRUST H_1, since, for equilibrium, the algebraic sum
zontal forces is zero.

Three-hinged Arch. **Example** 37. Fig. 60 represents one-half of
THREE-HINGED ARCH used in the Liberal Arts Building of the Colum-
tion, Chicago, Ill., 1893. (See Engineering Record, July 9, 1892.)
the stress-diagram for the loading shown in Fig. 60.

tion of Stresses. In Examples 35 and 36 only the effect of vertical
een considered. Where THREE-HINGED ARCHES are employed they
igned to carry dead, snow and wind-loads. The dead and snow-

al loads but the snow-load is not symmetrical in all cases. The
ually considered as acting normal to the roof. In order to be
aximum stresses are obtained, the stresses for the following com-
g must be found and combined

AD LOAD only,
OW-LOAD covering left half of roof,
OW-LOAD covering right half of roof,
ND-LOAD acting normal to roof on left of center,
ND-LOAD acting normal to roof on right of center.

Fig. 61B. 5th Regiment Armory, Baltimore, Md. Stress-diagram

Fig. 61C. 5th Regiment Armory, Baltimore, Md. Stress-diagram

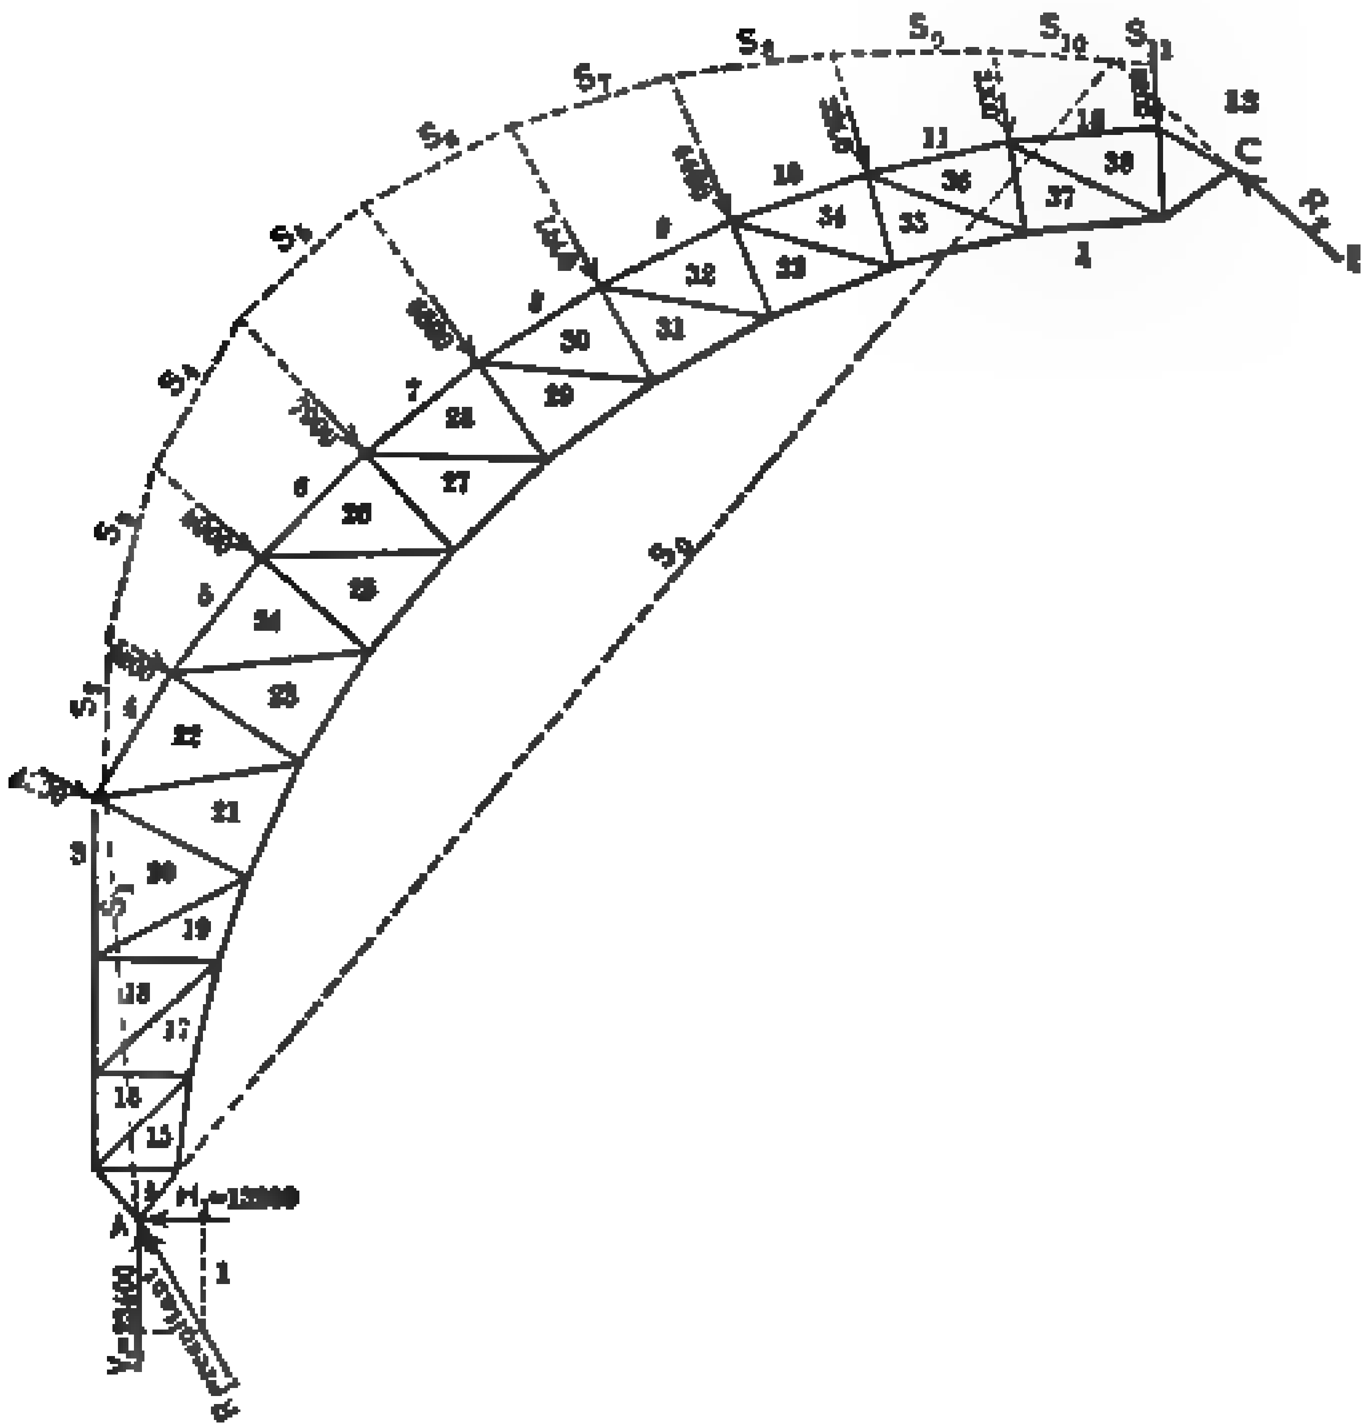

Fig. 61D. 5th Regiment Armory, Baltimore, Md. Truss-diagram

esses for the above conditions of loading are to be found for one-half h. In combining the stresses those which occur at the same time are d in determining maximums. Many engineers do not consider snow loads acting on the same portion of the roof simultaneously.

d **Three-hinged Arch.** **Example 38.** Fig. 61 shows one-half of a HREE-HINGED ARCH with the dead, snow and wind-loads indicated at e upper-chord joints. This form of truss supports the roof of the nent Armory, Baltimore, Md., described in the Engineering Record , 1904. The stresses for the loadings specified above will be deter- it will be shown how these are to be combined.

ad Stresses. The reactions are obtained by the method used in 5. V_1 is 77 900 lb and H_1 32 000 lb. Fig. 61A is the stress-diagram nbers shown in Fig. 61.

Left Half of Span. Assuming that the snow covers the portion of own in Fig. 61 and taking the center of moments at the middle pin, y moments that V_1 is equal to 26 700 lb and H_1 is equal to 15 000 lb. t the support the stress-diagram shown in Fig. 61B is readily drawn.

Right Half of Span. With the snow on the right of the crown, the the span shown in Fig. 61 is unloaded. The total snow-load is nd it has just been found that the vertical reaction at the support the loading is 26 700 lb; hence the vertical reaction at the other 1 200 less 26 700 lb or 14 500 lb or V_1 for the case considered. Since at the middle pin is zero, V_1 (half the span) less H_1 (rise of the arch) or $14\,500 \times 95.16 - H_1 \times 92.0 = 0$; and $\times 95.16) \div 92 = 15\,000$ lb which is the nd above. As before, beginning at the , the stress-diagram is constructed as . 61C.

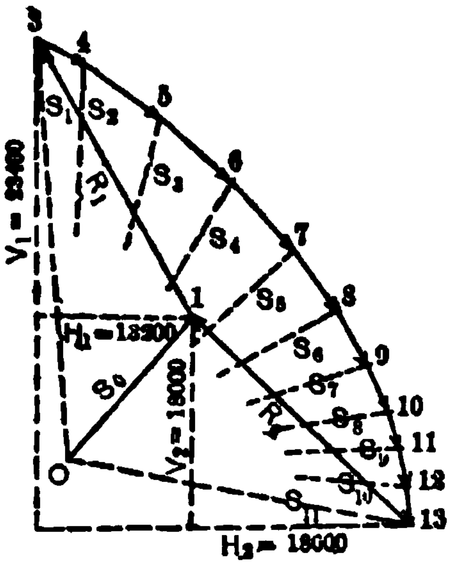

Fig. 61E. 5th Regiment Armory, Baltimore, Md. Force polygon

ering Entire Span. The algebraic sum es found from the two cases above for vill give the stresses produced by a vering the entire span.

on Left of Crown. Here no two of parallel. This condition increases the ng the reactions. These may be com- oments, but a graphical method is onvenient. The direction and mag- resultant of the wind-forces are first hics. As shown in Fig. 61E, the wind- off in order. Then 3–13 is the direc- itude of the resultant. Next, from any point O draw the strings and construct the equilibrium polygon shown in Fig. 61D, begin- ing string S_1 from A, and so on until string S_{11} cuts the line BC gh the middle pin and the pin at the right support. This is the e reaction at the right support. In Fig. 61E, from 13 draw a line and from O a line parallel to S_0 in Fig. 61D, and prolong them until . Then 1–3 is the reaction at A and 13–1 that at the right support. se into vertical and horizontal components, V_1 equals 23 400 lb, 00 lb, V_2 equals 18 000 lb and H_2 equals 18 600 lb. Fig. 61F shows ram from the left support up to the crown.

on Right of Crown. Since the reaction at A, Fig. 61D, produced ust pass through the hinges, or pins A and C, the stress-diagram

will be exactly similar in shape to that shown in Fig. 61C; but the values of I and H_2 will be 18 000 lb and 18 600 lb respectively. The stresses will bear direct proportion to the stresses found from Fig. 61C, and hence a new diagra is not necessary.

20 21

Fig. 61F. 5th Regiment Armory, Baltimore, Md. Stress-diagram

Combination of Stresses. The maximum stresses may now be determine To illustrate the method, consider the lower chord 1–37.

	lb
(*a*) DEAD-LOAD stress,	+ 22 100
(*b*) SNOW on left of crown,	− 14 300
(*c*) SNOW on right of crown,	+ 37 800
(*d*) WIND-LOAD on left of crown,	− 31 600
(*e*) WIND-LOAD on right of crown,	+ 46 900
(*f*) SNOW over all,	+ 23 500
Total stress without wind,	+ 59 900
(*a*) + (*e*),	+ 69 000
(*a*) + (*d*),	− 9 500

The maximum stresses are 69 000 lb compression and 9 500 lb tension, assu ing that the wind and snow-loads are not considered to act on the same side the crown. If no such restriction is made, the maximum stresses are 106 800 compression and 23 800 lb tension. In a like manner the maximum stress each member of the truss is determined. Tables XIX and XX give the MA IMUM STRESS for the members shown in Fig. 61.

Stress-Diagrams for Three-hinged Arches. The STRESS-DIAGRAMS in t above cases are very difficult to construct owing to the great number of li and the difficulty in drawing them exactly parallel to the lines of the tru diagram. One or more members should be computed as a check on the grap ical work

Three-hinged Arch with Tie-Rod. The introduction of a TIE-ROD conne ing the end-pins of a THREE-HINGED ARCH and placing ROLLERS under one e

changes the ARCH into a SIMPLE TRUSS composed of three members,
l rafters and a horizontal tie. Under vertical loading, the support-
ire vertical, but for wind-loads the supporting force at the end with-
is inclined. The stresses in the truss-members are the same as found
he THREE-HINGED ARCH. The stress in the tie-rod equals the hori-
st found above at the roller-end for the given loading. The support
-end is designed for vertical forces only, while the support at the other
sist the vertical reaction and the total horizontal component of the
g on the structure, or for roofs the horizontal component of the wind-
is is very much smaller than the horizontal force which must be

* By proportion, 18 600 : 15 000.

Changes in Temperature do not seriously affect the stresses in the memb of a TRUE THREE-HINGED ARCH, or one with a tie-rod and rollers at one e as the change in geometrical shape is quite small. For the arch with a tie- and no rollers, the effect of changes in temperature may affect the support forces if the tie-rod is not so protected that it will change but little from average temperature. In most structures this is the case as the tie-rod is in under the floor of the building.

The Two-hinged Arch differs essentially in construction from the THR HINGED ARCH in having only two pins or hinges which are placed at the suppo Fig. 62 shows the form of truss which will be used in explaining the method finding the stresses in the members of the truss.

Supporting Forces. The SUPPORTING FORCES are inclined but can be solved into vertical and horizontal components. The vertical components readily found as they are the same as for a simple truss on two supports. horizontal components depend upon the AREAS of the members and their MOD OF ELASTICITY when the dimensions of the truss and the loading are known.

tal Thrust for Vertical Loads. This can be found from the formula

$$H_1 = \sum \frac{Sul}{AE} \div \sum \frac{u^2 l}{AE}$$

ymbols have the significance given on page 1086. But this contains n area A for each piece. For a preliminary trial the procedure is as the truss shown in Fig. 62, divide the span into twenty equal parts :enters of the divisions erect verticals. Through the points on these dway between the chords of the truss, draw a smooth curve as shown. ll be designated the AXIS OF THE ARCH. Number the points desig-

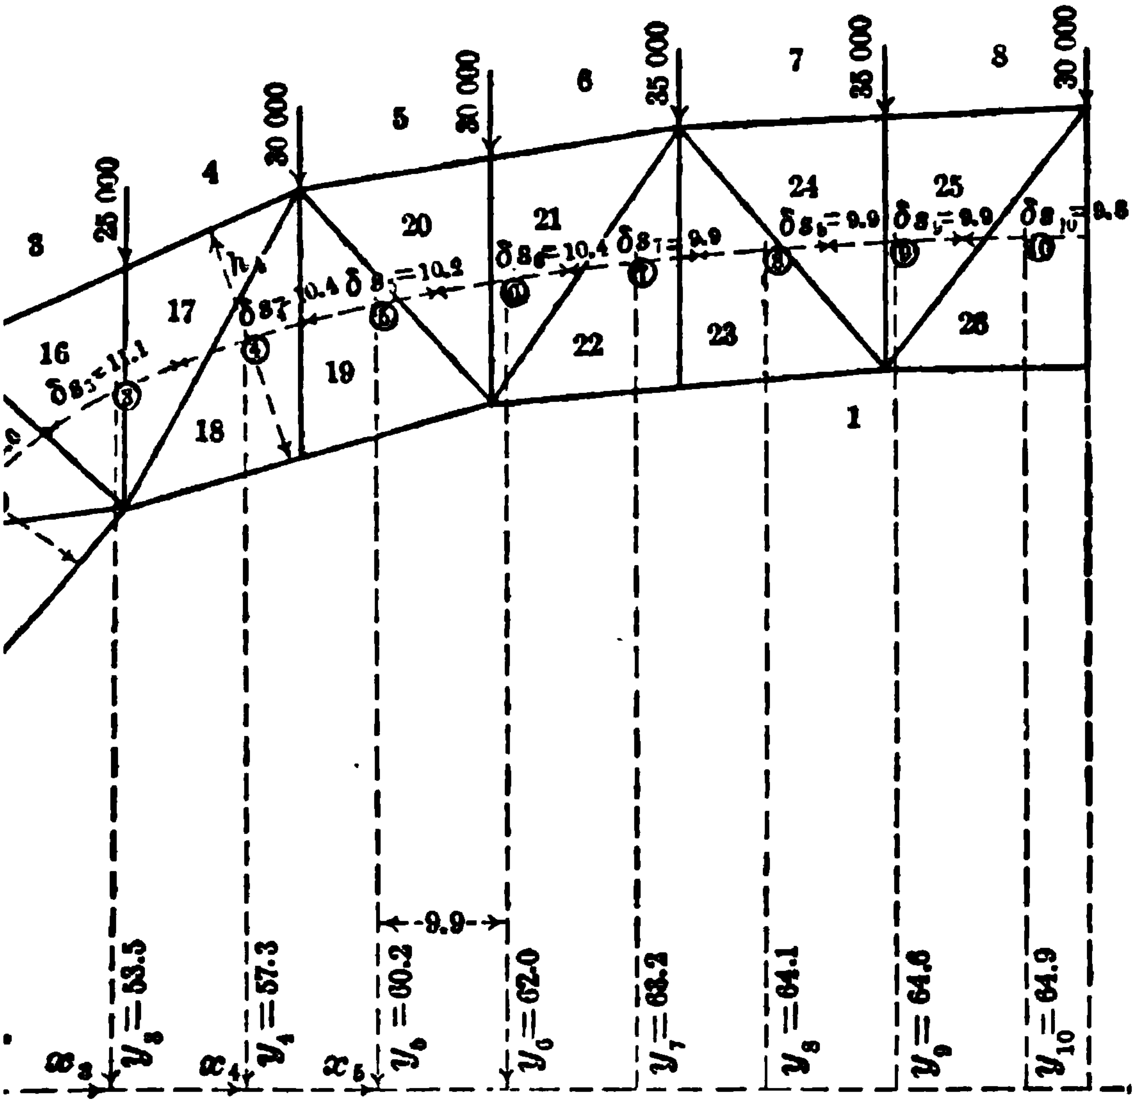

Fig. 62. Two-hinged Arch. Truss-diagram

:, 2, 3, etc., as shown in Fig. 62, and let x and y be their coördi- left support as the origin. Scale the length of the curve between the divisions so that y is practically the ordinate of the center of h of curve, and call this length of the curve δs. On a radial line iumbered 1, 2, 3, etc., scale the distances between the upper and calling the distance h and compute $\frac{1}{2} h^2 = I$, which expresses, the MOMENT OF INERTIA of the section when the chord-areas the web-members are neglected. Let M represent the BENDING point having the abscissa x, of the loads, considering the truss as on two supports; or, for a single load P, $M = Rx - P(x - a)$, than a, where a is the distance of the load P from the left sup- $\delta s \div EI$ is represented by ϕ the HORIZONTAL THRUST can be found ıla,

$$H_1 = \Sigma M y \phi \div \Sigma y^2 \phi$$

For the vertical loading shown in Fig. 62, the value of H_1 is 108 000 lb, and V_1 being one-half the total load, is 195 000 lb. The stresses in the members of the truss can now be found by the usual graphical method. The snow-load, if any must be treated in a like manner. The computations are considerably shorter since $\Sigma y^2\phi$ remains unchanged, regardless of the loading.

Wind-Loads. For WIND-LOADS the process is not changed very much. The value of M is the moment of the wind-loads, assuming the truss as HINGED at the right support and on ROLLERS at the left support. The value of V_1, which is vertical, is found by taking the sum of the moments of the wind-loads about the hinge at the right support and dividing this by the length of the span. The value of H_1 is found from the formula given above, and then the stresses are found by the ordinary stress-diagram. The MAXIMUM STRESSES are now found and the proper AREAS of the members determined.

The True Horizontal Thrust. The method just given is a close approximation to determine the AREAS of the pieces so that the correct formula for H_1 can be applied. This formula is

$$H_1 = \sum \frac{Sul}{AE} \div \sum \frac{u^2l}{AE}$$

where the symbols have the meaning already given. Applying this formula for the dead load shown in Fig. 62 and AREAS shown in Fig. 58, the value of H_1 is 110 600 lb, which is but little different from the value found by the approximate method.

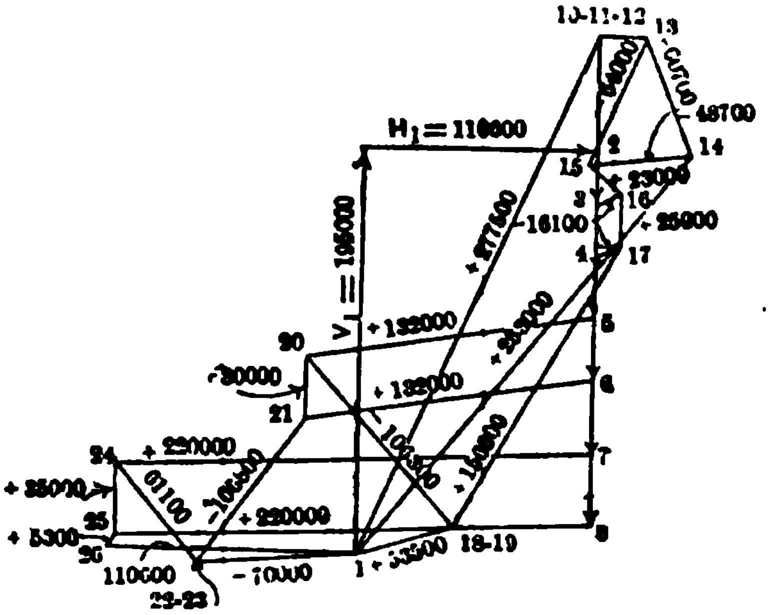

Fig. 62A. Two-hinged Arch. Stress-diagram

Dead-Load Stresses. The stress-diagram for the DEAD LOAD is shown in Fig. 62A. Considerable care must be exercised in drawing the stress diagrams, and their correctness should be checked by computing the stresses in one or more pieces. Compare Fig. 62A with Fig. 58A.

Changes in Temperature. Unlike the THREE-HINGED ARCH the TWO-HINGED ARCH is affected by CHANGES IN TEMPERATURE and the stresses which are produced by such changes must be provided for. $V_1 = O$ and H_1 is determined from the formula

$$H_1 = et^\circ L + \sum \frac{u^2l}{AE}$$

where e is the COEFFICIENT OF EXPANSION for the material composing the truss, t° the number of degrees CHANGE IN TEMPERATURE and L the SPAN of the truss. The other symbols have the significance already given. The above formula assumes that the truss-members are of the same kind of material. After H_1 has been found, the stresses can be determined by constructing the stress-diagram which will be of the shape shown in Fig 58B.

Tie-Rod. If a TIE-ROD connects the two supports of a TWO-HINGED ARCH the remarks made concerning such an arrangement for the THREE-HINGED ARCH apply here.

ted Arch has no hinges and is a type which is seldom employed by in the truss-form. The rigid analysis of a TRUSSED FIXED ARCH is und tedious, so a few formulas will be given, necessary for the solution WITH SOLID WEBS, such as PLATE-GIRDER ARCHES. These formulas plied to truss-forms, where the chords are approximately parallel, rious error. Midway between the top and bottom chords draw a ve, called the ARCH-AXIS, and designate the distance between its ends SPAN OF THE AXIS. Divide the span into n equal parts and at the these divisions draw perpendiculars until they cut the arch-axis.

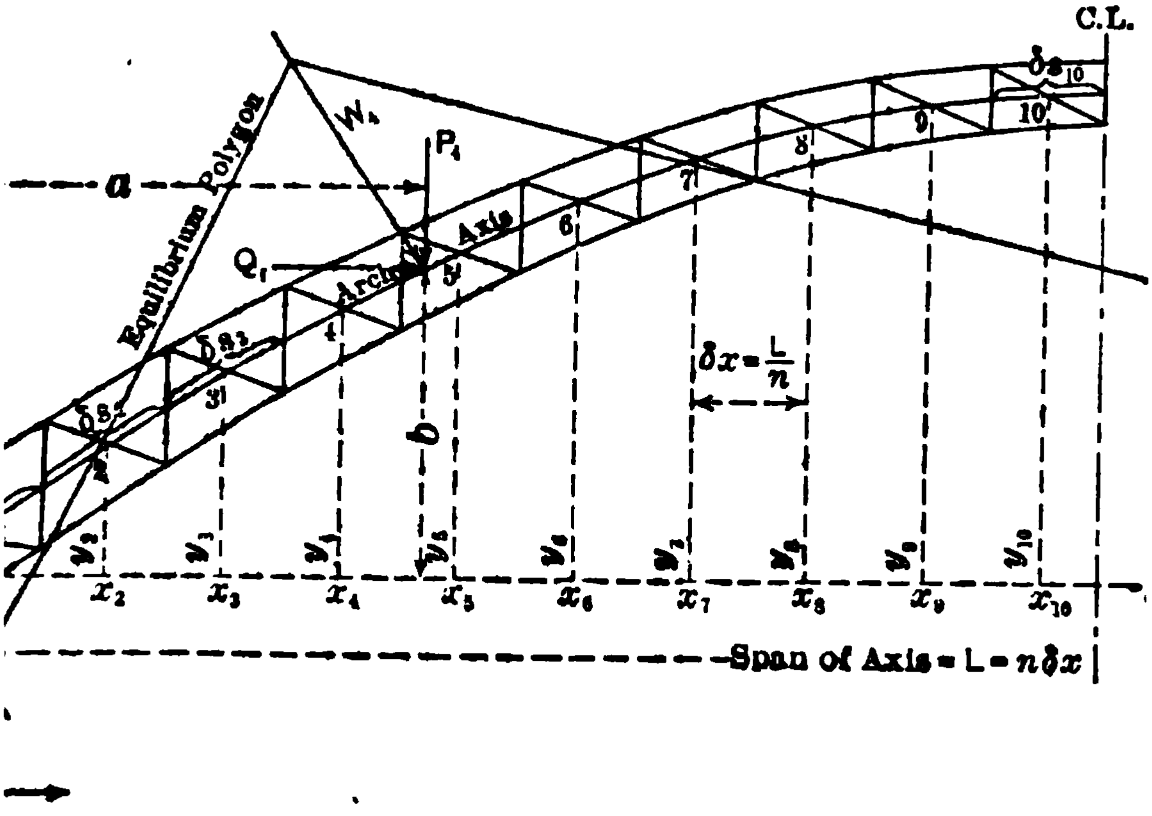

Fig. 63. Fixed Arch. Truss-diagram

points 1, 2, 3, etc., as shown by Fig. 63, which also indicates the e employed.

tion of H_1, V_1 and H_1y_1. The equilibrium-polygon for a single is shown in Fig. 63, in its true position with reference to the arch-ocates the point of application of H_1. The following formulas are pproximations for arches having a rise greater than one-eighth the

$$H_1 = \Sigma m_{xy} A'' \div \Sigma y A''$$

$$A'' = K\left\{y - \frac{\Sigma yK}{\Sigma K}\right\} \qquad K = \frac{\delta s}{EI}$$

$$\left.\begin{matrix} H_1 y_1 \\ H_2 y_2 \end{matrix}\right\} = H_1\frac{\Sigma yK}{\Sigma K} - \left\{\frac{\Sigma m_{xy}K}{\Sigma K} \pm \frac{\Sigma m_{xy}K(z-n)}{n^2\Sigma K - \Sigma z^2K}n\right\}$$

$$V_1 = \frac{H_1 y_2 - H_2 y_2}{L} + r_1 \qquad y_1 = \frac{H_1 y_1}{H_1}$$

l down from A when H_1y_1 is negative. Σ is the sum of quantities r each point on the arch-axis numbered 1, 2, 3, . . . n. For

$$\Sigma K = \left(\frac{\delta s}{EI}\right)_1 + \left(\frac{\delta s}{EI}\right)_2 + \left(\frac{\delta s}{EI}\right)_3 + \text{etc.}$$

I is the moment of inertia of the chords about an axis midway between th
The sections of the chords are to be taken on radial lines passing through point 1, 2, 3, etc. x and y are the coördinates the points 1, 2, 3, etc, in Fig. 63

$$x = z\frac{\delta x}{2} = z\frac{L}{2n}$$

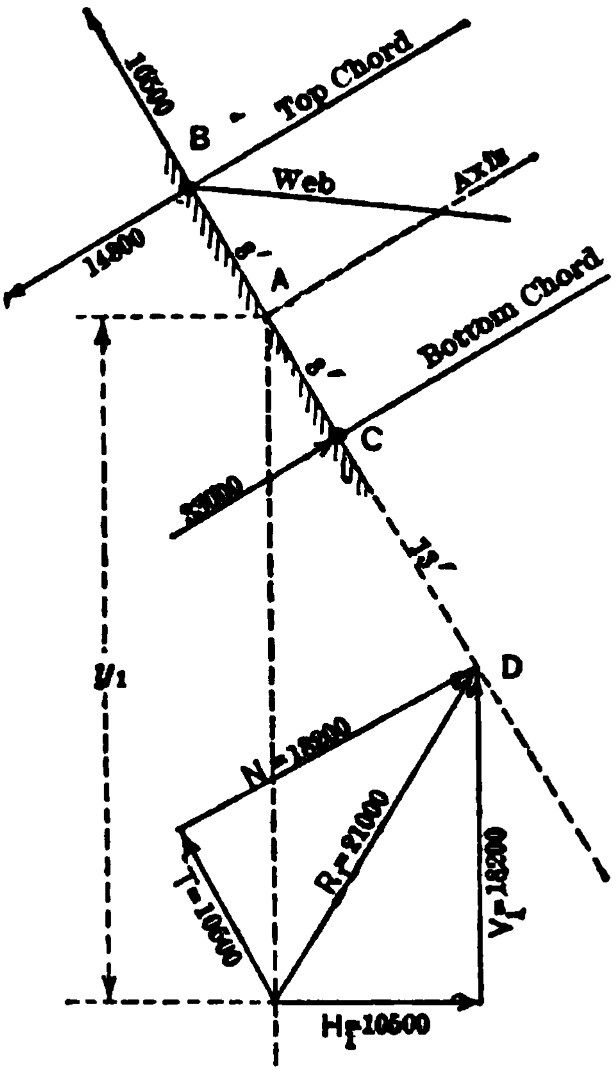

Fig. 64. Fixed Arch. Reactions

m_{xy} is the moment at the point on th arch-axis having the coördinates xy assum ing that the given loading is supported b the axis hinged at the right end and o rollers at the left end. r_1 is the reacti at the left support under the conditio specified for m_{xy}. In the above formul the only terms which depend upon th loading are those containing m_{xy} and r the others being constant for any give arch. While but one load has been use any number may be used by considerin m_{xy} and r_1 as the sum of the respecti quantities for each load.

Stresses. The STRESSES in the trus members can be found by the ordina graphical methods when H_1, V_1 and H are known. For example, assume th numerical values shown in Fig. 64. Th resultant of V_1 and H_1 is resolved int two components parallel and perpendi ular to the bottom-chord member a the support. Then T must act at th upper-chord joint as shown. The two reactions parallel to the bottom cho are found by moments. The stress-diagram can now be drawn beginning wi these forces and proceeding until the right support is reached.

Symmetrical Loading. When the loading is symmetrical, $H_1y_1 = H_2y_2$ an hence $V_1 = r_1$. Also

$$H_1y_1 = H_1\frac{\Sigma yK}{\Sigma K} - \frac{\Sigma m_{xy}K}{\Sigma K}$$

Changes of Temperature. For temperature-changes,

$$H_t = ct^\circ L + \Sigma yA''$$

$$H_1y_1 = H_2y_2 = H_t\frac{\Sigma yK}{\Sigma K}$$

$$y_1 = \frac{\Sigma yK}{\Sigma K} \qquad V_1 = 0$$

10. Arches with Solid Ribs

Arches with Solid Ribs. While this chapter considers TRUSSES only, may not be out of place to briefly consider ARCHES HAVING SOLID RIBS. T computations for V_1, H_1 and H_1y_1 remain unchanged, excepting that I now the moment of inertia of the radial section of the rib at points 1, 2, 3, etc.

esses. If x and y are the coördinates of any point on the gravity-rib, which should coincide with the arch-axis, the bending moment t is, for each load,

$$M_x = H_1 y_1 + V_1 x - H_1 y - P \overset{x>a}{(x-a)} - Q \overset{x>a}{(y-b)}$$

tive when y_1 is measured below A in Fig. 64.

$$S = \frac{M_x c}{I} + \frac{N_{xy}}{A}$$

he distance from the gravity-axis to the outermost fiber. For the REE-HINGED ARCHES, $H_1 y_1 = 0$.

ear. Let H_x be the algebraic sum of all the horizontal components of the section, V_x the algebraic sum of all the vertical components of the section and θ the angle which the radial section, upon which wanted, makes with the vertical. Then $T_x = V_x \cos\theta - H_x \sin\theta$.

ged Parabolic Arch. If the center line of the SOLID RIB is a PAR- $EI \cos\theta$ is a constant, the following simple formulas give the and H_1:

$$1 - k) - Q\frac{4f}{L}k(1-k)$$

$$\frac{L}{f} P[k(1-2k^2+k^3)] - Q\left\{1 - \frac{k}{2}[5(1-k-2k^2+4k^3) - 8k^4]\right\}$$

$$EI_0 et^\circ$$

$a + L$ (Fig. 63), f is the rise of the axis, P is the vertical load acting e horizontal load acting from left to right and I_0 is the moment of section of the rib at the crown.

abolic Arch. In like manner the following formulas apply for out hinges:

$$P(1-k)^2(1+2k) - \frac{12f}{L}Q(k-k^2)^2$$

$$\frac{15L}{4f}Pk^2(1-k)^2 - Q\left\{1 + k^2(-15 + 50k - 60k^2 + 24k^3)\right\}$$

$$\frac{L}{2}Pk(1-k)^2(5k-2) - fQ\left\{2k(1-k)^2(2 - 7k + 8k^2)\right\}$$

$$\frac{45}{4f}EI_0 et^\circ \qquad H_1 y_1 = \frac{15}{2f}EI_0 et^\circ$$

the factors containing k in the above formulas are given in tabular atise on Arches.*

ches, with solid ribs of constant cross-section and the center line rcle, may be considered by using formulas somewhat similar to r PARABOLIC ARCHES but very much longer and more complex. tables for their solution are given in the treatise on arches referred

on Arches, by Malverd A. Howe, John Wiley & Sons, Inc., New York.

11. Influence-Lines for Simple Beams and Trusses

An Influence-Line is a line showing the variation in any function at a section of a beam or for any member of a truss, caused by a single load movi across the span. For convenience the LOAD is usually considered as UNITY.

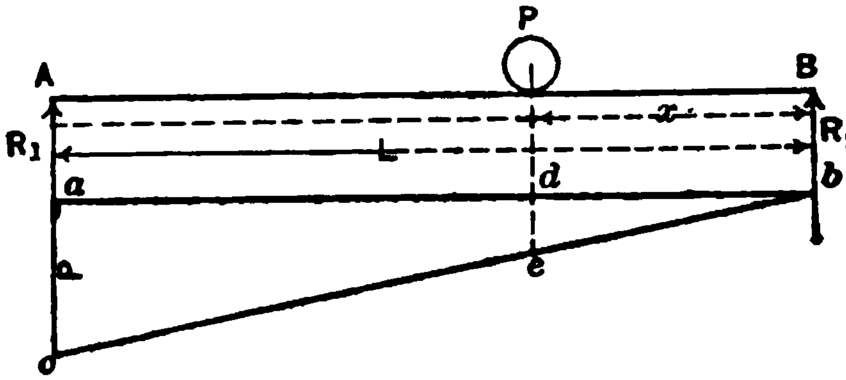

Fig. 65. Influence-lines. Reactions for Beams

Reaction for a Single Load. If the load P, Fig. 65, moves from A towa B, the left reaction, when P is distant x from B, is expressed algebraically $R_1 = Px \div L$, which is an equation of a straight line. If $x = 0$, $R_1 = 0$, i if $x = L$, $R_1 = P$. If we make $ac = P$ and draw the two straight lines ab and the ordinate de immediately below P is the value of R_1 for this position of If $ac =$ unity, then $R_1 = P\ (dc)$.

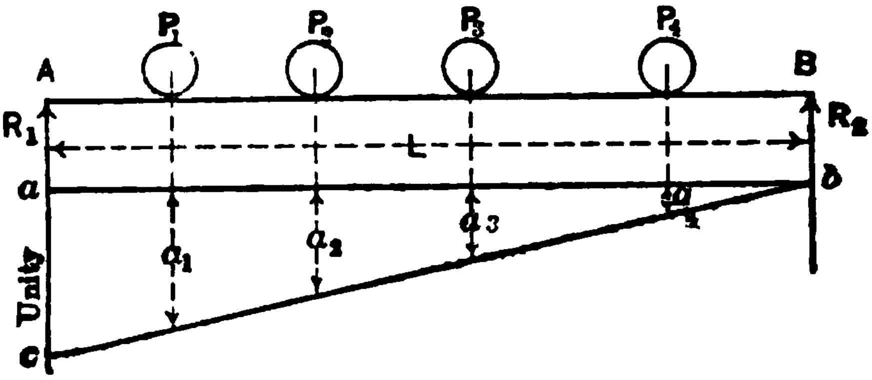

Fig. 66. Influence-lines. Reactions for Beams

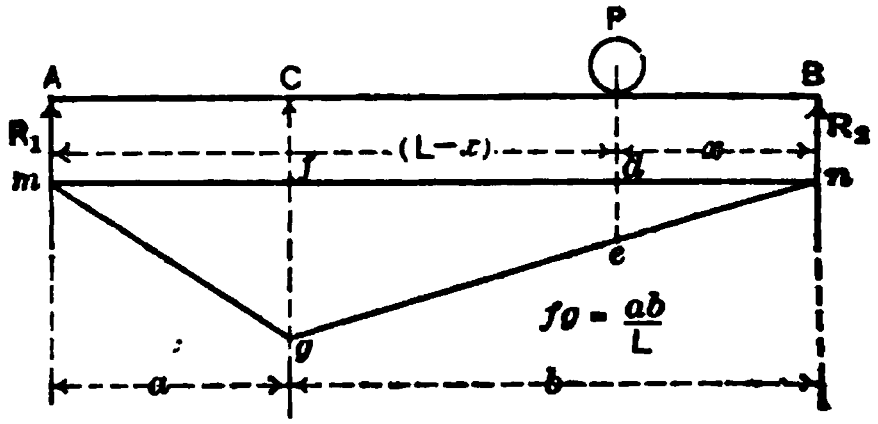

Fig. 67. Influence-lines. Moments for Beams

Reaction for More than One Load. The reaction for any numb concentrated loads can be found as shown in Fig. 66.

$$R_1 = P_1a_1 + P_2a_2 + P_3a_3 + P_4a_4$$

Bending Moment for a Single Load. The moment at C, Fig. 67, wh s on the right of C, is $M = R_1a = \dfrac{Pxa}{L}$. When the load is at C, $M = P$

at B, $M = 0$. For all positions of P upon the left of C, $M = R_2b$
$:)b$ —. When P is at A, $M = 0$, and when at C, $M = P\frac{(L-b)b}{L}$

. If in Fig. 67 the figure *mng* is drawn with $fg = \frac{(a)(b)}{L}$, then the
C for any load in any position is P (de).

Moment for Any Number of Concentrated Loads. The the point C for the loading shown in Fig. 68 is $M = P_1a_1 + P_2a_2$

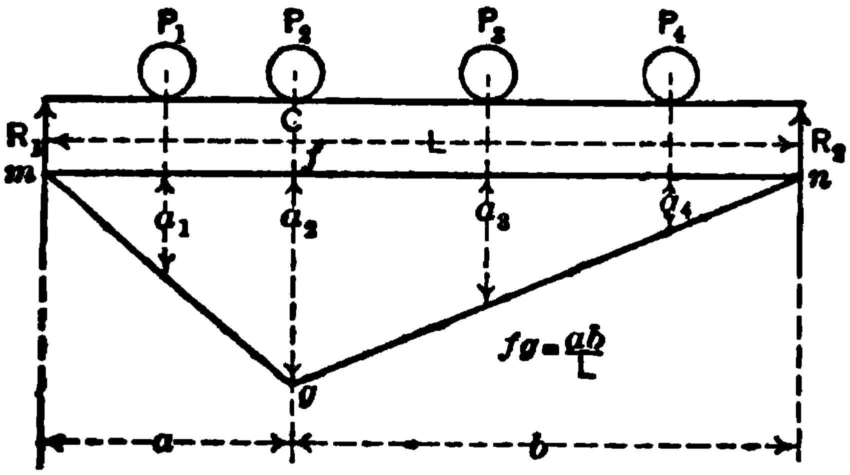

Fig. 68. Influence-lines. Moments for Beams

:4. This gives the moment at C for a given position of the loads, ot necessarily the GREATEST MOMENT which these loads may cause, r position may cause a greater moment. The greatest moment at when some concentration is at C. Let P be this concentration and

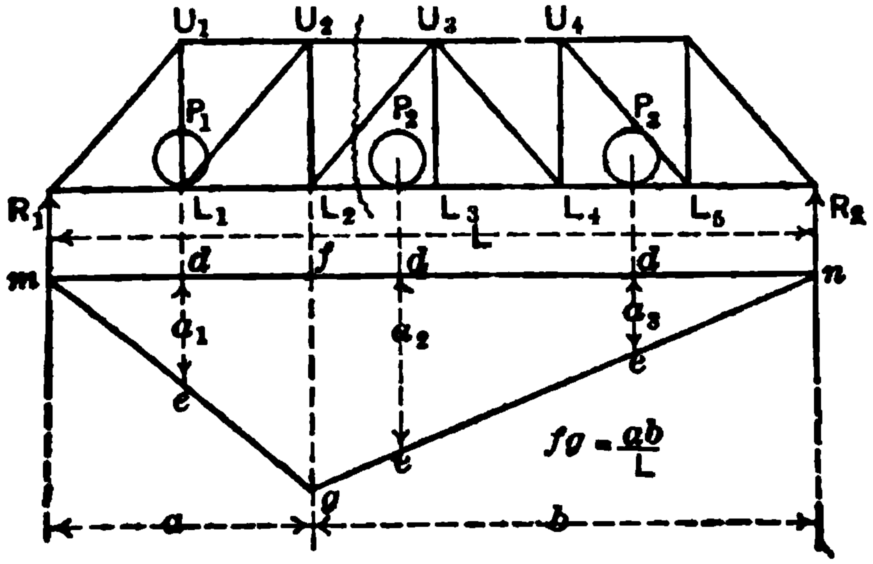

Fig. 69. Influence-lines. Moments for Trusses

›e divided into two parts, nP and mP so that $n + m = 1$, and n is ero and less than 1. The maximum moment at C will occur when

$$\frac{P_1 + P_2 + P_3 + P_4}{L} = \frac{P_1 + nP_2}{a}$$

n the beam where any given moving load causes the GREATEST ENT is so situated that the middle of the span is half-way between ter of gravity of the load. Since a concentration will always be a few trials will determine the proper concentration to use. For equal concentrated loads should be placed on the beam so that

the middle of the span is at the quarter-point between the concentrations. T MAXIMUM MOMENT falls under the concentration nearer the middle of the span

Chord-Member in Truss with One Set of Web-Members Vertical. Fig. 69 the top chord member U_2U_3 has its center of moments at L_2 and t bottom chord member L_1L_2 at U_2. The INFLUENCE-DIAGRAM for the mome at L_2 and U_2 is precisely the same as shown in Fig. 67. The moment produc by any load P is $P\ (de)$. As long as one set of web-members is vertical t INFLUENCE-DIAGRAM will be identical with that shown in Fig. 69, regardl of the inclination of the diagonals or the chord-members.

Chord-Members in Truss with Inclined Web-Members. The mome at points in the loaded chord, Fig. 70, have INFLUENCE-DIAGRAMS identical wi

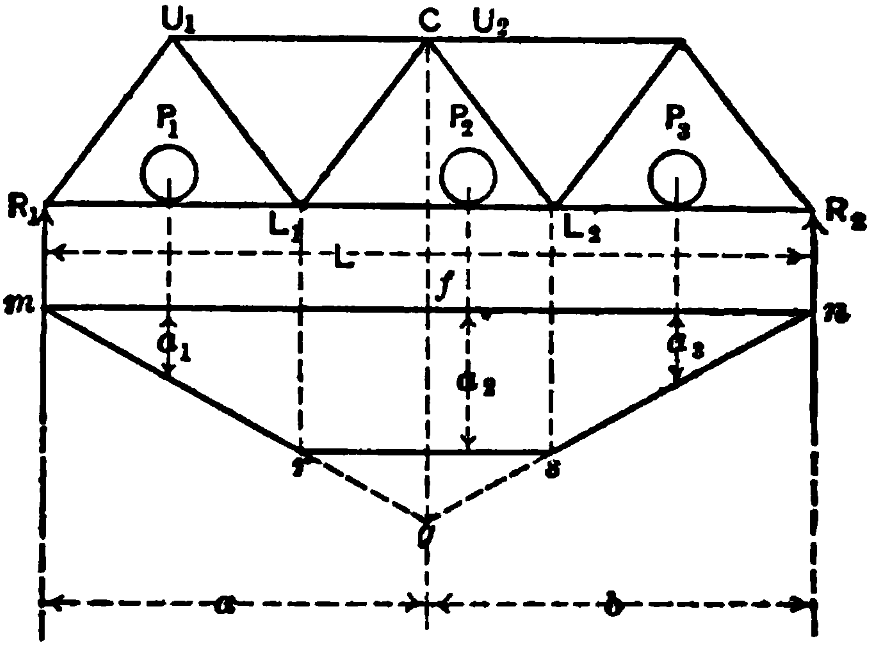

Fig. 70. Influence-lines. Moments for Trusses

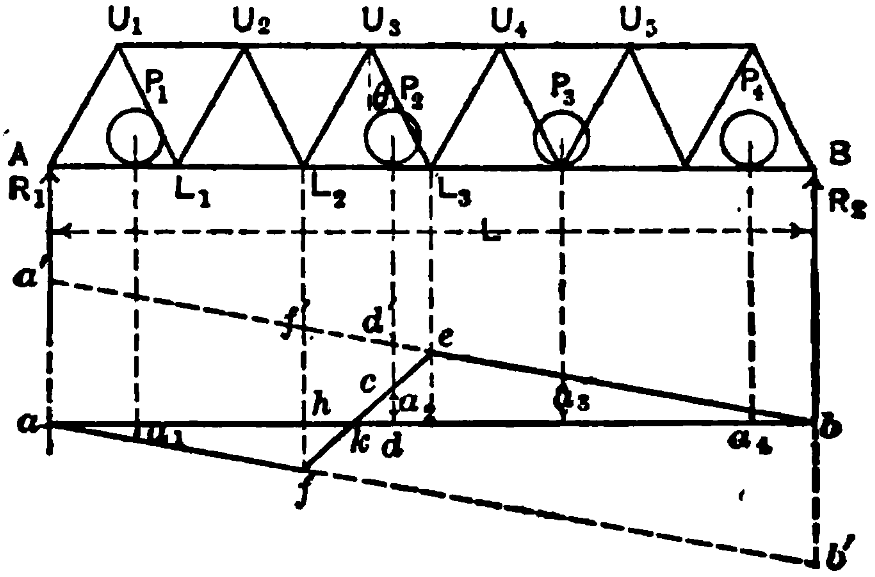

Fig. 71. Influence-lines. Shear for Trusses

that shown by Fig. 69. For the unloaded chord a slight modification must made. For example let U_2 be a center of moments, then if the loads were o beam, mgn would be the INFLUENCE-DIAGRAM (Fig. 70). For all loads on t left of L_1 and on the right of L_2 the diagram is correct and the moments at = P_1a_1 and P_3a_3. For loads between L_1 and L_2 draw the line rs. The mome at U_2 is P_2a_2.

Web-Members of Trusses with Parallel Chords. Fig. 71. The str in U_3L_3 equals the shear in the panel L_2L_3 multiplied by the secant of θ. T

DIAGRAM will be drawn for the shear. For any load between L_3 shear in this panel equals R_2; hence, with *ab* as a reference-line, *ba'* ENCE-LINE for R_2 and the shear is P_4a_4, P_3a_3, etc., until the point L_3 In like manner *af* is the INFLUENCE-LINE for R_1 and the shear for left of L_2 is P_1a_1. The shear for the loads P_2 between L_2 and L_3 amount of P_2 which is transferred to L_2. The INFLUENCE-DIAGRAM ions of P_2 on a span L_2L_3 is $ff'e$. The shear in this panel due to P_2 s P_2 $(d'c)$ or P_2a_2. A load at *k* produces no shear in the panel.

12. Secondary Stresses in Truss-Members *

y Stresses. In the determination of stresses in a truss it is med that they act along the GRAVITY-AXIS of each member; that axes of all members at any joint meet at a common point; that s are free to turn around this point, the joints being considered and that all loads, including the weights of the members, are he joints only. The stresses determined with these assumptions irect stresses, sometimes called PRIMARY STRESSES or MAIN STRESSES. tions made are not realized in practice and other stresses, called STRESSES, are induced. An eccentricity causing BENDING MOMENT e common case of the rivet-line not coinciding with the gravity-ngles connected with one leg only are used to resist direct stress. y-axes of members about a joint do not intersect at the same point nents are induced. The resistance of a joint to free angular move-truss deflects also induces bending moments. The weights of nd inclined members add slight BENDING-STRESSES to the direct ese members. At the supports there will be a RESISTANCE TO HORI-RMATION from temperature-changes and the deflection of the truss. of this resistance depends upon the coefficient of friction between the support, the vertical loads and the length of span. Members and imperfect workmanship are other causes of secondary stresses. the design and fabrication secondary stresses in ordinary roof-trusses ove causes need not be considered seriously. The main causes, secondary stresses are FAULTY DETAILS. The actual shearing-nes found in details is much more than the direct shearing-stress, CCENTRICITY IN THE LINES OF STRESS-ACTION. Eccentric riveted may not be wholly avoided but they should be reduced to a mini-history of bridge and building-failures is mostly a story of faulty tructure has seldom given way for lack of strength in the main ut if the strength of a structure is measured by the strength of art, it can be only as strong as the weakest detail. Because of ions that induce large secondary stresses, insufficient lacing of nembers and careless grouping of rivets, have all invited disaster. nce of the detailer's work is often underrated. What is usually e DESIGNING of a structure may be comparatively easy while the ay be difficult. A well-designed structure may be spoiled by . The detailer should be a designer, that is, a designer of details, ne time the designer should be thoroughly familiar with detailing.

* From Notes by Robins Fleming.

CHAPTER XXVIII

DESIGN AND CONSTRUCTION OF ROOF-TRUSSES

By

MALVERD A. HOWE

PROFESSOR EMERITUS OF CIVIL ENGINEERING, ROSE POLYTECHNIC INSTITUT

1. Design of Wooden Trusses

Proportioning the Members. In Chapter XXVII it has been shown h the STRESSES in the members of a truss, supporting known LOADS, may be fou The next step is to PROPORTION THE MEMBERS for the stresses which they h to resist. The methods employed and the ALLOWABLE UNIT STRESSES are giv in detail in Chapters XI to XVI, inclusive. For example, tension-members considered on pages 385 to 400; steel strut-beams and tie-beams on pages 5 and 572; and wooden strut-beams and tie-beams on page 633. As a matt of convenience the UNIT STRESSES used in this chapter are given in the followi table in a condensed form. White pine is here used for the wooden trusses.

Table I. Allowable Unit Stresses Used in Truss-Design *

Material	Kind of stress	Safe unit stre lb per sq in
White pine.........	Tension with the grain....................	700
"	Tension across the grain..................	50
"	Compression on end-fibers................	1 100
"	Compression across the grain..............	200
"	Compression across the grain, round pins..	200

"	Beams in shear............................	10 000

* See also, the tables on pages 376, 412, 449, 454, 557, 647 and 1 200. These must modified, when necessary, to comply with building laws. White pine is used for t examples in this chapter because of the difficulties in making the joints owing to the r ative softness of the wood. If one can design a truss in white pine he will have no troub with the design of trusses constructed with other kinds of wood.

† See, also, Table I, page 449, and Table XVI, page 647.

‡ The Borough of Manhattan, New York, Building Code (1917), gives 1 200 for t value. Other values are about the same as in the table.

Inclined Surfaces of Wood. The normal intensity of the stress on inclin surfaces may be found from the empirical formula

$$r = q + (p - q)(\theta/90)^2$$

juals the permissible normal unit stress on this inclined surface, q the fibers, p that on the end of the fibers and θ the angle the inclined kes with the direction of the grain. For white pine this gives

$$r = 200 + \theta^2/9$$

Pins on End-Fibers.* For all practical purposes the permissible may be taken as the mean of p and q; or, for white pine

$$\tfrac{1}{2}(p+q) = 650 \text{ lb per sq in}$$

Columns over Fifteen Diameters Long. The formula † used in r and considered amply conservative by many engineers is the proved by the American Railway Engineering and Maintenance of ation in 1907. For white pine this formula is

$$S_1 = S\,(1 - l/60\,d) = 1100\,(1 - l/60\,d)$$

the permissible unit stress, S = the permissible compression on the = the length of the column in inches and d the least dimension ot ction of the column in inches.

lumns. For the shapes used in roof-trusses, the formula advocated wler in his specifications for roof-trusses is used in this chapter:

$$S_1 = 12\,500 - 500\,l/r$$

he permissible unit stress, l = the length of the column in feet, and radius of gyration of the cross-section of the column.

. The truss shown in Fig. 1, which is the queen truss shown in 53 and 54 in Chapter XXVII, is considered for this example. The n in the following table are used. The members RR are wrought-rods, not upset at the ends; and all other members are of white of the members in this truss is subject to transverse stress, so n and compression only, have to be considered:

. **Stresses and Dimensions for the Truss Shown in Figure 1**

er	Stress in pounds	Dimensions
....	+21 250	6 by 6-in white pine
....	+18 900	6 by 6-in white pine
....	+13 200	6 by 6-in white pine
....	+ 6 450	4 by 6-in white pine
....	+ 5 100	4 by 6-in white pine
....	−17 150	6 by 8-in white pine or Three 2 by 8-in pieces with ¾-in bolts, 2 ft on centers
....	−12 750	
....	− 9 100	One 1¼-in round rod

ls, **Fig. 1.** The tension in each rod is 9 100 lb. If the permis-2 000 lb, the section-area of each rod is 9 100 ÷ 12 000 = 0.76 sq in. f a 1⅛-in rod is 0.694 sq in; and of a 1¼-in rod, 0.893 sq in. The ld answer but the 1¼-in rod is preferred.

same unit stresses are used for flat and curved surfaces, Tables VII and to 431, of Chapter XII may be used.
rmulas and Tables based upon them, see Chapter XIV, pages 449 to 452.

Rafters, Fig. 1. The stress in the rafter at A is 21 250 lb and at B 18 900
but as it will be made of one piece, the size is governed by the greater str
The unsupported length is about 9 ft, and assuming the least dimension of
piece to be 6 in, $S_1 = 1\,100\left(1 - \frac{9 \times 12}{60 \times 6}\right) = 770$ lb per sq in. 21 250/77
27.6 sq in = the area of cross-section required, which is less than that of a 6 by
piece. A 6 by 6-in timber is actually 5½ by 5½-in, with a cross-sectional are
30.25 sq in, a little in excess of the area required. In general the NOMINAL
STANDARD sizes of timbers differ by about one-half an inch in each cross-dimens

Fig. 1. Queen Truss. (See, also, Figs. 4A, 10, 13 and 16 and Chapter XXVII,
3, 12, 53 and 54)

Member C, Fig. 1. The stress in this member is 13 200 lb and its unsuppo
length, 12 ft. In this case $l/d = 24$, when $d = 6$ in; $S_1 = 660$ lb per sq in.
required section-area is 13 200/660 = 20 sq in, and hence a 6 by 6-in timbe
used. The top-chord should have one dimension constant in order to facili
the making of good connections at the joints.

Braces, Fig. 1. The stress in the brace D is 6 450 lb and its unsuppor
length about 9 ft. A 4 by 6-in timber is first tried. Here $l/d = 27$ and $S_1 =$
lb per sq in. The required area, therefore, is 10.7 sq in and a 4 by 4-in tim
answers the purpose; but for additional stiffness and convenience in making
nections, a 4 by 6-in piece is used. Each brace, E, has a stress of 5 100 lb a
total length of 17 ft. If the braces are bolted where they cross the unsuppo
length may be taken as 8½ ft. It is evident that a 4 by 6-in piece is ample
each brace.

Bottom Chord, or Tie-Beam, Fig. 1. The maximum tension in the bott
chord is 17 150 lb in N. The permissible unit stress is 700 lb per sq in; he
the net section-area required is 17 150/700 = 24.5 sq in. A 2 by 12-in plan
continuous from end to end of the truss and without holes and notches, will t
care of the stress alone but will not permit of proper connections. A 6 by
piece is selected, but it may be necessary to substitute for it a 6 by 8-in p
when the connections are made and it is spliced in the middle. If the mem
is built up of planks, three 2 by 8-in pieces are required; and they must

bolted together by a pair of bolts every 2 ft of their length. If 24-lengths are used, the joints of the strands will be about 10 ft apart.

ı. For this example the truss illustrated in Fig. 2, which is the s shown in Figs. 4 and 24, Chapter XXVII, is considered. The s for dead load, wind and snow were found in Chapter XXVII and the following table. The rafters and the bottom chord support

. Scissors Truss. (See, also, Chapter XXVII, Figs. 4 and 24)

the joints and consequently must resist CROSS-BENDING stresses ECT STRESSES. The load on each piece is given in the table under ISVERSE.

Stresses and Dimensions for the Truss Shown in Figure 2

r	Stress, lb	Transverse load, lb	Dimensions, white pine
....	+8 000	1 000	Two 2 by 8-in planks
....	+6 600	1 320	Two 2 by 8-in planks
....	+1 890	....	One 2 by 10-in plank
....	+ 750	....	One 2 by 10-in plank
....	−4 350	....	Two 1 by 8-in planks
....	−2 530	....	Two 1 by 8-in planks
....	−1 875	470	One 2 by 10-in plank
....	−5 400	384	One 2 by 10-in plank
....	−1 875	....	One 2 by 10-in plank

g. 2. The piece *B* rather than the piece *A* is considered, as it is onger. The total vertical load on the piece acting as a beam is e horizontal span is about 8 ft. The bending moment at the center

is $\frac{1}{8}(1\,320 \times 8 \times 12) = 15\,840$ in-lb. If the depth of the piece is assumed be 8 in, the proper thickness is found from the equation, $15\,840 = \frac{1}{6} Sb$ $\frac{1}{6}(700 \times 8 \times 8 \times b)$, or $b = 2.12$ in. This neglects the component of the v tical load parallel to the rafter. Considering now the direct compression 6 600 lb and remembering that the sheathing is nailed to the rafter, the le dimension d of the piece is its depth, which may be taken the same as t used for the piece resisting the TRANSVERSE STRESS. The unsupported len of the piece is about 12 ft. Then $l/d = 18$, $S_1 = 770$ lb per sq in and the requi area of cross-section is $6\,600/770 = 8.6$ sq in. As the depth is 8 in, the thicknes about 1.1 in. Combining the two pieces, the total thickness is $2.12 + 1.1 = 3$ in, and a piece having the nominal size of 4 by 8 in is required. Since sheathing is nailed to the rafters, two 2 by 8-in planks may be used without creasing the stiffness of the member. While the above method of designin piece subject to TWO KINDS OF STRESS is not correct for all conditions wh occur in practice, the results are on the safe side, and the method has the vantage of being easily applied.

Member S, Fig. 2. Considering the transverse load first, the bending mom at the middle is found to be $\frac{1}{8}(470 \times 15.5 \times 12) = 10\,930$ in-lb. If the depth assumed to be 10 in, the required thickness, found from the equation 10 $= \frac{1}{6}(700 \times 10 \times 10 \times b)$, is 0.94 in; or, a board 1 by 10 in in cross-sectional a will carry the transverse load if prevented from twisting sidewise, which it ha tendency to do in this case where the ceiling is attached directly to the memb The side-stiffness will be further increased when the additional material resisting the tension is in place. The net area for the direct tension of 1 87 is 2.68 sq in, which requires a board 10 in wide and only a trifle over $\frac{1}{4}$ in th The total thickness becomes $0.94 + 0.27 = 1.21$ in, and it will therefore be n essary to use a 2 by 10-in plank.

Member E, Fig. 2. This is in compression, but the stress is quite sm being only 750 lb. The possible extension of the 2 by 10-in piece used for S next considered, to find if it can be extended and used here. The unsuppor length is about 6 ft, and the least dimension 2 in; hence $l/d = 36$, $S_1 = 44$ per sq in and the required area of the cross-section becomes less than 2 sq The 2 by 10-in piece is therefore ample.

Members T and T_1, Fig. 2. Inspection shows that a 2 by 10-in plan quite sufficient for these pieces.

Member D, Fig. 2. The unsupported length is about 7 ft. Then, for d in, $l/d = 42$, $S_1 = 330$ lb per sq in and the required section-area is $1\,890/33$ 5.73 sq in. A piece 2 by 10 in is more than sufficient; but as this size allow a simple prolongation of the pieces T and T_1, a piece of this dimension is us

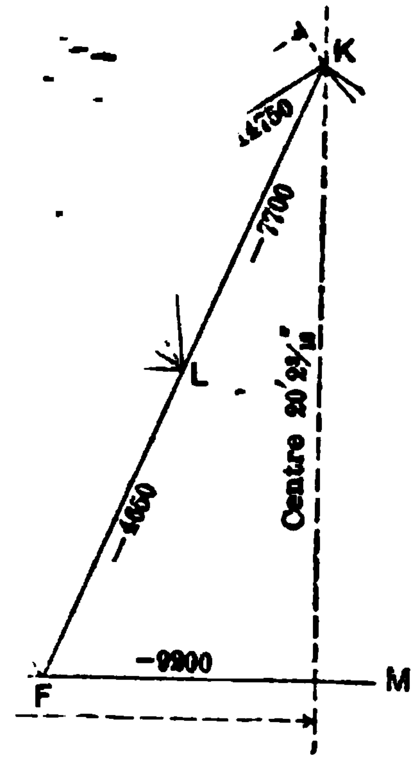
Members F and H, Fig. 2. For the piece F a net area of $4\,350/700 =$ sq in is required; or a board 1 by 8 in in cross-section may be used. For c venience in construction, two 1 by 8-in boards are chosen. It is evident that same arrangement can be made for the piece H.

Caution. Since this truss is a SCISSORS TRUSS, the horizontal deflection the supports should be determined, and, if this is an appreciable quantity, members as designed above, should be increased in size or their lengths chan in framing; this is so that the span, after the truss is loaded and the deflec has taken place, becomes the distance between the supports. This is discus in Chapter XXVII, pages 1085 to 1087.

Example 3. For this example the HOWE TRUSS shown in Fig. 3 is conside The vertical load is assumed to be $46\frac{1}{2}$ lb per sq ft on the top-chord and per sq ft on the bottom-chord. For trusses spaced about 15 ft 8 in on cent

... is 2½ by 2 by ¼ in; and while ⅝-in ... rivets, which are the largest that ... wooden trusses, it is economical ... the same straight line, but

...ions of a truss ...ght and con-



... with Stresses

...ny of the members. For conven-
...mbers and final sections are arranged

... or the Half-Truss Shown in Figure 5

	Net area required, sq in	Make-up of member
	1.06	Two 2½ by 2 by ¼-in angles Net area = 1.70 sq in
..	....	
..	....	
...	....	
....	....	
.....	....	
72	....	Two 2½ by 2½ by ¼-in angles, and one 10 by ¼-in plate
144	....	Two 2½ by 2 by ¼-in angles
72	....	

This member has the maximum stress of the bottom- ...e used up to the joint F and possibly for the entire length ...t area required is 16 900/16 000 = 1.06 sq in, or the net ...ngle is 0.53 sq in. One leg of the angle is riveted to the ...in rivets which is assumed to cut out a section ... the

chord 10 by 12 in. A single piece of this size, nearly 50 ft long, is difficul obtain; so at least one splice is necessary. If planks are substituted it requ six 2 by 12-in pieces to give an equivalent area.

Inclined End-Post, Fig. 8. The stress in this post is 33 450 lb and its supported length about 9.75 ft. An 8 by 10-in piece is tried first, the dimension being the same as one dimension of the chords. Then $l/d = 14$ $S_1 = 825$ lb per sq in and the required area of cross-section becomes 33 450/82 40.54 sq in, which is about one-half the cross-sectional area of an 8 by 10-in pi If $d = 6$ in, there results $l/d = 19.50$, $S_1 = 740$ lb per sq in and the required = 45.2 sq in, which is a much smaller cross-sectional area than that of a 6 10-in timber.

Intermediate Diagonals, Fig. 8. For the first diagonal a 6 by 6-in piec tried. The required section-area is 19 630/740 = 26.5 sq in, which is well wi the section-area of a 6 by 6-in timber. A 4 by 4-in timber could be used for next brace, but it is better to use either a 6 by 6-in timber or one 4 by 6 i

Purlins, Figs. 1 and 4A. While the stresses given for the members of truss shown in Fig. 1 are based upon a vertical loading covering the effec dead load, snow-load and wind-load, the w load is separated from the others in orde illustrate the method to be followed in de ing a purlin when the plane of the load is parallel to one of its sides. The trusses of type illustrated in Fig. 1, are 15 ft on cen This distance, therefore, is the span of purlin. The purlin at joint 2, Fig. 1, h vertical loading of 4 500 lb and a wind-l acting normal to the roof, of 2 000 lb. inclined loading, resolved parallel to b a Fig 4A, and combined with the vertical l gives for the total, parallel to d, 4 500 + 1 = 5 900 lb; and for that parallel to b, 1 lb. If then, loads are assumed to act thr the center of gravity of the purlin-section,

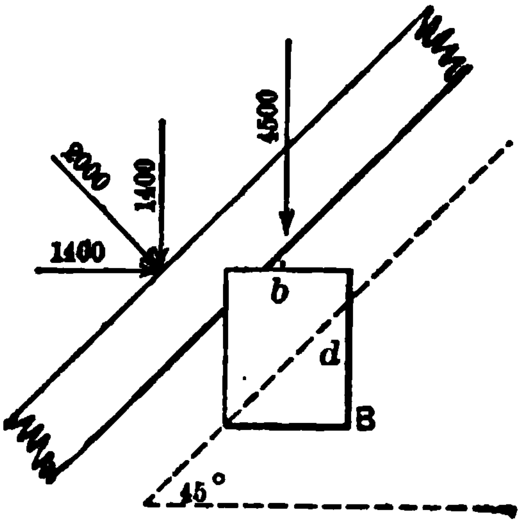


Fig. 4A. Purlin-design for Joint 2 of Truss Shown in Fig. 1

produce both tension in the fiber at B and compression diagonally opposit The bending moment at the middle of the purlin due to the vertical load (5 900 × 15 × 12) = 132 750 in-lb; and that due to the horizontal load (1 400 × 15 × 12) = 31 500 in-lb. It is assumed that $b = 8$ in and $d = 1$ Then the fiber-stress at B, due to the first moment is

$$S' = 6 \times 132\,750/bd^2 = 996 \text{ lb per sq in}$$

The fiber-stress at B, produced by the second moment is

$$S'' = 6 \times 31\,500/b^2d = 295 \text{ lb per sq in}$$

The total fiber-stress is 996 + 295 = 1 291 lb per sq in. This is 91 lb in e of the permissible fiber-stress in the most conservative practice and in som building laws for white oak. If a 10 by 10-in timber is used the fiber- is 986 lb per sq. in, and if the piece is 10 by 12-in, the fiber-stress become lb per sq in.

2. Design of Steel Trusses

General Considerations. The members of the ordinary STEEL TRUSSES are composed of two rolled ANGLES placed back to back and a joints each piece is connected to GUSSET-PLATES by RIVETS. The size o

mallest angle permissible in good practice is 2½ by 2 by ¼ in; and while ⅝-in vets are often used, it is better to use ¾-in rivets, which are the largest that in be used in a 2½-in leg of an angle. As in wooden trusses, it is economical) use the same sizes for all members which are in the same straight line, but is is not always done.

Example 4. Fig. 5 shows a FAN TRUSS of the form and dimensions of a truss ed for supporting the roof of a machine-shop. The loading is light and con-

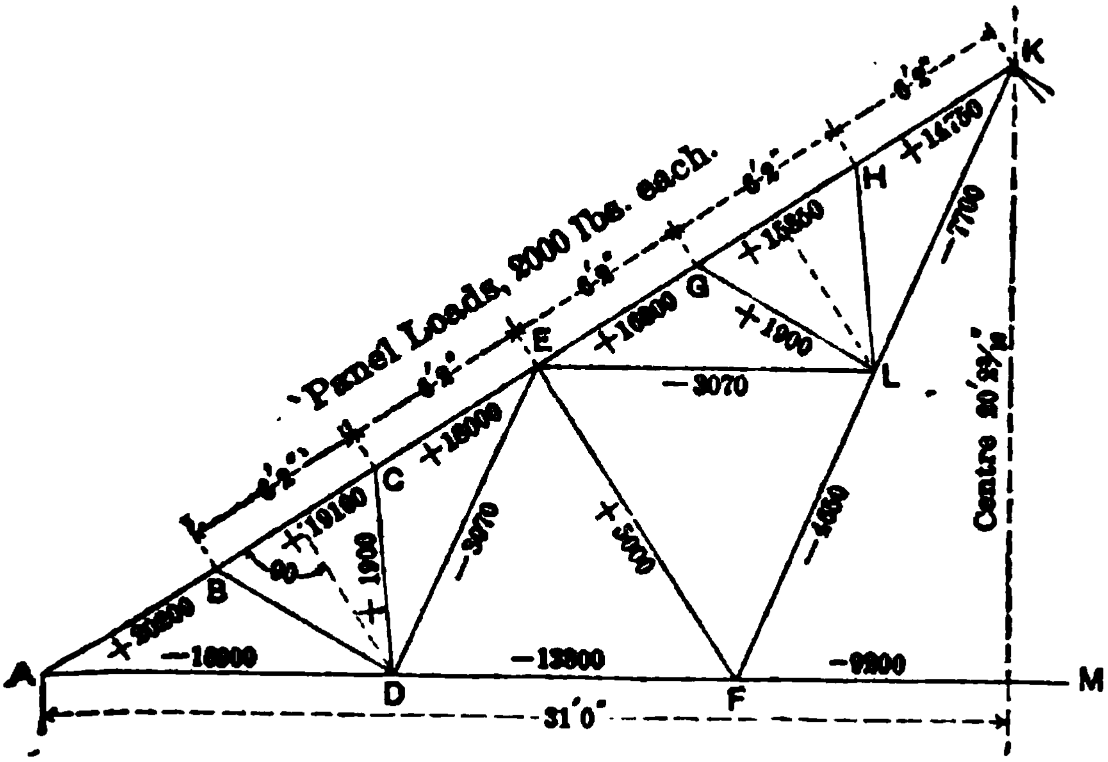

Fig. 5. Fan-truss Diagram with Stresses

quently the stresses are quite small in many of the members. For convenie ce the stresses, lengths of compression-members and final sections are arranged tabular form.

Member AD, Fig. 5. This member has the maximum stress of the bottom-rd and its size will be used up to the joint F and possibly for the entire length he chord. The net area required is 16 900/16 000 = 1.06 sq in, or the net ion-area of one angle is 0.53 sq in. One leg of the angle is riveted to the et-plate with ¾-in rivets which is assumed to cut out a section ⅞ in by the

thickness of the angle. From Table XI, page 365, we find that a $2\frac{1}{2}$ by 2
$\frac{1}{4}$-in angle has an area of 1.06 sq in. The area to be deducted on account
one rivet-hole is $\frac{7}{8}\times\frac{1}{4} = \frac{7}{32} = 0.22$ sq in. This leaves for the net area of t
angle $1.06 - 0.22 = 0.84$ sq in, which is well above the required area. As th
is the smallest angle which can be used and as all the other tension-membe
have less stress than AD, the tension-members will be made uniform throug
out. With the exception of FK, many designers would use but one angle f
the web-members. While the net area is ample for the stresses, yet it is po
practice, as one angle produces a ONE-SIDED PULL on the gusset-plates.

Member AB, Fig. 5. This piece has the maximum stress of the top-chor
a compression of 20 200 lb and a transverse load of 2 000 lb. The COMBINI
EFFECT OF THE TWO LOADINGS in this case must be determined in a mann
quite different from that followed for wooden construction. The maximu
fiber-stress must not exceed that found from some column-formula as, f
example, $S_1 = 12\,500 - 500\ l/r$. The maximum fibe
stress S may be found, approximately, from the expre
sion $S = P/A + Mc/I$. In this equation, P is t
direct compression, which is 20 200 lb in this cas
A the area of the section of the piece, I the mome
of inertia of this section, c the distance of the oute
most fiber of the section which is in compression fro
its gravity-axis and M the maximum bending mome
produced by the tranverse load. The PRINCIPAL AX
of the section must lie in the plane of the transver
loading, if the above formula is used. For sy
metrical sections, as two angles back to back, an
beam, or a channel, the principal axes are AXES
SYMMETRY, and the values of I and c are readi
found from the properties of rolled shapes tabula
in Chapter X. The first trial-section is that sho
in Fig. 6, consisting of two $2\frac{1}{2}$ by $2\frac{1}{2}$ by $\frac{1}{4}$-in angl
and one 10 by $\frac{1}{4}$-in plate. To find the moment
inertia, I, and the radius of gyration, r, the center of gravity of the section
found first. The distance X of the center of gravity from AB (Fig. 6) is fou
from Equation (2), page 295,

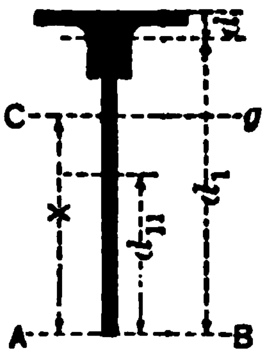

Fig. 6. Section through Rafter-member of Truss Shown in Fig. 5. (Axis at d_1 from AB, through c. g. of angles; axis at Cg, through c. g. of sections; axis at d_{11} from AB, through c. g. of plate.)

$$X = \frac{\text{area of plate} \times d_{11} + \text{area of angles} \times d_1}{\text{area of entire section}}$$

From the properties of angles, Table XII, page 367, the distance from the ba
to the center of gravity of the angle is $d = 0.72$ in. $I = 0.7$ and the area of
two angles $= 2.38$ sq in. The plate does not usually extend to the back of
angles, a clearance of from $\frac{1}{8}$ to $\frac{1}{4}$ in being allowed. A clearance of $\frac{1}{4}$ in
assumed.

Then, $\quad d_1 = 10.25 - 0.72 = 9.53$ in, and $d_{11} = 5$ in

Hence, $\quad X = \dfrac{2.5 \times 5 + 2.38 \times 9.53}{2.50 + 2.38} = 7.21$ in

The value of the moment of inertia I, about Cg as an axis, is found as foll
(Chapter X):

For the plate (page 335), $\quad \dfrac{th^3}{12} = \dfrac{0.25 \times 10^3}{12} = 20.80$

Eq. (3) (page 338), $\quad A\,(X - d_{11})^2 = 2.5\,(2.21)^2 = 12.21$

) angles (page 367) $2 \times 0.70 = 1.40$
ge 338), $A(d_1 - X)^2 = 2.38\,(2.32)^2 = 12.81$
ire section, $I = 47.22$

section, $I = Ar^2$ or $r = \sqrt{I/A}$, hence for this section $r = \sqrt{47.22/4.88}$ (See Equation (2), page 333.) The distance to the outermost fiber ion from the axis Cg is 3.04 in $= c$. There is now sufficient data to e actual fiber-stresses due to the loading and also the permissible bending moment produced by the transverse load is

$$M = \tfrac{1}{8}(2\,000 \times 6.16 \times 12) = 18\,480 \text{ in lb}$$
$$S = 20\,200/4.88 + (18\,480 \times 3.04)/47.22 = 5\,330 \text{ lb per sq in}$$
$$S_1 = 12\,500 - 500 \times 6.16/3.11 = 11\,510 \text{ lb per sq in}$$

s that the actual fiber-stress is very much smaller than the allowss, but as we have used minimum-size angles and a minimum thickplate, the only way to reduce this section is to use a smaller plate. asible because of the requirements for making proper connections
The above analysis assumes that the member is prevented from vise by the roof-covering. If such is not the case, r will have to d for a vertical axis through the center of gravity of the section. the moment of inertia,

$$bt^3/12 = (10 \times 0.25^3)/12 = 0.013$$
s, $$2 \times 0.70 = 1.400$$
$$2.38\,(0.72 + 0.125)^2 = 1.699$$
section, $I = 3.112$

$$r = \sqrt{3.112/4.88} = 0.6377 \text{ in}$$
$$S_1 = 12\,500 - 500 \times 6.16/0.6377 = 7\,670 \text{ lb per sq in}$$

less than the value of S_1, and hence this sections fulfills all the considering the unsupported length verticallv and sidewise as

, Fig. 5. Taking two $2\tfrac{1}{2}$ by 2 by $\tfrac{1}{4}$-in angles with the $2\tfrac{1}{2}$-in ack, the least value of $r = 0.78$ in (Table XVI, page 371).

$$S_1 = 12\,500 - 500 \times 12/0.78 = 4\,810 \text{ lb per sq in}$$
$$5\,000 \div 4\,810 = 1.04 \text{ sq in, required.}$$

he two angles used is $2 \times 1.06 = 2.12$ sq in (Table XVI, page 371).

Fig. 5. The stress in this member is very small and one angle lfill the requirements. For one angle, $2\tfrac{1}{2}$ by 2 by $\tfrac{1}{4}$ in, the least ole XI, page 365) and $S_1 = 5\,300$ lb per sq in, indicating that this rge excess of strength. As pointed out above, it is better to use

Ratio. The best specifications limit the ratio of the least dimenpported length of a compression-member to 50, unless the allowas given by the column-formula is decreased. The member EF nd about 144 in long, so that its length is 57.6 times its least there is a great excess of area, the actual unit stress is much by the formula.

The compression-members made up of two angles and designed the preceding paragraphs, have been considered as if acting as is clear that the various parts must be so fastened together that ce will buckle. If l is the unsupported length of the member

as a whole, r the corresponding least radius of gyration, r' the least radi
gyration for any part and l' the unsupported length of the part, or the dis
between stay-rivets, there is the following relation:

$$l'/r' = l/r \text{ or } l' = lr'/r$$

For the member *EF* $l' = 144 \times 0.42/0.78 = 78$ in.
Practice reduces this to 2 or 3 ft.

Tension-Members, also, should be riveted together in a similar mann
make the parts pull together.

Example 5. The next truss considered is the FINK TRUSS shown in F
in which two angles are used for all members and ¾-in rivets at the co
tions.

Member *AC*, Fig. 7. For a unit stress of 16 000 lb per sq in, the net
required is 21 800/16 000 = 1.36 sq in. Two 2½ by 2½ by ¼-in angles h
section-area of 2.38 sq in (Table XII, page 367). Deducting 2 (⅞ × ¼) =
sq in, the net section becomes 1.94 sq in, while the required area is 1.36

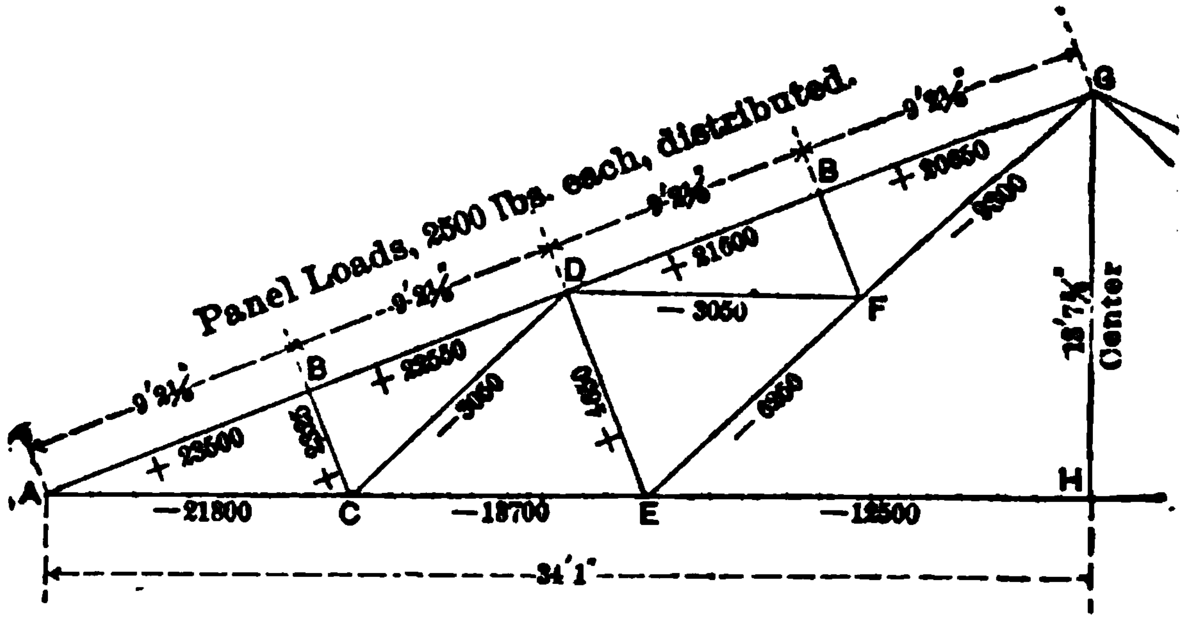

Fig. 7. Fink Truss. (See, also, Figs. 22, 22A, 22B, 22C, and 22D)

Members *CE* and *EH*, Fig. 7, are composed of angles of the same size.

Members *CD*, *DF*, *EF* and *FG*, Fig. 7, are made of two 2½ by 2 by
angles with a net area of 2.12 sq in. This greatly exceeds the required a

Members *BC*, *BF* and *DE*, Fig. 7. From the preceding example it is ev
that a pair of minimum-size angles will be quite sufficient. Two 2½ by
¼-in angles, having a section-area of 2.12 sq in, are used.

Member *AB*, Fig. 7. For this member in which there is a direct com
sion of 23 500 lb and a transverse stress due to a load of 2 500 lb, a prelim
trial is made with two 5 by 3½ by ⅜-in angles, with the 5-in legs back to bac
separated by a ¼-in gusset-plate. The moment of inertia about an axis p
through the center of gravity of the two angles and parallel to the short
is (Table XI, page 363) 7.78* and the corresponding radius of gyration
in. About a vertical axis the radius of gyration is (Table XVI, page
1.42 in, which is the least radius to be used in the column-formula.

* It will be noticed that some values given for the properties and the sizes of angl
in this example differ slightly from those given in the tables referred to, as the sectio
I, r, x, etc. This changes the result very slightly and is due to variations in the d
figures of values in different editions of manufacturers' handbooks. Editor-in-c

oduced by the 2 500-lb load at the center of the member is ⅛ × 12) = 34 500 in-lb. The section-area of the two angles is (page n.

$= [23\,500/6.10] + [(34\,500 \times 1.61)/7.78] = 10\,990$ lb per sq in
$= 12\,500 - (500 \times 9.2)/1.42 = 9\,260$ lb per sq in

ss than S, it is seen that the angles selected are a little too light. sing angles of greater thickness it will be better to select a larger 6 by 3½ by ⅜-in angles are used (page 363)

$= [23\,500/6.86] + [34\,500 \times 2.04)/12.86] = 8\,890$ lb per sq in
$= 12\,500 - [(500 \times 9.2)/1.34] = 9.070$ lb per sq in

hat there is ample strength and stiffness and that the area is in-76 sq in. If two 5 by 3½ by 7/16-in angles had been used, the area een increased 0.96 sq in (page 363). The least radius of gyration pression for S_1 assumes that the angles will be separated by ¼-in If thicker gusset-plates are used, the value of r will increase.

tails. The use of UNIFORM SIZES for members in the same straight ical and adds rigidity to the truss. The angles can be furnished of 60 ft and over, thereby reducing the labor of cutting them and number of rivets and the size of the gusset-plates. The portion EG shown by Fig. 7 would be completely riveted up in the shops, hree joints to be riveted at the building. In general, any truss outside dimension not exceeding 10 ft, can be shipped by rail. he location of the splices.

3. Joints of Wooden Trusses

of any truss should be proportioned with as much care as is used the sizes of the members, so that the truss will be equally strong s. The general principles and methods for designing joints are hapter XII and illustrated by examples. To further explain the ethods of design of some of the joints for the trusses shown in are added in this chapter.

1. This is the most important joint in the truss. There are this joint, but only a few of them are illustrated. Fig. 8 shows a JOINT. The rafter rests in a notch in the bottom chord and is y one or more rolled-steel bolts. These bolts are perpendicular he rafter, and the stresses in them are found graphically by the ig. 8) in which ac is perpendicular to the SCARF-CUT or SEAT of e tension in the bolts is found to be 31 550 lb, and with a permis-16 000 lb per sq in, the net section-area required is 1.97 sq in, nds to one 1⅞-in bolt (Table II, page 388). The WASHER, bear-grain of the rafter, will have an area of 31 550/200 = 158 sq in ince the top-chord is actually but 5½ in wide, the length of the 8 in. Such a plate would look out of proportion with one bolt, ts are substituted, having a net section-area of 2.10 sq in (Table Two bolts are placed near each end of the plate and one bolt middle. The bolts are spaced about 9½ in apart. The thick-e may be taken as one-fifth the distance from the end of the s of the first pair of bolts. This distance is about 3.4 in; hence 0.67 in. A ¾-in plate is used. The lower end of each pair of l with a PLATE-WASHER bearing upon the inclined surface of the ER as shown. The ANGLE OF INCLINATION approximates 45°

and hence the allowable pressure on the wood is 500 + (1 400 − 500) ¼ = 72 per sq in. (See Table VI, page 454, Table XVI, page 647, and the equatio page 1138.) The pair of bolts carry a tension of 31 550 × ¾ = 12 620 lb, this stress requires a plate having an area of 12 620/725 = 17.4 sq in, w will be provided by a plate 5¼ by 4 by ¾ in. For the single bolt, a 4 by CAST-IRON BEVELED WASHER is used, having a ¾ in lug let into the bol to take the horizontal component of the pull in the bolt. To prevent the bol slipping on the bottom chord, two OAK KEYS are employed. (See Table page 454, and Table I, page 1138, for permissible unit stresses.) The horizo component of the pull in the bolts is about 22 300 lb, and for one key, 11

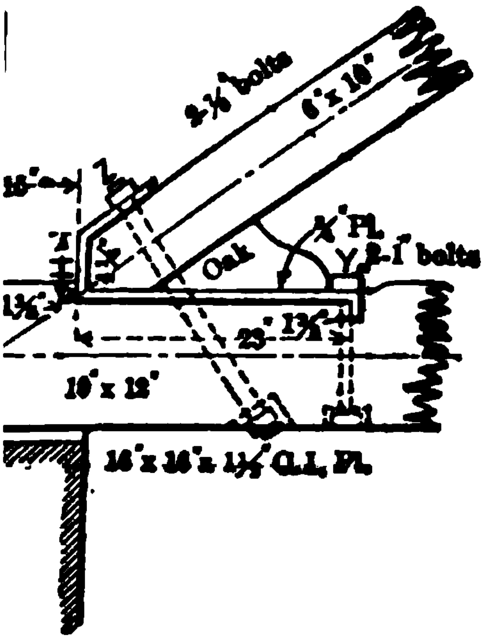
Fig. 8. Detail of Joint 1, Fig. 1

lb, and taking the actual thickness of 6 in to be 5½ in, each inch in lengt the key will safely carry 5½ × 200 = 1 100 lb in longitudinal shear (Tab page 412). The keys will, therefore, be 10 in long. The ends of the keys against the notch in the white-pine chord, and for end-bearing each in depth of the notch carries 5½ × 1 100 = 6 050 lb. The depth of the n therefore, is 1.8 in in the chord. In the bolster each inch in depth of n carries 5½ × 1 400 = 7 700 lb (Table XVI, page 647), and the depth of n is 1.43 in. This makes the total thickness of the keys 1.8 + 1.43 = 3.23 in, say 3½ in. The size of the keys is 3½ by 5½ by 10 in. The SPACING OF KEYS is governed by the longitudinal shear of the white-pine chord. E inch in length carries 5½ × 100 = 550 lb (Table I, page 1138), and the distance between keys is 11 150/550 = 20 in. The various dimensions above will probaby appear large to many. The large dimensions are du the timber used. If long-leaf yellow pine had been employed, many of dimensions would have been materially smaller. The ANGLE-BLOCK d shown in Fig. 9a, makes a much better connection in this case. 1½ becomes 1¼ in and 15 in becomes 13 in. The net area of the bottom c should now be determined to see if it is sufficient to take the tension.

Wall-Plate. As a rule it is a good idea to place the WALL-PLATE, w receives the common rafters, just above the bottom chord as shown. affords an opportunity to get at the nuts on the bolts to tighten them a wood shrinks. The BEARING OF THE TRUSS on the brickwork should be

ıd a STONE OR METAL PLATE provided to distribute the pressure. (See XIII.) In this case a 16 by 14 by 1¼-in CAST-IRON PLATE is used, uces the pressure on the brickwork to 82½ lb per sq in.

Fig. 8. This joint might be made in the manner described above, ype shown in Fig. 9 is used. The thickness of the plate is usually by the thickness required at *Y* to give the HOOK the proper strength.



Detail of Joint 1, Fig. 3

ers because the materials are readily obtained, yet for important structures t writer believes it is worth while to use a little more effort and pay a little m to get SOLID STICKS for truss-members.

Wall-Joint of Scissors Trusses. In SCISSORS TRUSSES the joint over t wall formed by the rafter and tie-beam should always be carefully proportion

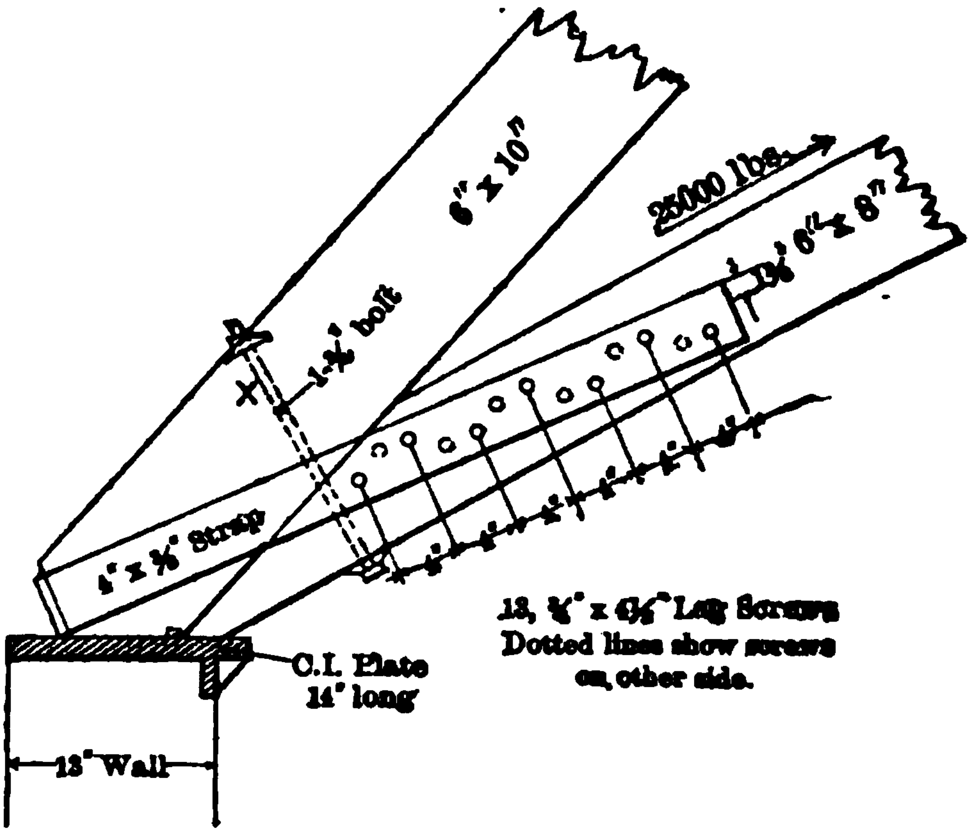

Fig. 18. Wall-joints for Scissors Trusses, Figs. 24 to 27, Chapter XXVI

to the stresses; otherwise the joint is liable to open and the wall to be push out. Much greater strength is required in this joint than in the wall-joint o KING-ROD TRUSS of the same span, because the stresses in a SCISSORS TRUSS usually at least twice and sometimes three or four times as great as in a tru with a horizontal tie-beam. For a SCISSORS TRUSS built of planks, as in Fig.

t through the center of each joint, with as many spikes as can be l ordinarily give sufficient strength. For trusses like those shown in 27 of Chapter XXVI, one of the best methods of making the wall-s the roof is quite flat, is that shown in Fig. 18, which is the detail l joint where the stress in the tie-beam was 25 000 lb. It should be t the WROUGHT-IRON STRAP is secured to the tie by LAG-SCREWS in-OLTS. It is practically impossible to bolt a strap to each side of a to get a good bearing for all of the bolts, owing to the difficulty in holes straight; and if the holes are bored a little large, some bolts on the wood and some may not. With LAG-SCREWS each screw is et a good bearing in the wood. The holes in the two sides of the , of course, be staggered, so that they will not come opposite each e net sectional area of the strap should at least be equal to the stress eam divided by 2 × 12 000 (Table I, page 1138). The number of , for both sides, is found by dividing the stress in the tie-beam by ce of one screw. For the safe resistance of LAG-SCREWS used in this lues given in Table V are recommended. In the joint shown in Fig. ss in the tie-beam is 25 000 lb, and the wood is Douglas fir. The therefore, require a sectional area in the strap of ½ (25 000)/12 000 = d twenty-three ¾-in lag-screws. Only thirteen are shown in Fig. 18.

Safe Resistance of Mild-Steel Lag-Screws When Used as in Fig. 18

ickness of ⅜ in, the width of the strap necessary to give a sectional q in is 1.05/.375, or about 3 in. To this should be added the diam-ag-screw to obtain the working width. Thus 3 + ¾ = 3¾ in. The 4 by ⅜ in in cross-section, as some additional strength is obtained by , which it is necessary to insert to hold the timbers together while eing raised into position, and also to bring them tightly together the strap. Fig. 19 shows another method of making this joint e used with advantage when the inclination of the rafter is less ne advantage in using this truss is that if it is erected ONE PIECE e tie-beams may be put up first, thus providing a SEAT to receive The strap prevents the end of the rafter from springing up. The he bolt should be proportioned to the horizontal component of the rafter. Fig. 20 shows a good form of joint to use at joint 5 of Fig. XXVI, when it is desired to substitute a wooden tie for the rods 27. The sectional area of the strap and the number of lag-screws portioned by the rules given for Fig. 18.

Where iron or steel rods are used in wooden trusses, washers are der the heads and nuts to properly distribute the loads on the dimensions of the washers are determined by the allowable bear-

ing pressure on the wood and the magnitudes of the loads. Table VI gives th allowable loads which can be transmitted by standard round cast washers an rectangular washers bearing across the wood fibers. Table VII gives the di mension of standard round cast washers. The bearing areas of these washe

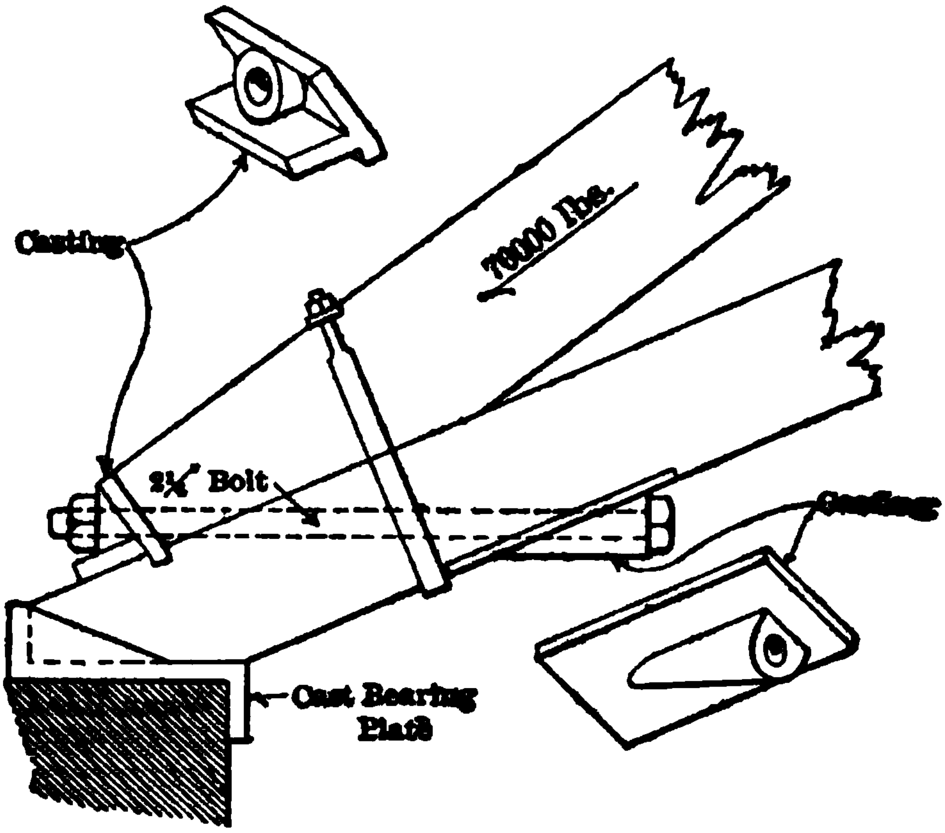

Fig. 19. Alternate Detail for Fig. 18

are too small for use on the softer woods and, therefore, except when the rod are small, it is better to use rectangular washers of iron or steel plate. Very large washers should be cast, and should have the form shown in Fig. 20A. The use of the ribs gives the required strength and saves considerable material

4. Joints of Steel Trusses

Trusses with Riveted Joints are usually made with ANGLES for the we members and generally for the chords, although the latter are sometimes ma of a pair of CHANNELS or of two ANGLES and a WEB-PLATE. The members a connected at the joints by means of GUSSET-PLATES, to which all of the membe are RIVETED. Typical examples of riveted joints in roof-trusses are shown Figs. 22 to 24E. When the rafter or chord has a WEB-PLATE, as in Fig. 23 the web-members are riveted to this plate and a GUSSET-PLATE is not requir except at the end-joint and apex, as shown in Figs. 23A and 23E. In order th there shall be no twisting, it is necessary to make the principal members of t truss DOUBLE, so that the gusset-plates can be riveted between them. Whe single angles are used for web-members and two such members come at a joint they should be riveted to opposite sides of the gusset-plates. For equ strength the thickness of the gusset-plate should be such that the BEARING the rivets equals the strength of the rivets in DOUBLE SHEAR, the thickness, ho ever, not exceeding the combined thickness of the two angles. Practical co siderations seldom make the gusset over ⅜ in thick for ordinary constructi

joints, which should be done to a scale of not less than 1 in
mbers should be arranged, when practicable, so that the lines
eir centers of gravity will coincide with the lines of the truss-
meet at a single point, as in Fig. 21. This is not always prac-
prin-
owed
sible.

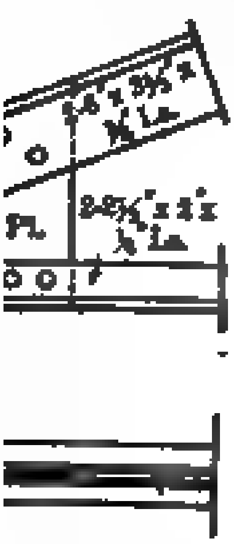
siderations, Truss of Fig. 7. It is assumed that the truss
three parts, making all the joints SHOP-RIVETED except those
ices at each end of the piece *EH*. All gusset-plates are to be
ll rivets ¾-in, except in the 2-in legs of angles, where ⅝-in
used. Since the bearing of a ⅝-in plate on a ¾-in rivet at
in (Table I, page 1138) is 5 630 lb, or at 18 000 lb per sq in
419) is 5 060 lb, and the resistance of the rivet in double shear,
lb (Table III, page 419), the number of rivets in all the joints
he bearing value. Only one leg of the angles will be connected



tail of Joint *A*,
ss, Fig. 7

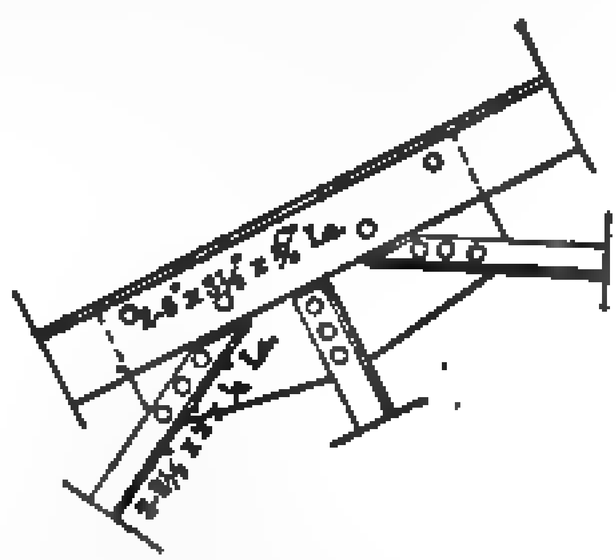


Fig. 22A. Detail of Joint *D*, Fink Truss, Fig. 7

ate as about 80% of the full strength of the angle is thereby
t less than three rivets are used. The use of HITCH-ANGLES
ing leg has but little influence in increasing the efficiency of the
o rivets may be considered the minimum number in any con-
ss of the unimportance of the member.

1. The top-chord stress is 23 500 lb, and if one rivet carries
e gusset-plate, five rivets will be required to carry this total

stress. In like manner four rivets are required for the bottom chord. T supporting force or the reaction is transferred to the gusset through the bott chord prolonged. In this case the reaction is about 8 800 lb which requires t rivets. Fig. 22 shows the arrangement of this joint at the expansion-end.

Joint D, Fig. 7. The web-members each require less than one rivet, but t or three should be used. Since the top-chord angle is continuous, the numbe rivets in it is determined by the difference between the two adjacent stres and the load of the purlin if it rests on the chord. Here again the number rivets required falls below the minimum number. Fig. 22A shows this joint.

Joint E, Fig. 7. The piece *CE* requires four rivets and the web-members t minimum number permissible. The piece *EH* requires, at 20 000 lb per sq

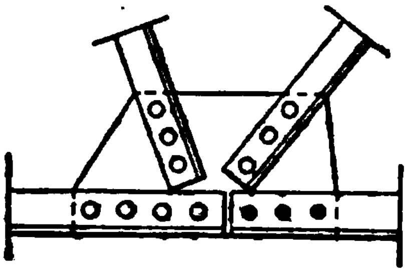

Fig. 22B. Detail of Joint *E*, Fink Truss, Fig. 7

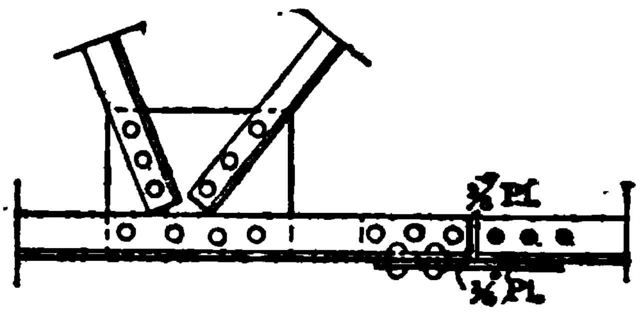

Fig. 22C. Detail of Joint *E* and Splice in *EH*, Fink Truss, Fig. 7

bearing value, 12 500/5 630 = 2.22 rivets; but as this connection is one to made IN THE FIELD, it is customary to increase the number 25%. This mak the required number three. Sometimes the outstanding legs are spliced to t member *CE* by a plate. Without doubt this increases the strength of the joi but it is doubtful if the increase in strength is enough to offset the extra co Fowler's specifications do not permit the piece *EH* to be connected to t gusset-plate. They specify that the connection shall be made upon the right *E*. This arrangement allows the use of a smaller gusset-plate at *E* which m be counterbalanced by the a ditional metal required for t splice beyond *E*. (Figs. 2 and 22C.)

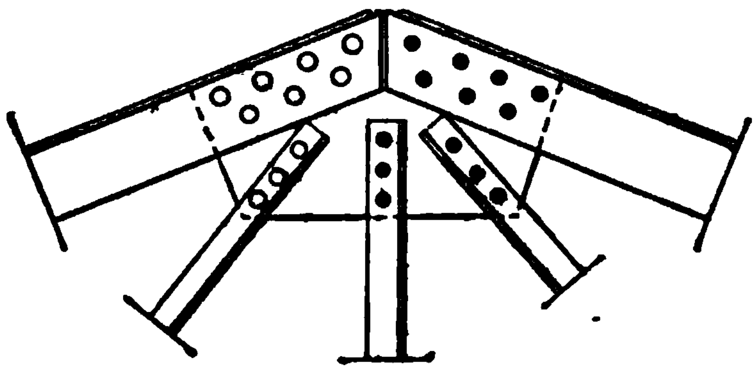

Fig. 22D. Detail of Joint *G*, Fink Truss, Fig. 7

Joint G, Fig. 7. The piec *BG* and *FG* are SHOP-RIVET to the gusset on one side a FIELD-RIVETED on the other. I order to make the joint sym metrical, the number of SHO RIVETS is made the same required for the FIELD-CONNECTION. In this case the top chord requires f rivets and the web-member three. Two rivets may be used in the sag-ti (Fig. 22D.)

Field-Connections. Bolts are often used instead of rivets for making FIEL CONNECTIONS. If the bolts fit the holes snugly, there is no serious objection t their use. In fact a good bolt is better than a poor rivet. For important wor however, bolts should not be used unless turned true to size and driven into tr holes. Open holes or holes for FIELD-RIVETS are indicated by BLACK CIRCLES.

Shop-Drawings. It is not advisable for the architect to make compl drawings for the steelwork. He should make what are usually designated GENERAL DRAWINGS. These are made to scale and give the general dimensi

and sizes of the various members, and show each rivet approximately in its proper position. The manufacturer who fabricates the structure prefers to make his own SHOP-DRAWINGS to conform with his standards and methods.

Examples from Practice. Figs. 23 to 23E show the details of a modern shop-truss. These details were taken from the SHOP-DRAWINGS but with the rivet-spacing omitted. No metal under 5/16 in thickness, or rivets under 3/4 in

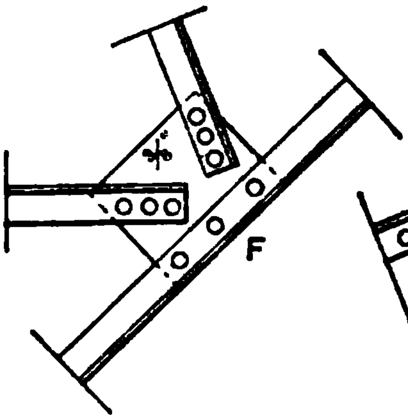

Fig. 23D. Detail of Joint *F*, Fig. 23

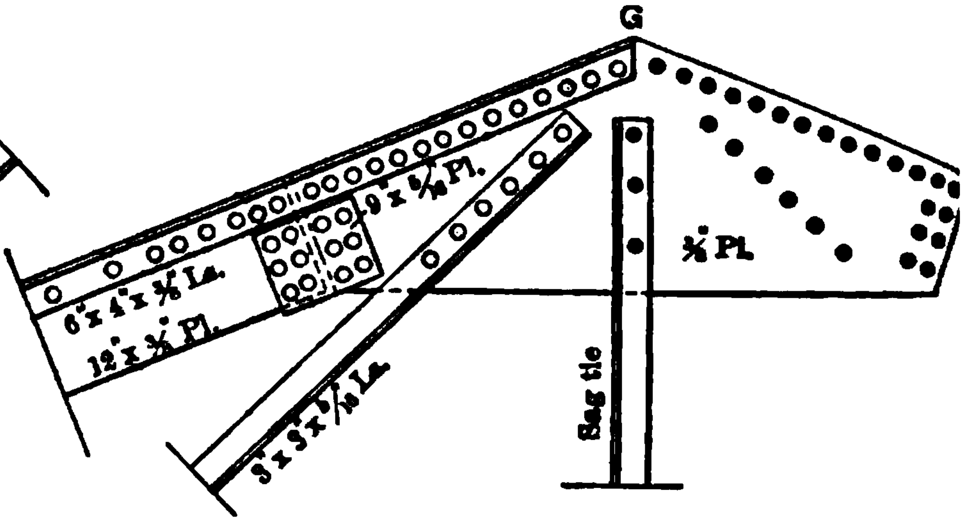

Fig. 23E. Detail of Joint *G*, Fig. 23

in diameter, are used. Another point may be mentioned in connection wit this truss; very few BEVEL-CUTS are made. The contrary appears to be th case for the details of the very light truss shown in Figs. 24 to 24E, in whic BEVEL-CUTS are made on the angles and more cuts than necessary on the gusse plates. These two trusses were designed by manufacturers widely separate

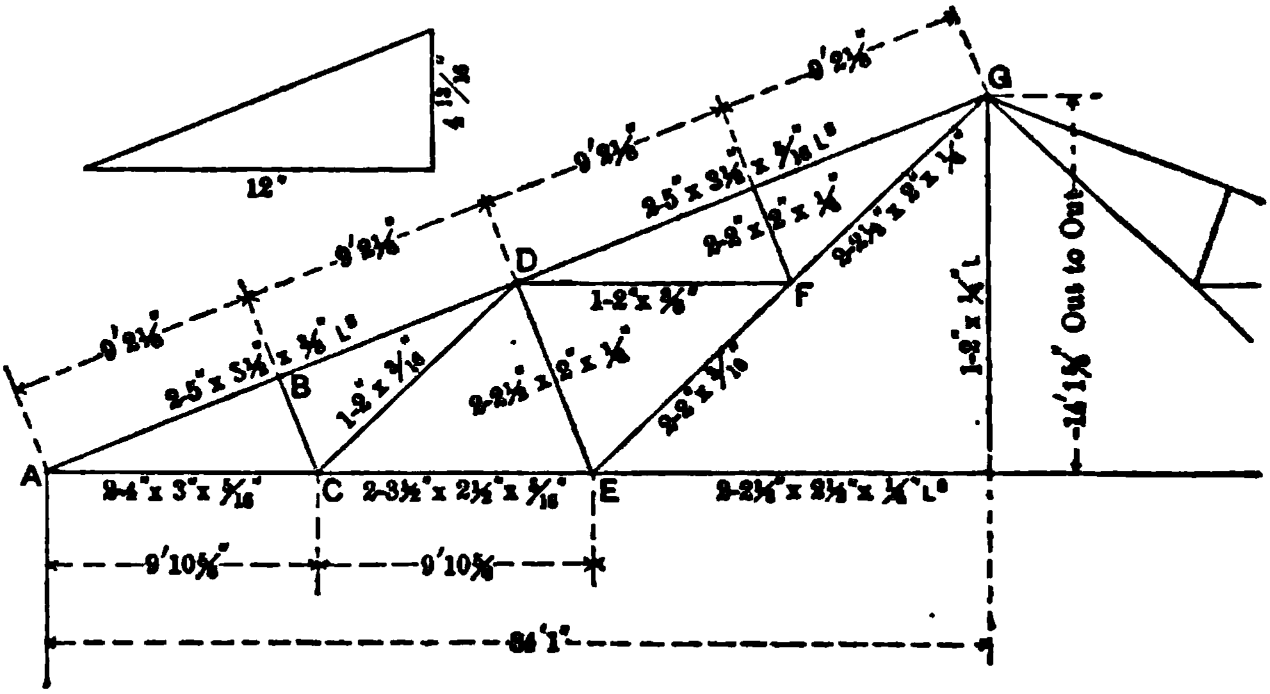

Fig. 24. Fink-truss Diagram. (See, also, Figs. 24A to 24F)

and are quite different in their details; and the variations emphasize the fa that the architect should not attempt to make SHOP-DRAWINGS.

Trusses with Knee-Braces. Fig. 25 represents joint 1 of Fig. 55, Chap XXVI, and was engraved from the WORKING DRAWING made by the New Jer Steel and Iron Company, Trenton, N. J. Another detail of a truss-connecti to a column is shown in Fig. 26. This was used in the template-shop roof-tru Ambridge plant of the American Bridge Company, Ambridge, Pa. Fig.

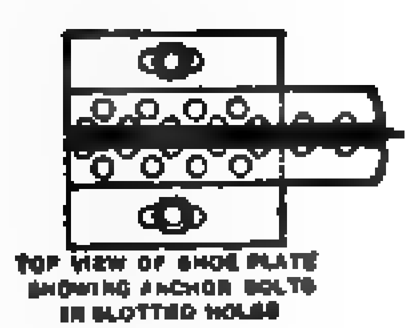

Fig. 27. Wall-end of Steel Truss. Support and Anchoring-details

This condition is seldom considered by architects. Usually it is possible witho any extra expense to satisfy this requirement and thereby to a great extent p vent unknown bending-stresses.

5. Purlins and Purlin-Connections

Where the roofing is supported directly on the PURLINS, as is gen-
ase in light steel roofs, the purlins and trusses are usually spaced so
ıer that SIMPLE ROLLED SHAPES may be used for the purlins. For

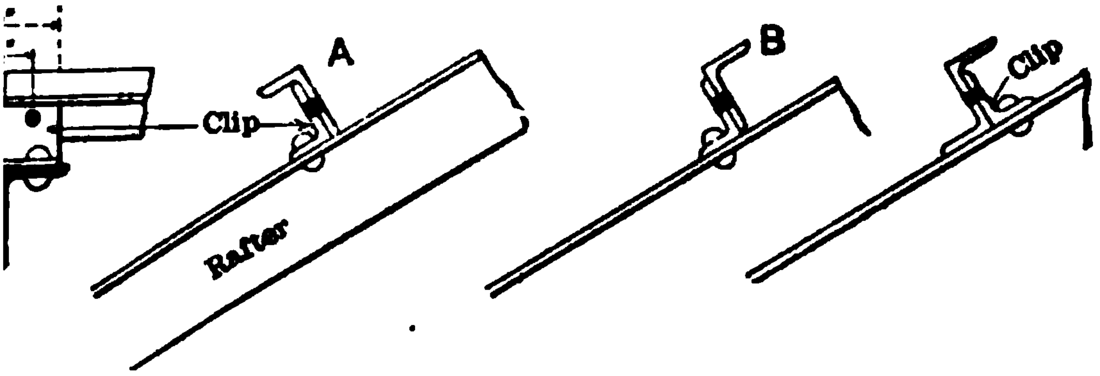

Fig. 28. Purlin-connections. Steel Clips, Angles and Z Bars

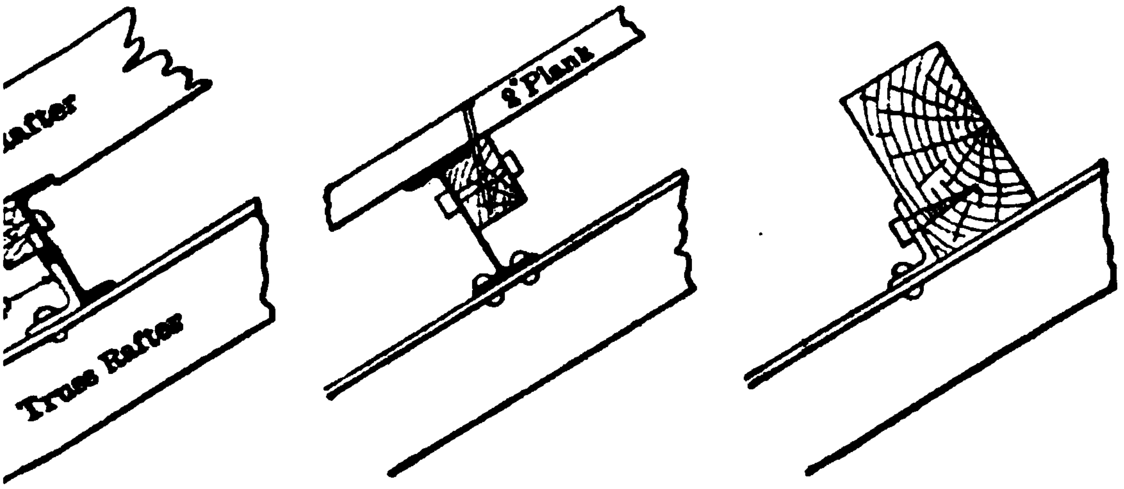

). Purlin-connections. Steel Sections with Wooden Nailing-strips

n trusses of from 8 to 10 ft, ANGLES are commonly used, and for
, Z BARS, CHANNELS and I BEAMS. WOODEN PURLINS are often used
ısses. If STEEL PURLINS support wooden rafters or plank roofing,
RIP of wood is bolted to the purlin, as
29. When the distance between purlins
ıre, a line of ⅝-in rods should run from
ıugh the purlins, to prevent them from
: plane of the roof. The purlin at the
ıe designed to take the vertical com-
stress in these rods.

ır the stress in the outer fiber is true
ɜd with reference to the PRINCIPAL AXES of the section. Then,
ıl axis does not lie in the plane of the loading, the loading must
ıto two components, respectively parallel to the two principal
so, pages 573 and 593.)

Let S' = the fiber-stress with reference to the principal axis, AA, for the re tangle, 1–1 for the I beam and channel, and 4–4 for the angle and Z bar. M' the bending moment of the component of the load which lies in the plane p pendicular to the above axis. I' = the moment of inertia of the section wi

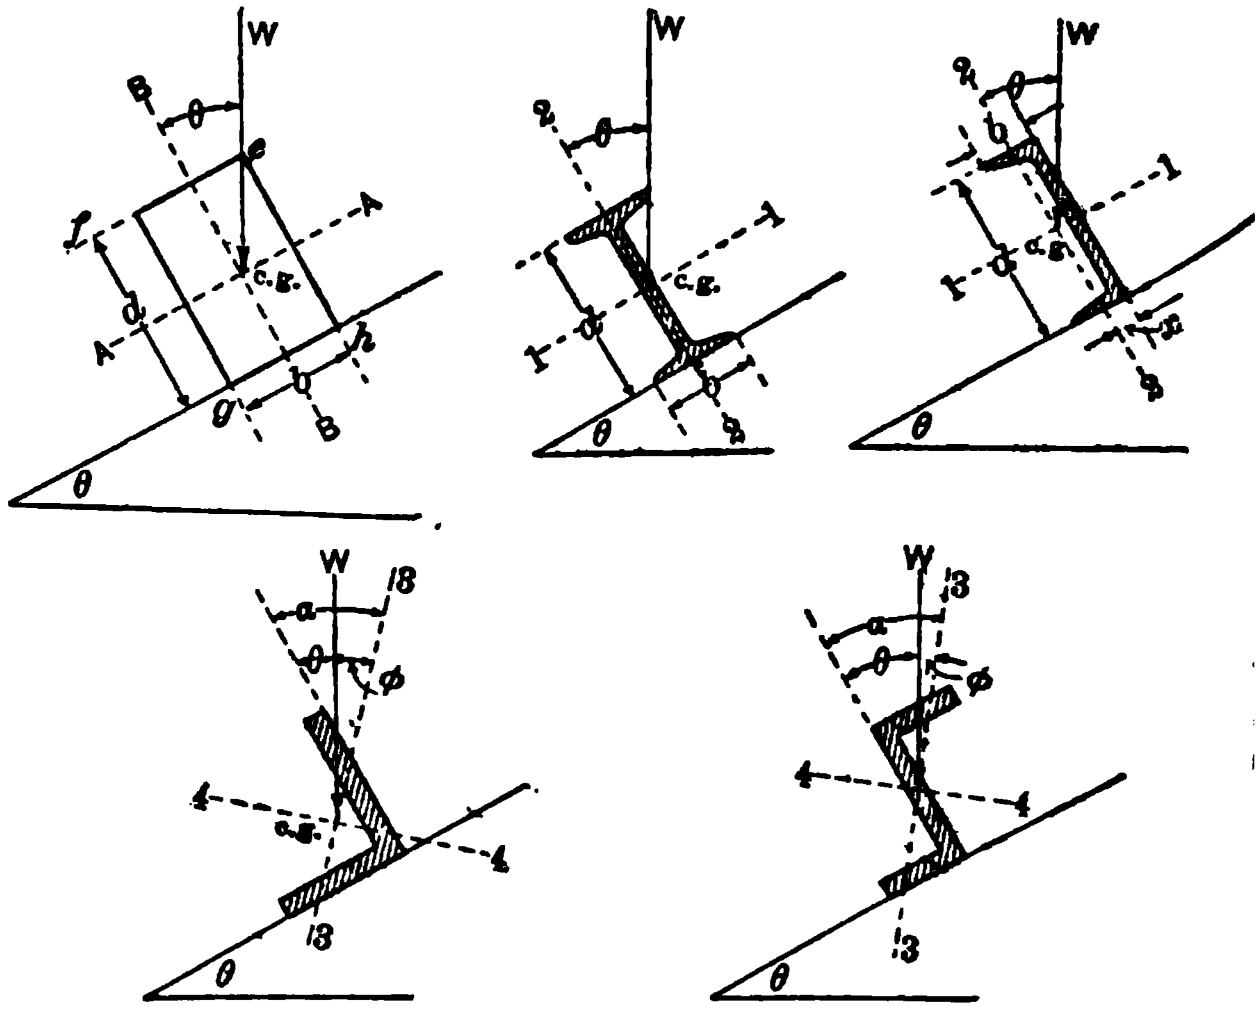

Fig. 31. Sections of Wooden and Steel Purlins

reference to the above axis. c' = the distance of any selected fiber from above axis. For the other principal axis use S'', M'', I'' and C''; then if the resultant fiber-stress,

$$S = S' + S'' = M'c'/I' + M''c''/I''$$

For the rectangle,

$$S = S' + S'' = 6\,M'/bd^2 + 6\,M''/b^2d$$

For the channel and I beam,

$$S = S' + S'' = M'd/2\,I_{1-1} + M''b/2\,I_{2-2}$$

For the angle and Z bar,

$$S = S' + S'' = M'c'/I_{4-4} + M''c''I_{3-3}$$

The application of these formulas offers no difficulties except in the c of ANGLES and Z BARS. For the other forms, the values of I and c are giv the tables of properties of the sections (Chapter X). The locations of the cipal axes for the Z bars and angles are also given in the tables, but the v of c are not given for any of the fibers. The easiest way to get the value in any particular case is to draw the section of the angle or Z bar full size, la the principal axes and then measure the actual distances, c.

CHAPTER XXIX

WIND-BRACING OF TALL BUILDINGS

By

N. A. RICHARDS

OF

PURDY & HENDERSON, INC., CIVIL ENGINEERS

1. Data for Wind-Pressure. Building Laws

ildings of Modern Construction, that is, buildings with skeleton light curtain walls or filler walls, require that resistance to wind-considered with care. The proportions of a building and the arrange-trength of the walls determine to what extent special bracing must l. Building ordinances in the larger cities usually require consider-stated wind-pressure. Where such ordinances do not definitely fix d pressure, a unit force of 30 lb per sq ft of surface is generally proper and adequate. (See, also, page 150.)

Laws. The following are extracts * from the building ordinances of City, Chicago, Philadelphia and Baltimore with reference to wind-

New York (1917)

CONSIDERED. All buildings over 150 ft in height and all buildings buildings in which the height is more than four times the minimum limension, shall be designed to resist a horizontal wind pressure every square foot of exposed surface measured from the ground to e structure, including roof, allowing for wind in any direction.

Y. The overturning moment due to wind pressure shall not exceed of the moment of stability of the structure, unless the structure is hored to the foundation. Anchors shall be of sufficient strength ry the excess overturning moment, without exceeding the working bed.

LE STRESSES. When the stress in any member due to wind does per cent of the stress due to live and dead loads, it may be neg-n such stress exceeds 50 per cent of the stress due to live and dead rking stresses prescribed may be increased by 50 per cent in design-bers to resist the combined stresses."

Chicago (1915)

ngs and structures shall be designed to resist a horizontal wind enty pounds per square foot for every square foot of exposed sur-case shall the overturning moment due to wind pressure exceed er cent of the amount of stability of the structure due to the dead

produced by wind forces combined with those from live and unit stress may be increased fifty per cent over those given above; shall not be less than required if wind forces be neglected."

rally. Form in general not edited or changed. Some paragraph-captions ate editor.

Philadelphia (1915)

WIND PRESSURE. "In all buildings allowances shall be made for wind pr sure, which shall not be figured at less than thirty pounds per square foot elevation where erected in open spaces or upon wharves. In high buildin erected in built-up districts, the wind pressure shall not be figured for less th twenty-five pounds at tenth story, two and one-half pounds less on each succe ing lower story, and two and one-half pounds additional on each succeed upper story, to a maximum of thirty-five pounds at fourteenth story and abo

WIND BRACING. "Wind bracing may be provided by making the connect joint between girders and columns sufficient for the vertical load as well as bending due to side pressure; or brackets may be placed at this joint, prop tioned for the side pressure; or diagonal bracing may be placed between colum proportioned to transfer the shear of the side pressure to the footings.

BASE OF COLUMN MUST BE ANCHORED. Where buildings are narrow tall, so that the overturning due to wind is more than the down pressure of unloaded building, the base of column must be anchored down to a suffici foundation to counteract this upward strain." *

Baltimore (1914)

WIND PRESSURE. "All new buildings exposed to wind shall be made str enough to resist a horizontal wind pressure in any direction of thirty pounds square foot of exposed surface, measuring the entire height of the building.

CALCULATION OF. "The additional loads caused by the wind pressure u beams, girders, walls and columns must be determined by calculation and ad to other loads for such members, as provided for in Section 19 of this Artic

SPECIAL BRACING. "Special bracing shall be employed wherever neces to resist the distorting effect of the wind pressure.

OVERTURNING MOMENT. "In no case shall the overturning moment du the wind pressure exceed fifty per cent of the moment of the stability of structure."

Magnitude of Unit Stresses Used for Wind-Pressure. As the ab extracts indicate, it is generally considered proper to use HIGH UNIT STRES when allowing for wind-pressure. The practice is based on the assumption t the HIGHEST UNIT WIND-PRESSURE will occur very infrequently and that duration usually will be limited to a very few moments. It should be no that the combined stresses due to wind-loads and dead and live loads sho not exceed ordinary stresses by more than 50%. If stresses developed by wind alone do not exceed 50% of those due to dead and live loads, they may neglected.

2. Conditions Determining or Affecting Wind-Bracing

Construction which Resists Wind-Pressure. The dead weight of a bu ing, the exterior walls, the interior partitions and the ordinary connection beams to columns, all aid in resisting wind-pressure, but to a degree whic not determinable in any exact way; and these factors vary greatly, also different buildings. Any allowance for these factors must be largely a quest of pure guesswork, or it may be judgment, based on the resistance which o buildings have offered when no special bracing was provided. It is there best to make special bracing take care of all, or very nearly all, of an ASSU MAXIMUM PRESSURE, when the building under consideration is unusually ligh construction, or when its proportions are such as to make resistance to w pressure a prime consideration.

* Stress is meant.

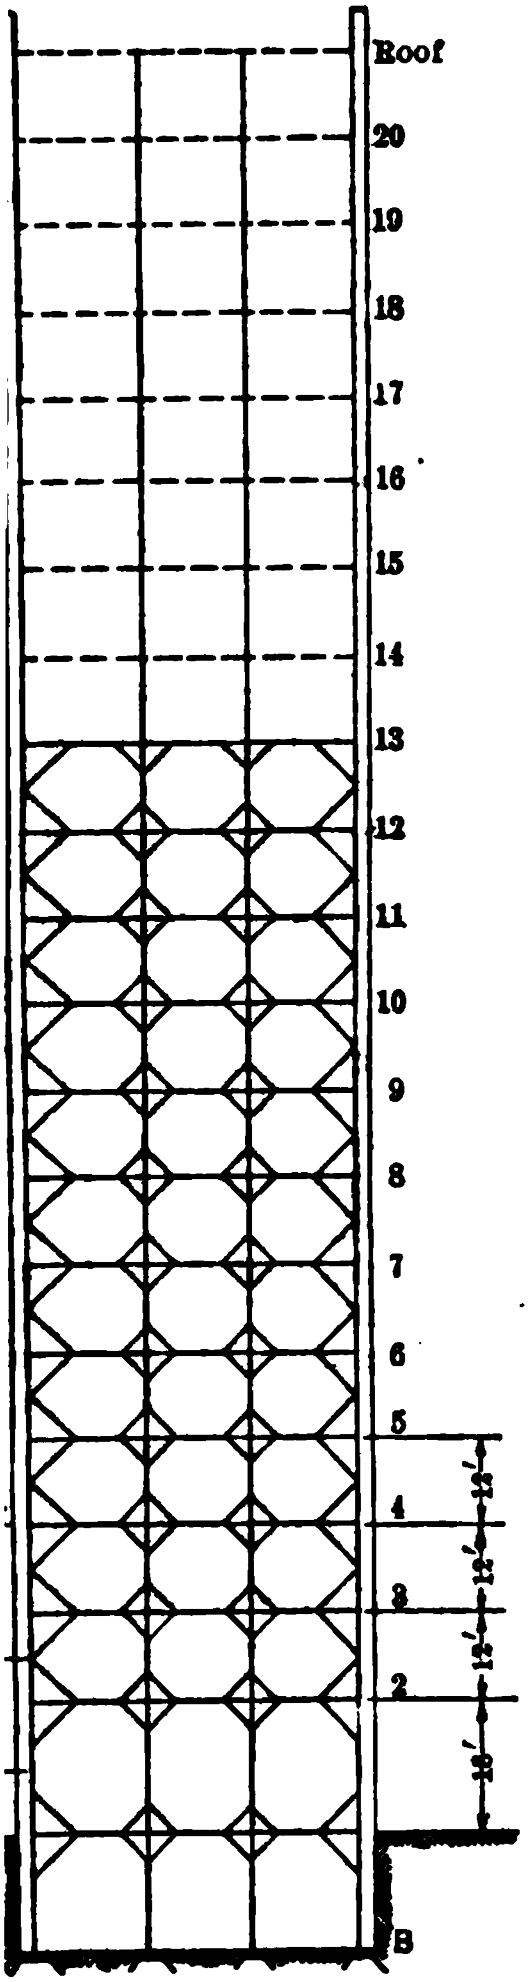
† This refers to a section of the Baltimore building laws.

Width as Affecting Wind-Pressure. It is generally safe to ssure in structural designs for buildings ten stories or less in height, where the average width is not less than one-third the height. It is also usual to omit special provision for wind-bracing in higher buildings where the width is two-thirds the height, or more. The writer believes the above approximations represent conservative practice, so far as general rules are possible.

Dead Load as Affecting Wind-Pressure. A building should not be so proportioned that the OVERTURNING MOMENT of a wind-pressure of 30 lb per sq ft exceeds 75% of the available RESISTING MOMENT of the dead load. If necessary, the columns should be anchored to the foundations.

3. General Theory of Wind-Bracing

Buildings Considered as Cantilevers. Buildings are usually considered to resist wind as



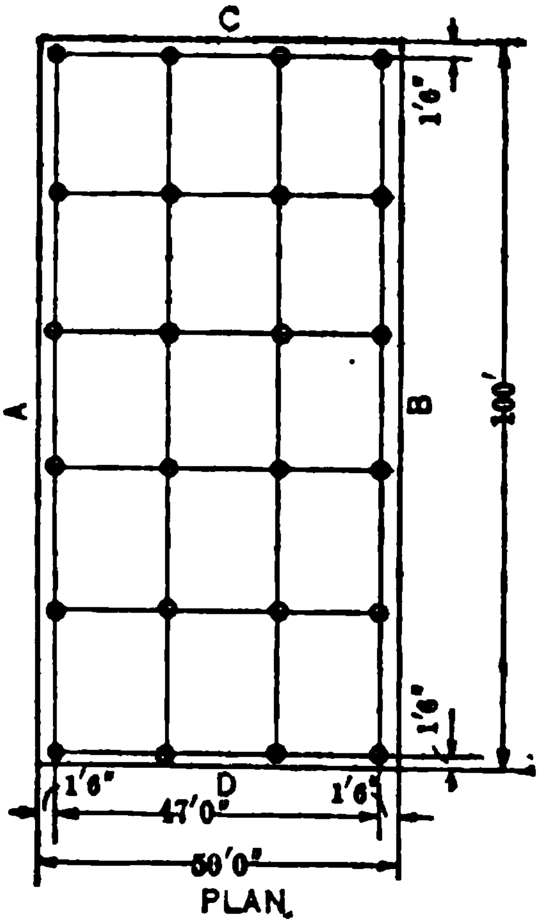


Fig. 1. Section and Plan of Wind-braced Building

RDERS or trusses, planted in the earth. Assuming a building dimensions shown in section and plan in Fig. 1. with a wind-

pressure against side A, the walls A and B, together with the colum beams, etc., in these walls, are the FLANGES of the girders. Walls C and with their framing, together with other intermediate lines of vertical frami form the WEB of the cantilever and transmit the vertical shears. Steel bra ing in horizontal planes is seldom necessary, as ordinary floor-constructio are generally sufficient to transmit wind-loads to the vertical bracing. In so cases, however, it is necessary to add steel bracing in the floors. Such a c is found in the tower of the new Custom-House, in Boston, Mass. The e vators and stairs are next to the west wall throughout the typical stories. Und this arrangement there is no adequate provision in the ordinary floor-constr tion for a wind-pressure on the north or south face to reach the resisting brac in the west face, as the various open wells cut off nearly all direct connecti between the floors and this wall. Flat plates were therefore added on top of t floor-beams at each floor-level, running out from the wall girders behind t wells into the main floor-construction, and attached at each end with conn tions sufficient to transmit the horizontal increment of the wind-pressure each floor to the bracing which resists it.

4. Arrangement of Wind-Bracing

Usual Position of the Bracing. As wind-pressure is assumed to be u formly distributed over the face of a building, it is best to arrange systems bracing, as nearly as may be, symmetrically about the axis of each face. I generally easier to conceal in the exterior walls the required knees, gussets, other braces, and bracing is usually placed there. When the lines of brac have been selected, the areas of wall-surfaces which bring wind-pressure to e are readily determined.

Bracing of Buildings of Irregular Plan. Some buildings are of such sh that it is impossible to provide bracing of equal stiffness in lines symmetri about the center of wind-pressure. This is notably true when the pla TRIANGULAR, as in the so-called Flatiron Building or in the Times Buildi New York City. The result is a tendency in such buildings to TWIST ABOU VERTICAL AXIS. The analysis of the resistance offered by a building to a t of this sort is unsatisfactory and complicated. The stresses produced in usual case, however, are small, if not negligible. In the examples mentio above, provision against twist is made by the use of deep spandrel girders around the building at each floor-level.

5. Types of Wind-Bracing

Ordinary Beam and Girder Column-Connections. Wind-bracing sh be so proportioned that the joints between horizontal and vertical members sufficient to prevent the distortion of the frame, and the main horizontal vertical members sufficient to resist any bending moments produced throug the joints, as well as any direct loads coming on them. The ORDINARY CON TIONS of steel beams to steel columns (Fig. 2) provide considerable resistan a distortion from side thrust. This is also true, of course, of connections bet beams and columns made of cast iron or concrete; but as these types are not adapted to construction where wind-bracing is required, they will not be sidered. A usual connection for beams or girders to columns consists of c ANGLES above and below the beam, and perhaps a STIFFENER below, if the is large. Usually, in high buildings, four rivets are used to connect either to the clip-angles above and below, and four to connect each clip to the col The value of four rivets, in single shear, multiplied by the depth of the b

TING VALUE of such a connection against a moment due to side
er buildings it is usual to specify two rivets instead of four in

as the wind) to columns act at their full value to resist the wind-
otedly wrong, because the many connections could probably not
rk at the same time, and also because building-frames are seldom
at such a result could be possible, under any rational assumption,
he distribution of the vertical shears. SIDE CLIPS are sometimes
olumn-connections to furnish additional stiffness. They are not
, however, as on most beams they are not deep enough to help

umn-Connections in Wind-Resistance. Column-connections
made very heavy, as shown in Fig. 3. A connection of this kind
ed to resist a large TWIST. The RESISTING VALUE is, of course,
he resisting moment of the rivets connecting the beam to the clip
e connection of the angles to the column. This type is used where
to wind is provided for in a very large number of connections,
the column-connections, throughout the building. Such an

arrangement was used in the Hudson Terminal Buildings, New York City There are several objections to this type of connection. Double beams o girders are required, and the resulting finish is awkward in appearance; th cost, also, of double, compared with single, beams and girders, is high. Th additional fireproofing, also, increases the expense, and on the whole, it does no generally prove a satisfactory method of stiffening a building.

The Gusset-Plate Type of Wind-Bracing. In addition to ordinary bea and girder-connections, as described in the preceding paragraphs, there a several distinct types of special wind-bracing commonly employed. Perhap the most common form is the GUSSET-PLATE, shown in Fig. 4. This is no usually an economical type, as it requires much field-riveting and results i large bending moments in the columns and girders. It accommodates itse well, however, to walls in which there are openings, and is generally easily con cealed by architectural treatments.

The Knee-Brace Type of Wind-Bracing shown in Fig. 5 is also com monly used where wind-bracing is placed in exterior walls.

The Sway-Rod Type of Wind-Bracing shown in Fig. 6 is theoreticall the most economical type of wind-bracing, but is now little used. It is difficu to arrange openings in walls or partitions in which the sway-rods are place and they cut up the masonry considerably.

The Latticed-Girder Type of Wind-Bracing shown in Fig. 7 is sometim used where deep bracing is desirable for stiffness, and where the stresses a light.

The Portal Type of Wind-Bracing shown in Fig. 8 is cumbersome a expensive, but is sometimes necessary where large openings are required betwe columns.

6. Computation of Wind-Stresses

The Shears to be Transmitted by Wind-Bracing of any Type are t same in any given case, but the bracing of each type transmits these shears in different manner, and thus each must be considered separately. It is as thoug a PLATE GIRDER with SOLID WEB were set on end in the ground, a side thrust e erted, and the WEB THEN CUT AWAY at successive levels corresponding to t stories in a building. The amount of the shears to be transmitted between t flanges would not vary as holes in the web were made, but the road by which t shears traveled would need to be determined by the character of the resulti construction after the holes were cut; and the exact character of the seconda stresses, also, set up in the remaining portions of the web, would depend e tirely upon the number and size of holes and their position in the web. T investigation of the shears and moments taken care of by the individual membe of a bracing-system may be likened to a study of the secondary stresses in t mutilated web in the imaginary plate girder described above. For a buildi it is generally convenient to determine the VERTICAL-SHEAR INCREMENTS at ea level of bracing, and use these increments in the further analysis of the bendi moments and shears in the individual members of the system.

7. Illustration of Method of Computing Wind-Stresses

Thrusts, Vertical Shears and Moment-Increments. If bracing is plac in the walls *C* and *D*, Fig. 1, it is assumed that one-half the length of the build contributes pressure to each line. Let it be further assumed, for the prese that these lines of bracing are the only features of the construction offerin resistance to wind-bracing against side *A*. Then, assuming the wind to bl

:e per sq ft, perpendicular to side A, there are HORIZONTAL THRUSTS on each line of bracing, of 50 by 12 by 30 lb, or 18 000 lb. Re- e I, page 1178, there are found listed in the second column of the izontal thrusts at each floor. It is assumed that no additional reached the building below the fourth floor. In the third column se horizontal thrusts, ΣH, are summarized from the top down to giving the TOTAL HORIZONTAL THRUSTS. For example, 202 500 lb izontal thrust down to and including the tenth floor. Each tier t transmit a VERTICAL SHEAR equal to the difference in flange- a point midway in the story above the tier in question, and a 1 the story below. This difference of flange-stress can, of course, :ertaining the difference in bending moments between the two ding by the effective depth of the system, as in a plate girder or ow appear that the differences in moments applying to each tier ound and tabulated. These will be called the MOMENT-INCRE- ave been tabulated for the assumed case in the fifth column of ourse, the sum of all the moment-increments must equal the ING MOMENT of the wind. The simplest way to obtain the it for any tier is to multiply the total horizontal thrust, ΣH, el in question by the distance between points midway in the below the tier. Thus, for the tenth floor, 202 500 by 12 equals

nts of Vertical Shear are found by dividing the moment- e effective depth of the cantilever, in this case, 47 ft. The ENTS are listed in the sixth column of the table. It is full depth between outside columns as the effective depth of his is not strictly correct where there are four or more columns bracing, but the assumption is made on the ground that the nish flanges which are so many times more effective than the ins that the latter may be neglected. If there are a number lane of the bracing, say six or seven, this assumption becomes te, and the effective depth should be reduced. The function eretofore stated, is to carry between the flanges at each floor s of vertical shears thus found. The summation of all the from the top down gives the TOTAL VERTICAL LOAD and UP- on the corner-columns, or more correctly, on the outside r.

Shear. In this assumed case, the total uplift exceeds the live loads on the corner-columns. This, however, is not re are sufficient means furnished for transferring any excess the walls A and B, which act as flanges to the wind-resisting rule, the side walls of a city building are not much reduced higher buildings there are usually spandrel beams in the With such an arrangement a considerable amount of EXCESS are of. In some cases special bracing may be necessary, at s of walls A and B.

al or Flange-Stress. When considering any question AL LOAD OR UPLIFT, such as the one described in the pre- should be kept in mind that totals should be used without . Vertical forces forming couples to resist the wind must hey are transmitted through the masonry walls or through Referring again to the illustration of the plate girder set ertical shears are dependent only on the force of the wind

and the effective depth of the girder. The exact WEB-STRESS will vary with th form and arrangement of the web, but the TOTAL VERTICAL OF FLANGE-STRES must remain the same in any case.

Indeterminate Resistance-Factors. An analysis which makes no allowanc for the resistance of walls, ordinary connections, etc., to wind is fairly direc and simple, and the bracing can be proportioned with as much precision as an structural feature. When the wind-resistance of a building is a primary co sideration, as in a tower, the analysis should be made thus, for only in this wa can a result be obtained, where it is not required to rely on almost unsupporte judgment for the value of INDETERMINATE FACTORS OF RESISTANCE. Whe however, ordinary buildings of usual proportions are under consideration, it customary and well to make allowance for the INTEDERMINATE FACTORS, to th best of one's judgment. This is necessary for economy, and is perfectly prop so long as usual cases are to be dealt with.

Scheme for Developing Special Bracing. The writer offers the follo as a reasonable and consistent scheme for DEVELOPING SPECIAL BRACING w such allowances are considered. Unfortunately, it does not seem possibl recommend any method of determining the correct allowances, except such g eral guides as are mentioned in Subdivision 2, page 1172. In each inst some one familiar with construction and usual practice should decide how

a the top it will be safe to assume the building rigid and secure against
iout special bracing. In this case, let it be assumed that the building
of safely resisting the wind, without the aid of special bracing, as far
ie thirteenth floor. Then, assuming that the walls, beam-connections,
in reasonably the same in the floors below, it is fair to say that the
f the increment at the fourteenth floor can be deducted from the
crement at each floor below.

ed Vertical Increments. The CORRECTED VERTICAL INCREMENTS
is manner should be used only in the proportioning of special bracing.
verturning moment of the wind, and the full vertical shears, should
considering all other effects of the wind and the resistance of the
it. It should also be borne in mind that this method of proportion-
; is, at best, largely dependent upon individual opinion, and in any
se it is far better to err on the safe side, even to the extent of disre-
ogether the uncertain factors of resistance. The CORRECTED VERTICAL
s for the assumed case have been listed in the eighth column of
Since the flanges of the building, acting as an upright cantilever
been assumed concentrated in the outside walls *A* and *B* (Fig. 1), it
t the VERTICAL-SHEAR INCREMENTS will be constant from outside to
racing.

Fig. 5. Knee-brace Type of Wind-bracing

dency to distort the frame, changing the angle between the vertical
members; that is, the columns and girders. For this investigation, a
wel is considered, with gusset-plates at either end, as shown. These
ct to prevent the distortion, and since they both, at either end, re-

sist the same wind-action, the twisting moment in each has the same sign. But they twist in the same direction at opposite ends of the girder, there is somewhe along the girder and between the gussets a POINT OF INFLECTION or a POINT OF N BENDING. The position of this point varies with the relative strength of the tw gussets, but for simplicity it is usually assumed midway between them and th are then proportioned to take care of the resulting moments. Let the point inflection in the example be thus taken. As there is no bending moment at th point, the bending moment at any other point on the girder may be found b multiplying V, the increment of vertical shear for the level in question, by t distance from the point of inflection. So, at the toe of the gusset-plate, t bending moment on the girder equals V multiplied by e, and this is the MAXIM BENDING MOMENT ON THE GIRDER. The flange-stress having been determin from this bending moment, it is possible to fix the number of rivets requir to fasten the flanges to the gusset. The connection of the web to the guss must provide for a shear equal to V. V multiplied by f gives the moment pr duced through the gusset at the face of the column. The rivets connecti the gusset to the column must be sufficient to resist this moment.

Points of Inflection occur in the columns midway between the gussets, ju as in the girders. The bending moment in the column may be obtained appro mately by assuming the moment exerted through the gusset-plates to be appl in the form of a couple acting at points two-thirds of the way out from the cen of the gusset to the tips, as indicated. The MAXIMUM BENDING MOMENT IN EA COLUMN will then be the horizontal force P multiplied by d. P is obtained multiplying V by l and dividing by c, l being the distance from the inflecti point in the girder to the axis of the column, and c being the distance betw the inflection-points in the column above and below the girder.

Gusset-Plates on Both Sides of Column. If there are GUSSET-PLATES TWO SIDES of a column, as is usual on interior columns, the maximum bendi moment in the column will be the sum of the maximum moments due to e gusset. Gusset-plate connections are easily arranged with plate girders or w double channels, or even with I beams.

Stresses in Knee-Braces. Let Fig. 5 represent a typical panel of KN BRACING. As described in the preceding paragraphs on gusset-plates, there m be POINTS OF INFLECTION, and consequently POINTS OF NO BENDING, in the gird and also in the columns. These points are assumed midway between the e of the knee-braces in both the columns and girders. Let V be the verti increment for the level under investigation.

Then $$P = Vl/c$$

and the reaction of the girder at the column,

$$R = Va/b$$

Since V and R act always in the same direction, S must be equal to their s Hence $$S = R + V$$

Maximum bending moment on girder $= Va$

or the equivalent

Maximum bending moment on girder $= Rb$
Maximum bending moment on column $= Pd$
Stress in each knee-brace $= \frac{1}{2} S$ cosecant α.

It is evident that R is the shear anywhere between the intersection-poi the center line of the knee-braces and the columns, and that V is the shear i

tween the braces at either end of the girder. All web-splices, and ›itch of flange-rivets, must be proportioned from these shears.

;ement of Braces for No Bending Moment in Girder or Column. ırent from the above that the nearer a and d approach zero the less the ıoments in the girder and column become. If the intersections of the es of the braces can be arranged so that a and d become zero, there) BENDING MOMENTS in the girders or columns.

3races on One Side, Only, of Girder. It is often necessary to :NEE-BRACES ON ONE SIDE, only, of the girder, either above or below. of this kind the girder itself serves as one arm of the brace, and

$$\text{The stress in the single knee} = S \text{ cosecant } \alpha$$

S are as determined above, but there must also be taken into account ntal stress in the girder, due to its action as one arm of the brace.

$$\text{Horizontal stress in girder} = Vl/(\tfrac{1}{2}c - d)$$

nection between the column and the girder must provide for the com- ›n of R vertical and $Vl/(\frac{1}{2}c - d)$ horizontal.

s in Sway-Rods. For the correct analysis of SWAY-BRACING (Fig. 6), l increments should be found in a manner slightly different from that ın Subdivision 1176–9. The pressures are before, except otal pressures top down to ıclude, in each lditional pres- st areas of one- y below. The ›r each level e the story- w. (See sec- 1 and fourth Table I.) The crements are s for the other pt for these ations; and, e vertical in- ıre constant each story. IN ANY DI- als the verti-

ıt in the story multiplied by the cosecant of the angle α (Fig. 6). l that the diagonals are used for tension only and that, consequently, tem acts at a time. Each horizontal member must take compression vertical increment in the story below, multiplied by the cotangent e joints are arranged so that axial lines of members intersect, there ending either in the columns or the horizontal members.

in Latticed Girders. Let V in Fig. 7 equal the vertical increment ŗ. As in the other types, V is constant between the columns, and any diagonal equals V multiplied by the cosecant of α. As in the

GUSSET-TYPE and KNEE-BRACE TYPE, there is no bending at the middle secti of the girder-length, and consequently no stress in the middle section of t top chord. The maximum bending moment in the girder is at the column-fa and this

$$\text{Maximum bending moment in the girder} = Vf$$

The maximum chord-stress is at this same point, and this

$$\text{Maximum chord-stress} = Vf/h$$

The connections of the chords to the columns must provide against this m imum stress.

$$P = Vl/c$$

and the

$$\text{Maximum bending moment in the column} = Pd$$

Stresses in Portal Bracing. It is not possible to analyze exactly t stresses in PORTAL BRACING (Fig. 8), when it is used in connection with colum of continuous section. The analysis given follows that of C. T. Purdy in "Mod Framed Structures." It is considerably the safe side, and for ordinary cases well be followed. In a large building, wh much bracing of this type might be the exact form of the PORTALS should determined, and greater allowance made the effect of CONTINUOUS COLUMNS.

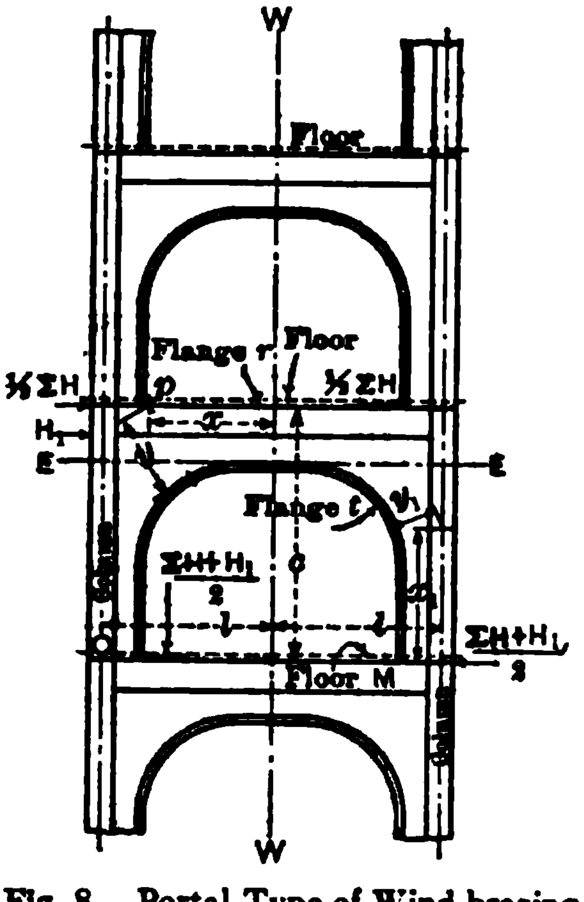

Fig. 8. Portal Type of Wind-bracing

Let ΣH equal the accumulated force horizontal shear from the wind at the fl next above floor M, applied half on side and half on the other. Let H_1 eq the force of the wind or the shear direc tributary to floor M. Then, taking mome about O (Fig. 8)

$$V \times 2l = (\Sigma H + H_1)c$$

or

$$V = (\Sigma H + H_1)c/2l$$

and the

$$\text{Horizontal reaction} = \tfrac{1}{2}(\Sigma H + H_1)$$

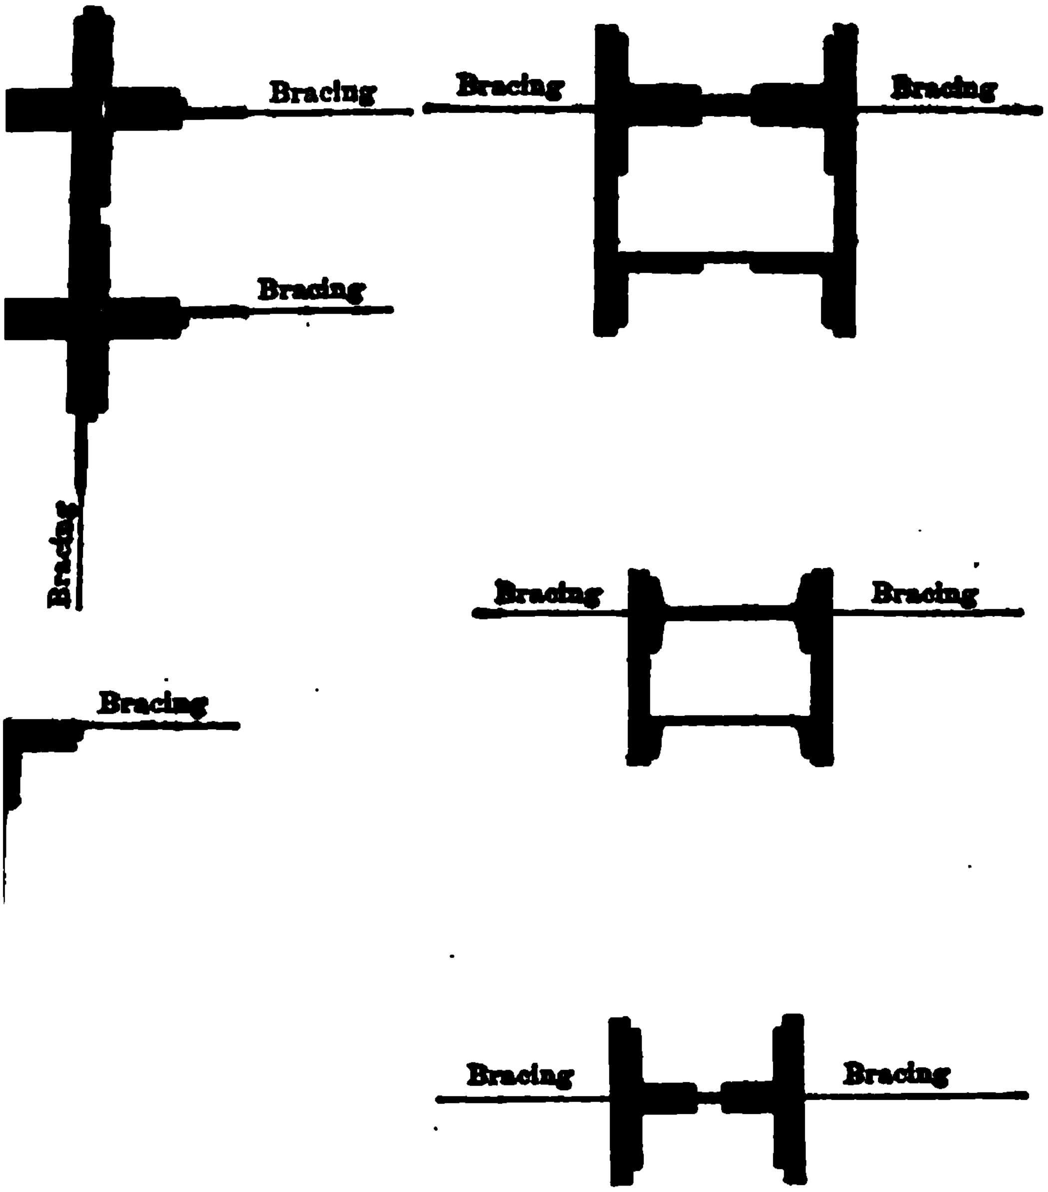
To determine the maximum stress in curved flange t, assume a point p in flange r, horizontally distant x from the line WW, and at the distance y, me ured normal to a tangent to any point in the flange t; then, taking center of moments at the left extremity of the distance x, the stress in flange t multiplied by y, equals V multiplied by x, or Vx/y equals the stres the flange t, at the section taken, and this is a maximum when x/y has its gre est value.

Each leg of the portal, including the column, may be considered as a CAN LEVER with two forces acting on it, the horizontal force $\tfrac{1}{2}(\Sigma H + H_1)$ and vertical force $(\Sigma H + H_1)c/2l$, the flange t (of the right leg for example) be in COMPRESSION and the column itself acting as a TENSION-CHORD. Assumin point on the axial line of the column, distant x_1 from the bottom of the leg at right-angles to, and distant y_1, measured normal to a tangent to any poin the flange t, and taking moments about this assumed point, the stress in flange t multiplied by y_1 equals $\tfrac{1}{2}(\Sigma H + H_1)$ multiplied by x_1, or the stres

uals ½ $(\Sigma H + H_1)$ multiplied by x_1/y_1, and this is a maximum its greatest value. There is approximation in this treatment, e side of safety. If the flange t has a section proportioned to stresses the requirements will be fulfilled. The stress in, and uired for, the flange r can be obtained in a similar manner. The e portal above this flange to the portal and column above must will safely resist the stress ½ ΣH at each leg.

ination of Dead and Live Loads with Wind-Loads

iciples. It usually happens that the same girders that are used serve also to carry floors or walls. The dead and live loads dered with the wind, and the RESULTANT COMBINED STRESSES



9. Types of Columns Arranged for Wind-bracing.

ould be borne in mind that the maximum bending moment l is often at a point on the girder more or less removed from um bending moment for dead and live loads. When RESULT-OMENTS are considered, in which the forces are the wind-load ead loads, it is generally deemed proper to use unit stresses hose of common practice under usual loading. The columns ted for direct live, dead and wind-loads and for the bending RESULTANT STRESS, again, should not exceed 150% of the sed for live and dead loads only. It is often best to design ecial view to proper connections for bracing. This aids in

both design and detail. In Fig. 9 are shown a few TYPICAL ARRANGEMENTS column-material illustrating this point.

10. Wind-Bracing of Water-Towers and Similar Structures

The Principles Involved in Water-Tower Bracing. In the case of TOWER WITHOUT MASONRY WALLS, a problem is presented much simpler th that of a building, as the INDETERMINATE FACTORS OF RESISTANCE are larg eliminated. The bracing sho be designed to resist the wind-pressure. It should borne in mind that in wat towers the condition of MINIM STABILITY obtains when the ta is empty. The most comm form for tower-bracing is SWAY-ROD. The analysis stresses is the same as describ on page 1181. The applicat of the thrust is largely at the where the tank stands, but t does not in any way alter the alysis. The legs of water-tow are frequently SLOPED to giv greater spread at the botto In this case the stresses are m readily determined by GRAP METHODS than by algebr or trigonometrical computati (See Chapter XXVII.)

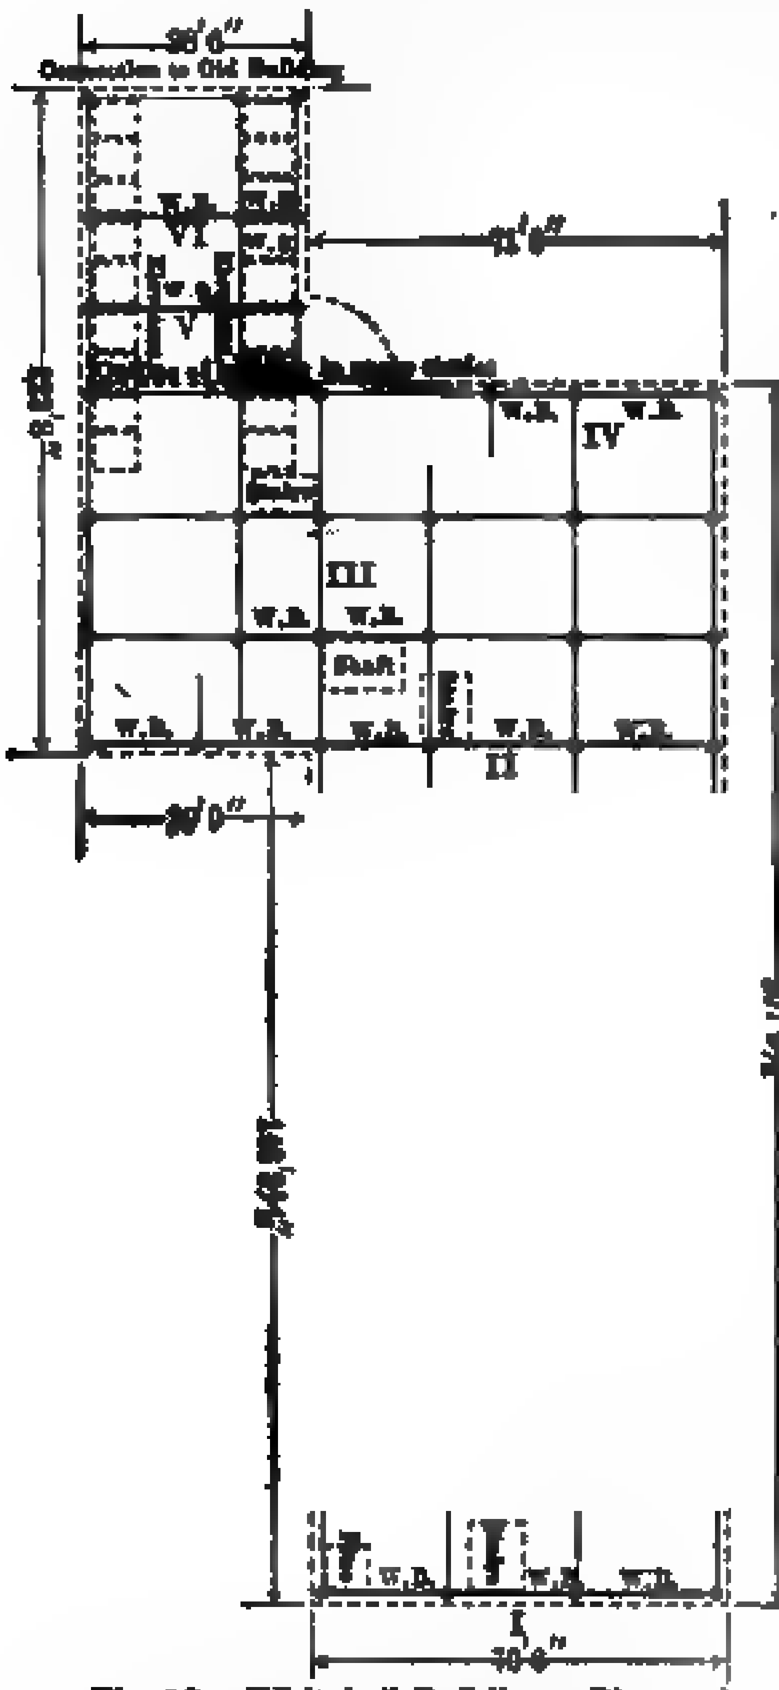


Fig. 10. Whitehall Building. Plan and Lines of Bracing

The Assumed Unit Pr sures should be somewh greater for towers than for bui ings. Towers are small in co parison with buildings, and t probability of the full wind-pr sure being developed over t entire surface is greater. Pr ably 40 lb per sq ft is amp Pressure against a CYLINDRIC BODY, such as a tank, may taken at about two-thirds of t full pressure against the proj tion on the diametrical pla The stresses under this assum pressure should be kept wit usual bounds for ordinary de or live loads. The anchorage each post should exceed, by a safe margin, the full uplift due to the assum pressure. The weight of water in the tank should not be considered as resisti the uplift.

A Good Example of a Steel Water-Tower is described and illustrated the Engineering Record of June 20, 1903, the stress-diagrams and details of co struction being given.

CHAPTER XXX

SPECIFICATIONS * FOR THE STRUCTURAL STEELWO OF BUILDINGS. DATA ON STRUCTURAL STEEL

By

ROBINS FLEMING

OF THE AMERICAN BRIDGE COMPANY, NEW YORK, N. Y.

1. General

(1) **Drawings.** The drawings forming a part of these specifications [give number, maker, title, and date of each drawing].

(2) **Classification.** For the purpose of classification buildings are div into two classes:

I. Mill-Buildings

II. Office-Buildings

Under Class I are included manufacturing plants, machine-shops, po houses, rolling-mills, foundries, forge-shops, pattern and template-shops, t sheds, pier-sheds, car-barns, roundhouses, electric-light stations, armories, buildings of a similar character.

Under Class II are included office-buildings, hotels, apartment-houses, d ings, public buildings (hospitals, libraries, schools, court-houses, jails), plac public assembly (churches, theaters, halls), stores, warehouses, garages, buildings of a similar character.

(3) **Scope of Work.** It is intended that these specifications and dra cover the structural steelwork complete for the building. Cast-iron base included with the structural steel. The steel-erector shall erect in place steel framework on foundations furnished by others. Anchor-bolts, loose li and material not connected with main frame of structure, are to be delivere the site, but put in place by other contractors.

(4) **Materials to be Furnished for Buildings of Class I.** Unless spe otherwise in contract, the materials to be furnished for buildings of Cl include steel trusses, columns, purlins, bracing, floor-framing, crane-girders rails, trolley-beams, lintels, girts, framing around door and window-ope beams supporting tanks, elevator-framing, stair-framing, floor-plates, bu framing and steel lining, stairs and railings unless of an ornamental char cast-iron bases, grillage-beams, and anchor-bolts.

The materials not furnished include ornamental ironwork and steel masons' anchors, carpenters' anchors and irons, elevator sheave-beams, s for trolley-beams, steel stacks, steel tanks, and steel reinforcement for con

(5) **Materials to be Furnished for Buildings of Class II.** Unless spe otherwise in contract, the materials to be furnished for buildings of Cl include steel columns, cast-iron bases, rolled and cast-steel slabs, grillage-be anchor-bolts, floor-framing, roof and ceiling-framing, purlins, cornice-sup supports for tanks, penthouse framing, bracing, and lintels.

The materials not furnished include ornamental ironwork and stee masons' anchors, terra-cotta anchors, carpenters' anchors and irons, stair-

* The various values used in these Specifications agree generally with th throughout the book. Any slight variations in values are due to recognized and al differences in engineering judgment, differences in Building Codes, etc.

raming, elevator sheave-beams, steel stacks, steel tanks, light shapes g metal ceiling-lath, cast-iron sills and similar work, and steel reint for concrete.

VETS AND BOLTS for fastening steel to steel (but not for connecting the other trades) shall be furnished by the steel-contractor. Fitting-up erection are to be furnished by the contractor for erection as a part of nent.

soon as possible a COLUMN-FOOTING PLAN shall be sent to the purowing the location, elevation, and dimensions of all column-bases, with on, elevation, size, and length of all anchor-bolts. The loads coming column-footings from the columns shall also be given.

ine-clearance diagrams showing the CLEARANCES assumed for traveling ll be furnished the purchaser at an early date.

ostitution of Material. If the contractor wishes to substitute OTHER SIZES for those called for on the drawings he may do so, subject to the of the engineer, provided the architectural features are maintained and sections are sufficient to carry the required loads.

ork of Other Trades. HOLES conforming to the usual standards of shall be punched in the steel for attaching the work of other trades, heir location is given while the working drawings are being made.

orking Drawings. WORKING OR SHOP DRAWINGS shall be made by ontractor, and when requested, prints in duplicate sent to the purhis engineer for approval. The engineer's approval of drawings shall eral design, strength and type of details. The engineer shall not be nsible for the fit of work at the site. If, to expedite delivery, or for any on, he waives the approval of drawings, the contractor will not be f responsibility for errors or omissions due to neglect or oversight contractor's) part.

work shall conform to local or state ORDINANCES AND REGULATIONS.

2. Material *

operties and Tests. All parts of the metallic structure shall be of EEL, except column-bases, bearing plates, or minor details, which may IRON OT CAST STEEL.

uctural steel may be made by either the BESSEMER PROCESS or the TH PROCESS; except that rivet-steel, and steel for plates or angles over ickness which are to be punched, shall be made by the open-hearth

ictural steel, if made by the Bessemer process, shall contain not more ,; and if by the open-hearth process, not more than 0.06% of PHOSRivet-steel shall not contain more than 0.06% of PHOSPHORUS nor 0.045% of SULPHUR.

ictural steel shall have an ULTIMATE TENSILE STRENGTH of from 55 000 , and rivet-steel from 46 000 to 56 000 lb per sq in of cross-section. The IELD-POINT as determined by the drop of the beam of the testingall be one half of the ultimate tensile strength.

irements for material are taken, by permission, from the following Standard of the American Society for Testing Materials, Philadelphia, Pa.: Standard for Structural Steel for Buildings (A9-16), Standard Specifications for stings (A48-05), and Standard Specifications for Steel Castings (A27-16).

(17) The MINIMUM PERCENTAGE OF ELONGATION in 8 in shall be 1 400 0 divided by the ultimate tensile strength. For structural steel over ¾ in in thic ness, a deduction of 1 from the above percentage of elongation in 8 in shall made for each increase of ⅛ in in thickness above ¾ in, to a minimum of 18 For structural steel under 5⁄16 in in thickness, a deduction of 2.5 from the abo percentage of elongation shall be made for each decrease of 1⁄16 in in thickne below 5⁄16 in.

(18) TEST-SPECIMENS for plates, shapes, and bars shall bend cold through 18 without cracking on the outside of the bent portion, as follows: For materi ¾ in or under in thickness, flat on itself; for material over ¾ in, to and includi 1¼ in in thickness, around a pin the diameter of which is equal to the thickne of the specimen; and for material over 1¼ in in thickness, around a pin the dia eter of which is equal to twice the thickness of the specimen. The TEST-SPECIM for rivet-steel shall bend cold through 180°, flat on itself, without cracking the outside of the bent portion.

(19) IRON CASTINGS shall be of tough gray iron, true to pattern, free fro cracks, flaws, and excessive shrinkage. The SULPHUR-CONTENTS shall be n over 0.08% for light castings, 0.10% for medium castings, and 0.12% for hea castings.

A TEST-BAR 1¼ in in diameter and 15 in long, placed upon supports 12 in apa and tested under a centrally applied load, shall conform to the following requi ments:

MINIMUM APPLIED LOAD, 2 500 lb for light, 2 900 lb for medium, and 3 300 for heavy castings;

MINIMUM DEFLECTION AT CENTER, 0.10 in.

Light castings shall be able to withstand an ultimate tension of 18 000, medi castings 21 000, and heavy castings 24 000 lb per sq in. Castings having a section less than ½ in thick shall be known as LIGHT CASTINGS. Castings i which no section is less than 2 in thick shall be known as HEAVY CASTIN MEDIUM CASTINGS are those not included in the above classification.

(20) STEEL CASTINGS for ordinary use, not annealed, shall contain not mo than 0.30% of CARBON, nor more than 0.06% of PHOSPHORUS. They shall su stantially conform to the sizes and shapes of the patterns, be made in a wor manlike manner, and be free from injurious defects.

3. Loads

(21) **Roof-Loads.** ROOF-TRUSSES AND COLUMNS shall be designed to car a uniform load per square foot of exposed roof-surface, applied vertically. Th load includes the weight of the structure, the snow, and the wind. For spans u to and including 90 ft, and in climates corresponding to that of New York, t total minimum uniform load in pounds per square foot of roof-surface for differe kinds of covering shall be taken as follows:

	lb p sq
Corrugated metal	[illegible]
Gravel or composition on wood sheathing	[illegible]
Slate on boards	[illegible]
Tile on steel purlins	[illegible]
Gravel or composition on cinder concrete	[illegible]
Gravel or composition on stone concrete	[illegible]
Slate or tile on cinder concrete	[illegible]
Slate or tile on stone concrete	[illegible]
Fire-proof buildings of CLASS II, where slope is less than 2 in per ft	[illegible]

r roof-spans over 90 ft, the above-cited loads shall be increased 1% 2-ft increase of span.

r roofs in climates where snow is excessive, from 5 to 10 lb per sq ft lded, and in climates where there is not liable to be snow, 10 lb per sq ft educted from the foregoing loads.

a ceiling is carried by the roof-framing, the ceiling-load shall be assumed than 10 lb per sq ft.

SHAFTING is carried by the bottom chord, the load at the shaft shall be t not less than 2 000 lb for light shafting, 4 000 lb for ordinary shafting, lb for heavy shafting. Unless the shafting is definitely located these be considered as liable to be concentrated at any point of the bottom

designing PURLINS carrying roof-covering only, the loads in Para-) and (23) may be decreased 5 lb and considered normal to the roof. pitch of the roof is more than from 2½ in to 1 ft, tie-rods shall be used e purlins.

CIAL LOADINGS, such as tanks or elevator-supports above the roof, or trolleys on the bottom chord, shall be taken into consideration.

AT ROOFS used as places of public assembly or for storage-purposes nsidered as floors.

or Loads. Floor loads consist of DEAD LOADS and LIVE LOADS. The s composed of the weight of the floor-construction and of any perma-esting upon it. In designing floor-beams and girders for fire-proof n the dead load shall be assumed at not less than 70 lb per sq ft. of wooden studding or of hollow tile, not more than 4 in thick, may be as part of the live load.

ess governed by a local or state building code, buildings of CLASS I signed for MINIMUM LIVE LOADS, in pounds per square foot of floor-ows:

	lb per sq ft
pattern and template-shops	60
ops, light machinery	120
ops, heavy machinery	150 to 200
	150 to 200
charging-floor	300 to 800
es	200

LDINGS FOR SPECIAL INDUSTRIES shall be designed for the loadings those industries.

vision shall be made for the SUPPORT OF MACHINERY, engines, boilers, other concentrated loads, when carried by the steel construction.

ne-Loads. Loads due to electric TRAVELING CRANES shall be in-, to provide for the effects of impact. For hand-power cranes the be taken at 10%. For two cranes in action on the same girder, no be added, provided the stress obtained is larger than the stress due rane with impact. In addition to the vertical loads the top flanges ers shall be designed to resist a transverse horizontal thrust on each plied at the wheels, of 10% of the lifting capacity of the crane. The ce due to stopping the crane shall be assumed at 20% of each wheel-y be considered as distributing itself along the entire length of the

(34) **Coal-Bunkers.** COAL-BUNKERS shall be assumed to be surcha when it is possible for them to be so loaded. The weight of anthracite c shall be taken at not less than 50 lb per cu ft, and the angle of repose assumed be 30°.

(35) Buildings of CLASS II shall be designed for minimum live loads, in pou per square foot of floor-area as follows:

	lb sq
Dwellings (private residences), first floor	
Dwellings (private residences), upper floors	
Apartment-houses, first floor	
Apartment-houses, upper floors	
Hotels, first floor	
Hotels, upper floors	
Office-buildings, first floor	1
Office-buildings, upper floors	
School-buildings, class-rooms	
School-buildings, assembly-rooms	
Churches and theaters	
Places of public assembly, where floors are used for drilling or dancing	1
Places of public assembly, where floors are not used for drilling or dancing	1
Retail stores, ordinary	1
Warehouses	200 to
Private garages, pleasure vehicles only	
Public garages, pleasure vehicles only	
Garages, motor trucks, from 1 to 3 tons capacity	1
Garages, motor trucks, from 3½ to 5 tons capacity	

(36) CONCENTRATED LOADS shall be taken into consideration. Every st beam in any floor used for business purposes shall be capable of sustaining a l load, concentrated at the middle, of not less than 3 000 lb. Every steel beam the floor of a garage shall be capable of sustaining a concentrated live load 2 000 lb, if a private garage storing pleasure vehicles only; of 3 000 lb, if a pub garage storing pleasure vehicles only; of 8 000 lb, if motor trucks of from 1 to tons capacity are stored; and of 12 000 lb, if motor trucks of from 3½ to 5 to capacity are stored. Structural members carrying elevators and elevat machinery shall be proportioned to carry twice the actual moving dead and l loads.

(37) **Reduction of Live Load.** The full live FLOOR LOAD shall be used in p portioning all parts of buildings designed for warehouses, and such buildings are likely to be loaded on all floors at the same time. In other buildings specified live load may be reduced 10% for girders carrying 200 sq ft or more floor. For COLUMNS the load on the top floor may be assumed at 90% of specified live load; the live load on the floor next below the top floor at 8 and on each succeeding lower floor at correspondingly decreasing percenta provided that on no floor shall less than 50% of the specified live load be u and that for the lower floor the full specified live load shall be used. No red tion shall be made for any ROOF LOAD.

(38) In calculating COLUMN LOADS no reduction of floor-area shall be made stair-wells. Stairways shall be proportioned for not less than 75 lb per sq f horizontal projection.

(39) **Wind-Pressure.** Wind shall be assumed blowing horizontally in a direction. The surface exposed to WIND-PRESSURE shall be measured vertic from the ground to the top of the structure, including the roof.

hen the OVERTURNING MOMENT due to wind-pressure exceeds 75% of
nt of stability the structure shall be securely anchored.

ll steel buildings belonging to CLASS I shall be designed to carry wind-
o the ground by steel framework. For buildings not more than 25 ft
e-line the wind-pressure shall be assumed at not less than 15 lb per sq
corresponding normal pressure on the roof. For buildings more than
eave-line the wind-pressure shall be assumed at not less than 15 lb per
e lower 25 ft and 20 lb per sq ft for the side surface above 25 ft, and
ponding normal pressure on the roof.

e steel framework of fire-proof buildings belonging to CLASS II, in
height is more than twice the minimum horizontal dimension, shall be
o resist a wind-pressure of not less than 20 lb per sq ft on the sides,
rresponding normal pressure on the roof.

e normal pressure, P_n, in pounds per square foot, on a surface inclined θ
the horizontal for a horizontal wind-pressure, P, of 20 lb per sq ft,

ssure other than 20 lb per sq ft these values are to be changed pro-
.

excess of the wind-stresses, determined by the data of this paragraph,
nd-stresses according to Paragraph (21), need be considered. In
this excess, the wind included in the total uniform roof-loads desig-
agraph (21), shall be assumed at 5 lb per sq ft for slopes of 3 in per ft
l 10 lb for slopes more than 3 in per ft.

ULAR STEEL CHIMNEYS and TANKS shall be designed to resist a wind-
ot less than 20 lb per sq ft on the projected area, that is, the diam-
ed by the height.

SIGNS on tops of buildings shall be designed to withstand a wind-
ot less than 30 lb per sq ft of surface.

4. Stresses †

king Stresses. In proportioning structural steel for stresses due
TED DEAD AND LIVE LOADS together with IMPACT, the working stresses

page 1053.
variations from these values, see Table XVIII, page 618, and Table I,

in pounds per square inch of sectional area shall be not more than the fo
lowing:

	lb pe sq i
Tension, net section, rolled steel	16 0
Direct compression, rolled steel and steel castings	16 0
Bending on extreme fibers of rolled shapes, built sections, girders, and steel castings, net section	16 0
Bending, on extreme fibers of pins	24 0
Shear, on shop-rivets and pins	12 0
Shear, on field-rivets	10 0
Shear, on bolts	9 0
Shear, average, on webs of plate girders and rolled beams, gross section	10 0
Bearing pressure, on shop-rivets and pins	24 0
Bearing, on field-rivets	20 0
Bearing, on bolts	18 0
Tension, in rivets	7 0
Tension, in field-bolts (not anchor-bolts)	9 0
Axial compression, on gross section of columns and struts	16 000 − 70
where l is the effective length of the member, in inches, and r is the least radius of gyration of section, in inches, with a maximum of	13 0

(47) For COMBINED STRESSES due to wind and other loads the unit stresses
Paragraph (46) may be increased 50%, except for Paragraph (44), provid
the section thus obtained is not less than that required if wind-forces a
neglected.

(48) When the laterally unsupported length, l, of the compression-flange
beams and girders exceeds 12 times its width, b, the UNIT STRESS IN THE CO
PRESSION-FLANGE, shall not exceed $19\,000 - 250l/b$.

(49) COUNTERSUNK RIVETS in plates of thickness equal to or greater th
one half the diameter of rivet shall be assumed to have three fourths the value
rivets with full heads. In plates of thickness less than one half the diamet
of rivet their values shall be taken as three eighths that of full-headed rive
RIVETS WITH FLATTENED HEADS of height not less than ⅜ in, or one half the dia
eter of the rivet for ⅝-in rivets and less, may be assumed to have the value
corresponding rivets with full heads. Rivets with heads flattened to less th
these heights shall have countersunk holes and be regarded as countersu
rivets.

(50) The allowable pressure of COLUMN-BASES and BEARING-PLATES
masonry shall not exceed, in pounds per square inch, the following. (See, al
pages 265 to 267, and 441.)

	lb p sq
On brickwork, cement mortar	4
On brickwork, lime mortar	1
On Portland-cement concrete, 1 : 2 : 4 mixture	5
On Portland-cement concrete, 1 : 3 : 5 mixture	3
On rubble masonry, cement mortar	4
On rubble masonry, lime mortar	1
On first-class dimension sandstone	4
On first-class limestone	5
On first-class granite	6

5. Design

ieneral Design-Requirements. TRUSSES shall be riveted structures. -MEMBERS as well as COMPRESSION-MEMBERS shall be composed of rolled · built-up sections. Flat bars with riveted ends shall not be used.

n calculating TENSION-MEMBERS, net sections shall be used. The diam- ivet-holes shall be assumed to be ⅛ in larger than the nominal size of In single angles connected by one leg, the net area of the connected ne half that of the outstanding leg shall be considered effective.

he NOMINAL SIZES OF RIVETS shall be used in calculations of their values.

ı proportioning COLUMNS provision shall be made for eccentric loading.

OLUMNS AND STRUTS with direct loads of 40 000 lb or less, when ıall have the entire load transmitted through splice-plates.

OLUMN-SPLICES shall be designed to resist the bending-stresses, and to columns practically continuous for their whole length.

embers subject to REVERSAL OF STRESS from moving loads shall be ıed for the stress requiring the larger section, but their connections roportioned for the larger stress plus one half the smaller.

IE EFFECTIVE LENGTH OF MAIN COMPRESSION-MEMBERS shall not exceed their least radius of gyration, and for secondary members and lateral 60 times their least radius of gyration. Any portion of the cross- a compression-member may be neglected in computing the radius of provided that portion is neglected in the design of the member.

HEEL-LOADS OF CRANES shall be assumed to be distributed on the top runway girders over a distance equal to the depth of the girder, with a of 30 in.

ATE GIRDERS shall be proportioned either by the moment of inertia of ection, or upon the assumption that the bending-stresses are resisted nges concentrated at their centers of gravity, and that the shear is ' the web. When the second method is used one eighth of the gross the web, if properly spliced, may be used as flange-section.

EB-PLATES OF GIRDERS shall have a thickness of not less than 1/160 of ported distance between flange-angles.

ANGE-PLATES OF GIRDERS shall be limited in width, so as to extend han 6 in beyond the outer line of rivets connecting them to the angles.

EB-STIFFENERS, in pairs, shall be placed over bearings, at points of ed loadings and at intermediate points, usually not farther apart than th of the girder, when the thickness of the web is less than 1/60 of the d distance between flange-angles.

FFENERS under concentrated loads and over bearings shall be designed , with a length equal to one-half the depth of the girder, and shall h rivets to properly transmit the shear. When loads are transmitted e bearing of stiffeners, the bearing value may be assumed at 24 000 ı of section, excluding the area of the chamfered portion over fillets gles.

DEPTH OF GIRDERS AND ROLLED BEAMS in floors shall be not less than span, and if used as roof-purlins shall be not less than 1/32 of the span. loors subject to shocks and vibrations the depth shall be limited to pan.

EL PURLINS shall be single rolled shapes, plate girders or lattice

(67) Lateral, longitudinal, and transverse bracing in all structures sh preferably be composed of rigid members, and shall be designed to withst wind and other lateral forces when building is in process of erection as well after erection.

(68) Wind-bracing shall be provided for tall buildings by making the co nection-joint between girders and columns sufficient for the bending due to si pressure as well as for the vertical load; or diagonal bracing shall be plac between columns, proportioned to transfer the shear of the side pressure to t footings.

(69) No steel in any structural member subject to stress shall be less than in thick, except the webs of rolled beams and channels. Steel subject to t action of harmful gases or severe atmospheric conditions shall be not less th $\frac{5}{16}$ in thick.

6. Details

(70) **General Detail Requirements.** Details throughout shall confor to first-class standard practice.

(71) No connection except lattice-bars shall have less than two rivets, prefe ably three, for better handling in fabrication.

(72) In cases where it is necessary to carry loads subject to shock by bolts tension, check-nuts shall be used. When bolts go through beveled flang beveled washers to match shall be used so that head and nut are parallel. I general, rivets and bolts in tension shall be avoided as far as practicable.

(73) Abutting Joints in compression-members faced for bearing shall spliced sufficiently to hold the connecting members accurately in place.

(74) When two or more rolled beams are used to form a girder, they shall connected by bolts and separators at intervals of not more than 6 ft. A beams having a depth of 12 in and more shall have at least two bolts to ea separator.

(75) The minimum distance between centers of rivet-holes shall be thr diameters of the rivet, and the maximum distance in the line of stress eight dia eters.

(76) The minimum distance from the center of any rivet-hole to sheared edge shall be $1\frac{1}{2}$ in for $\frac{7}{8}$-in rivets, $1\frac{1}{4}$ in for $\frac{3}{4}$-in rivets, $1\frac{1}{8}$ in f $\frac{5}{8}$-in rivets, and 1 in for $\frac{1}{2}$-in rivets; and to a rolled edge, $1\frac{1}{4}$, $1\frac{1}{8}$, 1, and $\frac{7}{8}$ i respectively.

(77) The maximum distance from the center of any rivet-hole to an edge shall be eight times the thickness of the plate.

(78) The pitch of rivets at the ends of built compression-members sh not exceed four diameters of the rivets for a length equal to one-and-one-ha times the maximum width of the member.

(79) The latticing of compression-members shall be proportioned to resi a shearing-stress equal to 2% of the direct stress. Tie-plates shall be provid at each end and at intermediate points where latticing is interrupted. In ma members carrying calculated stresses, the end tie-plates shall have a length n less than the distance between the lines of rivets connecting them to the flang and intermediate ones not less than half this distance. Their thickness shall not less than $\frac{1}{50}$ of the same distance.

7. Workmanship

(80) **General Requirements.** All workmanship shall be first-class in eve respect.

laterial shall be thoroughly STRAIGHTENED before being worked, by that will not injure it.

SHEARING shall be done accurately, and all portions of the work exposed ieatly finished.

BUTTING SURFACES OF COMPRESSION-MEMBERS, except where joints are ced, shall be planed to an even bearing so as to give close contact it.

UNCHING shall be done accurately, but occasional inaccuracies in matches may be corrected with a reamer. The diameter of the punch shall re than 1/16 in larger, nor that of the die 1/8 in larger than the diameter et. Rivets shall be driven by pressure-tools wherever possible.

OLES IN MATERIAL of same thickness as diameter of punch may be ull size.

EB-STIFFENERS OF PLATE GIRDERS under concentrated loads shall have nilled.

8. Painting

neral Painting Requirements. Cast iron need not be painted at Steelwork for foundations to be entirely embedded in concrete shall ited, but must be free of dirt, grease, or other matter which would impair f the concrete. Other steelwork shall be thoroughly cleaned and given f paint before shipment. One coat shall be given to surfaces that are e after being riveted together.

ichine-finished surfaces shall be coated with white lead and tallow ment.

er erection all structural metalwork shall be cleaned of dirt and rust ne coat of paint of a color or shade different from that of the shop-coat.

painting at the shop and site shall be done by hand when the surface l is perfectly dry. Painting shall not be done in freezing weather.

nt shall be a good quality of red lead or graphite, ground in pure lin- their equivalent.

9. Inspection

neral Requirements. All inspection and tests shall be made at the expense of the purchaser.

iaterial is tested at the mills, the necessary number of test-pieces and testing-machine shall be furnished free of charge by the steel-con-

purchaser or his representative shall have free access at all times where material is rolled and to the shops where it is fabricated. In for his needs he shall be given dates of mill and shop-operations ed with complete working drawings.

10. Erection

eral Requirements. The structural steel and iron, except anchor- intels, and material not connected with the main frame of the struc- e erected by the steel-contractor on foundations furnished by the

shall be taken that all steelwork is level and plumb before bolting or

(97) Proper provision shall be made for resisting stresses due to erection operations.

(98) In general, field-connections shall be riveted, but connections of the following classes may be bolted:

(*a*) Light subordinate framing, such as purlins, monitor and skylight-framin girts, platforms, stair-framing, partitions, ceilings, and penthouses;

(*b*) Ordinary framing of beams to beams, and beams to girders;

(*c*) Connections not subject to direct shearing-stress.

All connections, however, affected by loads that cause undue vibration, sh be riveted. One-story buildings, not subjected to excessive wind-pressure not supporting heavy concentrated loads, shafting, or moving loads, may bolted throughout. The threaded part of a bolt shall not be so long that t bearing value of the unthreaded portion is reduced to less than the sheari value of the bolt. Washers shall be used under nuts wherever needed.

(99) Drift-pins shall be used only to bring parts together. Unfair holes sh be made to match by reaming.

(100) After finishing the work the erector shall remove his equipment and rubbish resulting from his operations.

DATA ON STRUCTURAL STEEL *

Estimating the Cost of Structural Steel for Buildings

Structural steel for buildings is commonly made up of I beams, chann angles, Z bars and plates, which may be used as single beams or braces, or bu into riveted girders, columns, or trusses. The Z bars are now seldom used columns or other structural work in buildings. The cost of the completed ste work is made up of the following items:

(1) Cost of the plain steel at the mill, plus freight and dealers' profits.

(2) Extras for cutting, punching, fitting and assembling into girders, colum or trusses.

(3) Cost of the fittings, such as connection-angles, gusset-plates, etc.

(4) Shop-painting.

(5) Cost of erection at the building.

(6) Painting after erection.

Base-Price of Steel. For orders of any considerable size, the cost of pl steel is based on the price at the mills plus the freight to the point of deliver

The BASE-PRICE, free on board cars at Pittsburgh, Pa. (1920), is ab $2.45 per 100 lb for I beams and channels 15 in and less, and for angles zees from 3 to 6 in.

I beams over 15 in, cost 10 cts per 100 lb extra, and tees over 3 in, 5 cts ex

For angles, channels and zees under 3 in, the base is $2.45 at Pittsburgh.

For angles, over 6 in, $2.45 + $0.10.†

For H beams, $2.45 + $0.10.

For deck beams and bulb angles, $2.45 + $0.30. ‡

For corrugated and checkered plates, $2.65 + $1.75.§

For plates, structural, the base is $2.65.

* Valuable data was contributed for this section by Associate Editor, Robins Flem

† $2.45 + $0.10 means a base-price of $2.45 and an extra $0.10.

‡ $2.45 + $0.30 means a base-price of $2.45 and an extra of $0.30.

§ 2.65 + $1.75 means a base-price of $2.65 and an extra of $1.75; the same with $ + $0.15, etc. Corrugated steel, painted, is usually quoted at a base-price plus an e for painting. At present (1920) it is $4.25 + $0.25.

ates, flange, the base is $2.65 + $0.15.*
orrugated steel, painted, No. 22, $4.25 + $0.25.*
orrugated steel, galvanized, No. 22, $5.30.
eel sheets, black, Nos. 10 and 11, $4.00.
eel sheets, galvanized, Nos. 10 and 11, $4.70.
eel sheets, black, No. 22, $4.20.
eel sheets, galvanized, No. 22, $5.25.
r-iron, the base is $4.50.
vets, $4.50.
eel bars, $2.35.

t-Rates (March, 1920) in car-load lots are:

gh to Albany, N. Y.	27.0 cts
to Baltimore	23.0 cts
to Boston	29.5 cts
to Buffalo, N. Y.	21.0 cts
to Chicago	27.0 cts
to Cincinnati	23.5 cts
to Cleveland	17.0 cts
to Columbus, O.	20.0 cts
to Denver	99.0 cts
h to Louisville	26.5 cts
to New York	27.0 cts
to Norfolk, Va	31.5 cts
to Philadelphia	25.0 cts
to Richmond, Va.	30.0 cts
to Rochester, N. Y.	21.0 cts
to St. Louis	34.0 cts
to Washington, D. C.	24.0 cts

unt of the expense of carrying beams in stock, local dealers usually n ½ to 1½ ct a pound, extra, on orders supplied from stock.†

rd Classification of Extras. These lists are for STEEL BARS AND APES, and the extras are added ,to the BASE-PRICES for each 100 This standard classification was adopted June 15, 1919, by the teel Company.

Specification and Inspection

ial, subject to United States Navy Department specifications edium or soft steel	$0.10
e hull-steel (except rivet-rods) subject to United States Navy tment specifications	1.00

for other than mill-inspection, such as Lloyd's or American Bureau , for buyer's account.

Quantity-Differentials

fications for less than 2 000 lb of a size will be subject to the fol- is, the total weight of a size ordered to determine the extra, regard- h and regardless of exact quantity actually shipped:

$1.75 means a base-price of $2.65 and an extra of $1.75; the same with , etc. Corrugated steel, painted, is usually quoted at a base-price plus painting. At present (1920) it is $4.25 + $0.25.
t (1920) a war tax of 3% is to be added to the rates given.

Quantities less than 2 000 lb, but not less than 1 000 lb..................
Quantities less than 1 000 lb..

Straightening

Machine-straightening...

Machine-Cutting to Specified Lengths, Rounds and Squares, 1½ Inches ... Larger

Machine-cutting to lengths over 48 in.......................................
Machine-cutting to lengths over 24 in to 48 in, inclusive..............
Machine-cutting to lengths over 12 in to 24 in, inclusive..............
Machine-cutting to lengths of 12 in and less, extra will be furnished on application, but will not be less than...........................

The above extras apply only to .50 per cent carbon and under. Extras ... machine-cutting over .50 per cent carbon will be furnished on application.

Extras for machine-cutting Rounds and Squares under 1½ in, Flats, ... will be furnished on application.

Cutting to Specified Lengths, Other than Machine-Cutting

Cutting to lengths of 60 in and over...............................No ...
Cutting to lengths over 48 in to 59 in, inclusive.......................
Cutting to lengths over 24 in to 48 in, inclusive.......................
Cutting to lengths over 12 in to 24 in, inclusive.......................
Cutting to lengths of 12 in and less, extra will be furnished on application, but will not be less than......................................

Cost of Erecting. For erecting ordinary beams and columns in build... having masonry walls the cost of erection should not exceed $20 per ton ... there are bolted connections, and it will sometimes be as low as $13 per ton. ... erecting the steelwork of skeleton buildings having riveted connections ... customary to allow $18 per ton.

Cost of Painting. The usual charge for shop-painting is about $3 ... ton, but if done in accordance with the specification on page 1203 it would ... this amount. For painting one additional coat after erection, allow about ... per ton.

Roof-Trusses. In lots of at least six, the shop-cost of ordinary roof-tr... in which the ends of the members are cut off at right-angles is about as follo... Trusses weighing 1 000 lb each, from $2.00 to $3.50 per 100 lb; trusses weigh... 1 500 lb each, from $2.00 to $2.50 per 100 lb; trusses weighing 2 500 lb ... from $1.50 to $2.50 per 100 lb; and trusses weighing from 3 500 to 7 50... from $1.25 to $2.00 per 100 lb. Pin-connected trusses cost from 10 to 30 c... 100 lb more than riveted trusses.*

Steel Mill-Buildings. The average shop-cost for the frames of steel ... buildings, including draughting, is about $40 per ton, and the cost of erec... from $20 to $35 per ton.*

Cost of Drafting. Details for church and court-house roofs having ... and valleys cost from $10 to $20 per ton; details for ordinary mill-building... from $6 to $12 per ton. The cost of making shop-drawings varies greatly ... the character of the construction of the buildings, and with the accuracy o...

* If there is little duplication or parts of if manual labor enters into the fabrica... any great extent the costs given will be increased.

's drawings. The average costs per ton of steel, for making shop- are about as follows:

tire skeleton construction, in which the loads are all carried to the undations by the steel columns, $4.00.
e interior parts which are supported on steel columns, when the outside lls carry the floor-loads and their own weight, $3.50.
e interior parts which are supported on cast-iron columns, when the tside walls carry the floor-loads and their own weight, $2.50.
istruction without columns, and in which the floor-beams rest on ma- ry walls, $2.50.
ldings in which roof-trusses supported by columns comprise the greater t of the construction, $7.00.
ldings in which roof-trusses on masonry walls comprise the greater t of the construction, $4.00.
l-buildings, average, $9.00.
iufacturing or shop-buildings, with flat roofs, and one story in height, o.
rations, additions, remodeling, which require measurements before ils and shop-drawings can be made, $12.00.*

imate Estimates of the Weight of Steel in Buildings. Accord- G. Tyrell,† the weight of steel in any proposed new building may be imated from the following data, which is a fair average for buildings leven stories high, designed according to the Building Laws of the ston:

	Per sq ft of floor
nent-houses and hotels, with outside frame	14 lb
nent-houses, without outside frame	9 lb
uildings, with outside frame	23 lb
uildings, without outside frame	15 lb
uses, with outside frame	28 lb
uses, without outside frame	18 lb

ings higher than eleven stories, the weight of floors will increase in rtion to the number of stories, while the weight of columns will e rapidly.
pproximate weight of roof-trusses, see Chapter XXVII, pages 1050

Weights of Steel in Buildings ‡

ffecting the Weights of Steel Structures are many and varied. er square foot of area or per cubic foot of volume of a structure should not be assumed as the weight of a proposed structure conditions which govern the one are found in the other. Munici- codes specify floor-loads and these vary greatly. The prescribed , working stresses and column-loads, affect the weight. The features to be followed also play an important part. In mill- weight is affected by the kind of roofing and siding used, capacity

f $12.00 includes the cost of taking measurements. This generally has to contractor.
Structural Steel, in Architects & Builders' Magazine, Jan., 1903.
by Robins Fleming.

of cranes, spacing of trusses and columns, shafting, special loadings and allowable minimum thickness of metal.

Weights of Steel in a Number of Structures are given in the follow table and notes. The caution regarding such weights being taken as pre dents should be emphasized. The office-building heading the list is Equitable building, the largest office-building in the world.

	Average dimensions in feet			Tiers of beams	Weight in pounds per square foot of framed area	Weight pounds cubic f of volum
	Width	Length	Height			
Office-buildings	159	308	542	41	37.00	2.55
	43	79	217	17	26.10	2.2[illegible]
	90	90	258	22	28.92	2.4[illegible]
	81	139	225	19	21.90	1.8[illegible]
	43	104	149	13	33.40	2.9[illegible]
	48	111	115	9	17.34	1.51
Hotels	97	119	244	20	26.02	1.92
	84	143	270	24	26.95	2.39
	96	101	232	18	25.40	2.0[illegible]
	108	120	115	9	14.00	1.0[illegible]
Department-stores	133	219	150	11	23.87	1.7[illegible]
	62	211	130	8	29.44	1.8[illegible]
	103	132	89	7	18.30	1.4[illegible]

	88	121	121	9	20.60	1.8[illegible]
	145	357	102	7	30.80	2.1[illegible]
	58	72	52	3	31.35	1.8[illegible]

Among prominent New York buildings the 55-story Woolworth Bui with a ground-area of 31 000 sq ft weighs 3.0 lb per cu ft.; the 39-story Ban Trust Building with an area of 9 000 sq ft, 3.1 lb.; the 25-story Muni Building with an area of 42 700 sq ft, 3.6 lb; the 25-story Hotel McA with an area of 31 000 sq ft, 2.0 lb. The 10-story Curtis Building of Ph delphia with an area of 94 000 sq ft weighs 3.0 lb. The structural ste four buildings of Pittsburgh, the Arrott, the Farmers' Bank, the Empire the Oliver, is quoted as weighing respectively 2.8, 2.3, 2.1 and 1.8 lb per c For buildings of from 8 to 12 stories in which the exterior walls are carrie steel framing the weight per cubic foot of volume may be assumed at 1 for office-buildings and 1.5 for hotels.

Armories. The three-hinged arches with roof-framing of an armor Brooklyn, 191 by 300 ft in area, weighs 15.5 lb per sq ft of ground area. armory in Buffalo, 233 by 335 ft, weighs 18.3 lb. The steelwork of the K bridge Armory, New York City, 289 by 590 ft, said to cover the largest hall in the world, weighs about 90 lb per sq ft, of which one half is roof one half floor and miscellaneous framing.

Boiler-Shops. Sizes and weights per square foot of a few boiler-shop as follows: 167 by 336 ft, three aisles, floor in center and cranes in outer concrete roof and sides, steel purlins and girts, 23.9 lb; 124 by 300 ft,

h 15, 25 and 50-ton cranes respectively, steel purlins and brick walls :olumns, 36 lb; 74 by 160 ft, 10-ton crane in center aisle, single beams aisles to carry roof, galvanized corrugated-steel covering and siding, 85 by 140 ft, two aisles, one with crane, 20.8 lb; 94 by 97 ft, two aisles, :rane, 26.3 lb.

ırns. The steel roof-trusses and bracing of a car-barn 100 by 154 ft, ins, brick walls, weighs 6.2 lb per sq ft. Another car-barn, 44 by 270 ft. l-steel roof, and sides on steel purlins and girts, 9.15 lb. Another, 4 ft, four aisles, concrete roof on steel purlins, 11.8 lb.

t-Plants. Four cement-plants with ground-areas of 58 000, 73 000, l 128 000 sq ft respectively, weigh respectively, 23.6, 22.0, 23.5, and These weights are the averages of the buildings that usually form a nt. The individual buildings vary from 10 lb for an engine-room for a clinker-grinding room.

ınkers. The weights of six coal-bunkers of the suspended type and ities of from 350 to 1 000 tons, range from 128 to 234 lb per ton of he average being 204 lb. A system of rectangular pockets to store (10 ft 6 in from ground to valves) weighs 158.3 lb per ton of capacity. the weights of supports but not of roofs are included. A 35 by 70-ft pported on plate girders with a capacity of 1 000 tons weighs 240 lb capacity, including the roof-trusses that carried the conveyor.

ıops. The steel framing for the roof of a forge-shop 83 by 126 ft, ımns and no cranes, covered with corrugated steel on steel purlins, lb per sq ft of ground-area. A forge-shop 220 by 240 ft, four aisles, rane-runways, composition roofing, concrete sides, steel purlins and 24.6 lb. A forge-shop 110 by 425 ft for heavy work, 47 ft 6 in to rd, two aisles each with a 50-ton crane, tile roof, glass and brick 40 lb.

s. A pipe-foundry, 50 by 150 ft, slate covering, wooden purlins, 15-ton crane, weighs 11.35 lb per sq ft. A similar one for the ny, 45 by 82 ft, with a 30-ton crane, weighs 17.23 lb. A foundry, , one center aisle, with light crane, lean-to each side, corrugated-d sides, weighs 14.8 lb. A foundry, 150 by 290 ft, for a pump-ur aisles with 20-ton crane in one aisle, wooden purlins, two charging-floors of concrete on steel beams, weighs 13.9 lb. A by 252 ft, equipped for heavy work, 60-ft center aisle, two side charging-floor, storage-platform, weighs 38.9 lb.

Shops. A machine-shop, 90 by 328 ft, for heavy work, one o ft wide with 25-ton crane, each side aisle 25 ft wide with gallery-on crane underneath, tile roof on steel purlins, brick and glass 43 lb per sq ft of ground-area. A two-story machine-shop, three aisles, light cranes in lower story, composition roof, steel ete sides, weighs 35.15 lb. A one-story building, 75 by 300 ft, om chord, shafting, corrugated-steel roofing and siding, weighs ther one-story building, 70 by 100 ft, 18 ft to bottom chord, rete roof on trusses 10 ft apart, no purlins, weighs 13.88 lb. In steel framing for the Hy-rib sides of this building weighs 3.44 lb ertical surface. A machine-shop, 116 by 252 ft, 60 ft center aisle, o-ton-crane runway and lower 25-ton-crane runway, two side le with traveling jib-cranes, weighs 33 lb.

lls. A rolling-mill, 93 by 186 ft, corrugated-steel roof and 7.6 lb per sq ft. Another, 170 by 384 ft, two aisles each with

5-ton cranes, saw-tooth roof-trusses on longitudinal girders, concrete slab steel purlins, brick walls between columns, weighs 17.5 lb. A similar buil for shop-purposes weighs 18.62 lb.

Paper-Mills. The entire structural steel for three paper-mills we respectively 18.4, 20.6 and 21.4 lb per sq ft of area. All roof-trusses ar the flat type, spaced 8 ft apart in the first and third, and 16 ft in the second

Power-Houses. A power-house, 44 by 186 ft, 49 ft to bottom chord, ton crane, tile roof on steel purlins, brick walls between columns, weighs per sq ft. Another, 53 by 270 ft, 33 ft to bottom chord, 20-ton crane, tile on steel purlins, brick walls and sash between columns, weighs 39.6 lb. Anot 120 by 96 ft, one aisle for boiler-room and one with 10-ton crane for eng room, steel purlins for concrete roof-covering, brick walls between colu weighs 17.8 lb.

Train-Sheds. The train-shed of the Pennsylvania Railroad in P delphia, 598 ft long and with arches 300 ft 8 in from center to center of weighs 39.1 lb per sq ft of ground-area; the train-shed of the same railroa Jersey City, 777 ft long and with arches 252 ft 8 in, weighs 27.9 lb; and th the Philadelphia & Reading Railroad in Philadelphia, 506 ft 8 in long with arches 259 ft 8 in, weighs 31.5 lb. The train-shed, 390 by 815 ft, of Central Railroad of New Jersey in Jersey City, is a series of concrete and umbrellas, of the Bush-type. The structural steel weighs 17 lb per sq ft of a

Three Industrial Plants. In one of the plants of a great industrial poration a two-story shop, 51 by 380 ft, weighs 28 lb per sq ft of ground- a three-story shop, 80 by 420 ft, 37.9 lb; a three-story shop, 80 by 300 ft, 46. a three-story shop, 80 by 630 ft, 67.5 lb; a four-story shop, 77 by 14 66.6 lb; a foundry, 121 by 150 ft, 40.5 lb. In another plant of the same poration, a three-story machine-shop, 80 by 510 ft, weighs 84.3 lb; a five- office-building, 49 by 243 ft, 70.3 lb; a power-house, 55 by 120 ft, 37. a blacksmith-shop, 81 by 200 ft, 15.6 lb. In a plant of another corpora a boiler-house, 50 by 94 ft, weighs 23.3 lb; a furnace-building, 60 by 16 25.1 lb; a rolling-mill, 80 by 80 ft, 24.4 ft; a rod-mill, 243 by 220 ft, 28.1

Cost of Merchant Steel. The cost of merchant iron and steel of all k is based on a certain size of each particular shape, which is taken as the and the price of all other sizes is figured at a certain extra rate above the according to a standard CARD OF MILL-EXTRAS. The BASE-PRICE may tuate and be changed without notice, but the extras remain constant, and the same in all localities. The following tables include the standard classific of extras on iron and steel bars.

Standard Classification* of Extras on Iron and Steel Bars
Adopted July 15, 1919.

Rounds and squares

Sizes	Extra per 100 lb	Sizes	Extra per 100 lb
6 in	Base	7/32 in	$1.00
6 in	$0.05	3/16 in	1.25
in	0.10	3 1/8 to 3 9/16 in	0.075
in	0.20	3 5/8 to 4 1/16 in	0.125
in	0.25	4 1/8 to 4 9/16 in	0.15
in	0.30	4 5/8 to 5 1/16 in	0.20
in	0.35	5 1/8 to 5 9/16 in	0.25
in	0.40	5 5/8 to 6 1/16 in	0.375
in	0.50	6 1/8 to 6 1/16 in	0.50
in	0.75	6 5/8 to 7 1/4 in	0.625

Flats

Sizes	Extra per 100 lb
in × 1 3/8 to 1 in	Base
in × 1/4 to 5/16 in	$0.10
5/16 in × 3/8 to 3/4 in	0.20
/16 in × 1/4 to 5/16 in	0.25
in × 3/8 to 1/2 in	0.25
in × 1/4 to 5/16 in	0.35
in × 3/8 to 7/16 in	0.50
in × 1/4 to 5/16 in	0.60
in × 3/8 in	0.70
in × 1/4 to 5/16 in	0.80
in × 1/4 to 5/16 in	1.00
in × 1 1/16 to 1 3/16 in	0.05
in × 1 1/4 to 1 1/2 in	0.10
in × 1 5/8 to 2 3/4 in	0.15
in × 3 to 4 in	0.20

Standard Classification † of Angles, Channels and Tees

Angles

Sizes	Extra per 100 lb
and wider, but under 3 in × 3/16 in and over	$0.10
and wider, but under 3 in × 1/8 in	0.15
1/4 × 1 1/4 in × 3/16 in and over	0.15
1/4 × 1 1/4 in × 1/8 in	0.20
in × 3/16 in	0.20
in × 1/8 in	0.25
in × 3/16 in	0.25
in × 1/8 in	0.30
in × 1/8 in	1.10
in × 3/32 in	1.30

⅝ in × 3/32 in	1.40
½ in × 7/64 in and over	1.80
½ in × 5/64 in	2.00

Tees

Sizes	Extra pe 100 lb
1½ × 1½ in and wider, but under 3 in × 3/16 in and over	$0.20
1 × 1 to 1¼ × 1¼ in × 3/16 in and over	0.40
1 × 1 to 1¼ × 1¼ in × ⅛ in	0.50
⅞ × ⅞ in × 3/16 in	0.50
⅞ × ⅞ in × ⅛ in	0.60
¾ × ¾ in × 3/16 in	0.60
¾ × ¾ in × ⅛ in	0.70
⅝ × ⅝ in × ⅛ in	1.30
½ × ½ in × ⅛ in	1.80
Unequal-leg tees are subject to special prices, which will be furnished on application.	

* Intermediate sizes take the next higher extra.

The base for car-load lots for any city may be obtained by adding the frei rates given on page 1524 to the base prevailing at the mills.

CHAPTER XXXI

)MICAL AND VAULTED STRUCTURES *

By

EDWARD F. RIES

CONSULTING ENGINEER, SAN ANTONIO, TEXAS

1. Domes *

cation: Domical structures may be considered under two main (1) Smooth-shell domes, and (2) ribbed domes. The first division be divided into (a) domes with shells of uniform thickness, and (b) h shells of uniformly varying thickness. The materials of con- f division (1) are brick, stone, concrete, and tile; and of division (2), rete, and wood. A dome may be constructed with or without a ›r with or without an OCCULUS or EYE; and in the case of ribbed r may have either circular or polygonal bases.

(1) Smooth-Shell Domes

ical Principles. Under this heading are considered both (a) domes of uniform thickness, and (b) domes with shells of uniformly vary- ss, and also domes with or without lanterns and eyes. A dome tapers toward the top is the more stable dome. It is evident that urt, or crown, tends to fall in and thereby push out the lower por- the lighter the upper part is in relation to the lower part, the the dome. The exact actions of the INTERNAL STRESSES in a dome o determine, but a very practical solution can, however, be developed ng that the stresses are parallel to a surface midway between the ner surfaces of the dome.

Analysis. A dome may be imagined to consist of a number of ngs of decreasing diameter, each one laid on top of another. er part tends to fall in and push out the lower part, there must be a contract each ring in the upper part and to expand each ring in the That is, there must be END-COMPRESSION on all stones (imaginary oncrete) of the upper part, and END-TENSION on all stones of the The dividing line or horizontal joint between these upper and lower dome is called the JOINT OF RUPTURE. The angle made by the ıre with the vertical (center of dome as apex of angle) is known CAL ANGLE. It is evident, then, that the determination of the TURE and the CRITICAL ANGLE determines also the points below s tension in the rings. By reinforcing the lower part with steel to resist this tension, the dome can be made secure. If the dome E, that is, one in which the angle the base makes with the vertical he CRITICAL ANGLE, the tension-steel must be placed at the base › resist the outward push or thrust,

* See, also, Chapters VII and VIII.

Notation and Theory (See Fig. 1):

r = mean radius of dome;
a = thickness of shell at crown;
t = thickness of shell or of ring at any point;
α = angle made with the vertical by radius to lantern-ring. Center of dome is the apex of angle. In a dome without lantern, $\alpha = 0$;
θ = angle made with the vertical by radius passing through any point in shell (in equations angles are in radians);
c = constant of variation of t with respect to arc θ;
$\frac{cr}{a}$ = a constant (based on above notation) for any dome;
ϕ = critical angle, that is, the angle made with the vertical by the joint of rupture;
w = weight of cubic unit of masonry;
V = volume of shell of complete dome above any ring;

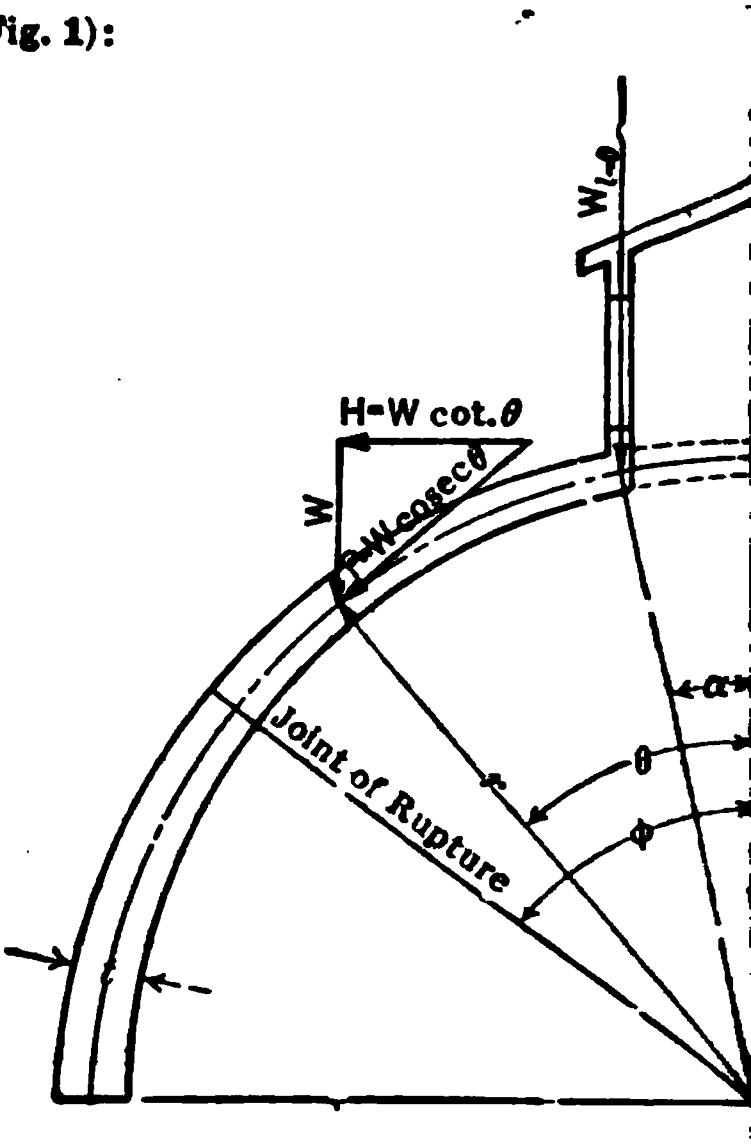

Fig. 1. Smooth-shell Concrete Dome. Analysi

$W_d = wV$ = total weight of complete shell above any ring (including the removed for eye);
W_{l-o} = weight of lantern minus weight of shell removed for occulus or (${W_{l-o}}$ may be either positive or negative);
$W = W_d + W_{l-o}$;
$n = \frac{W_{l-o}}{2\pi w a r^2}$, a constant for any dome;
P = total tangential pressure for any ring, due to lantern and shell a that ring;
U = tangential pressure per unit-length of ring;
H = total radial horizontal pressure on any ring, due to outward pus thrust of shell above that ring;
T = hoop-tension or hoop-compression in ring, due to H;

Using this analysis and notation, the following equations are developed:

Equation (1) $t = a + cr\theta$

Equation (2) $V = 2\pi r^2[a(1 - \cos\theta) + cr(\sin\theta - \theta\cos\theta)]$

Equation (3) $W_d = wV = 2\pi w a r^2\left[(1 - \cos\theta) + \frac{cr}{a}(\sin\theta - \theta\cos\theta)\right] =$

$$s = 2\pi\left[(1-\cos\theta)+\frac{cr}{a}(\sin\theta-\theta\cos\theta)\right]$$

n (4) $$P = 2\pi w a r^2\left[(n \operatorname{cosec}\theta + \operatorname{cosec}\theta - \cot\theta)+\frac{cr}{a}(1-\theta\cot\theta)\right]$$

n (5) $$U = w a r\left[\frac{n}{\sin^2\theta}+\frac{\operatorname{cosec}\theta-\cot\theta+\frac{cr}{a}(1-\theta\cot\theta)}{\sin\theta}\right]$$

$$= w a r\,(S_1+S),\quad \text{in which}$$

$$S_1 = \frac{n}{\sin^2\theta}\quad\text{and}$$

$$S = \frac{\operatorname{cosec}\theta-\cot\theta+\frac{cr}{a}(1-\theta\cot\theta)}{\sin\theta}$$

(6) $$T = \frac{H}{2\pi} = w a r^2\left[n\cot\theta+(1-\cos\theta)\cot\theta + \frac{cr}{a}(\sin\theta-\theta\cos\theta)\cot\theta\right]$$

$$= w a r^2\,(Y_1+Y),\ \text{in which}$$

$$Y_1 = n\cot\theta\quad\text{and}$$

$$Y = \left[(1-\cos\theta)\cot\theta+\frac{cr}{a}(\sin\theta-\theta\cos\theta)\cot\theta\right]$$

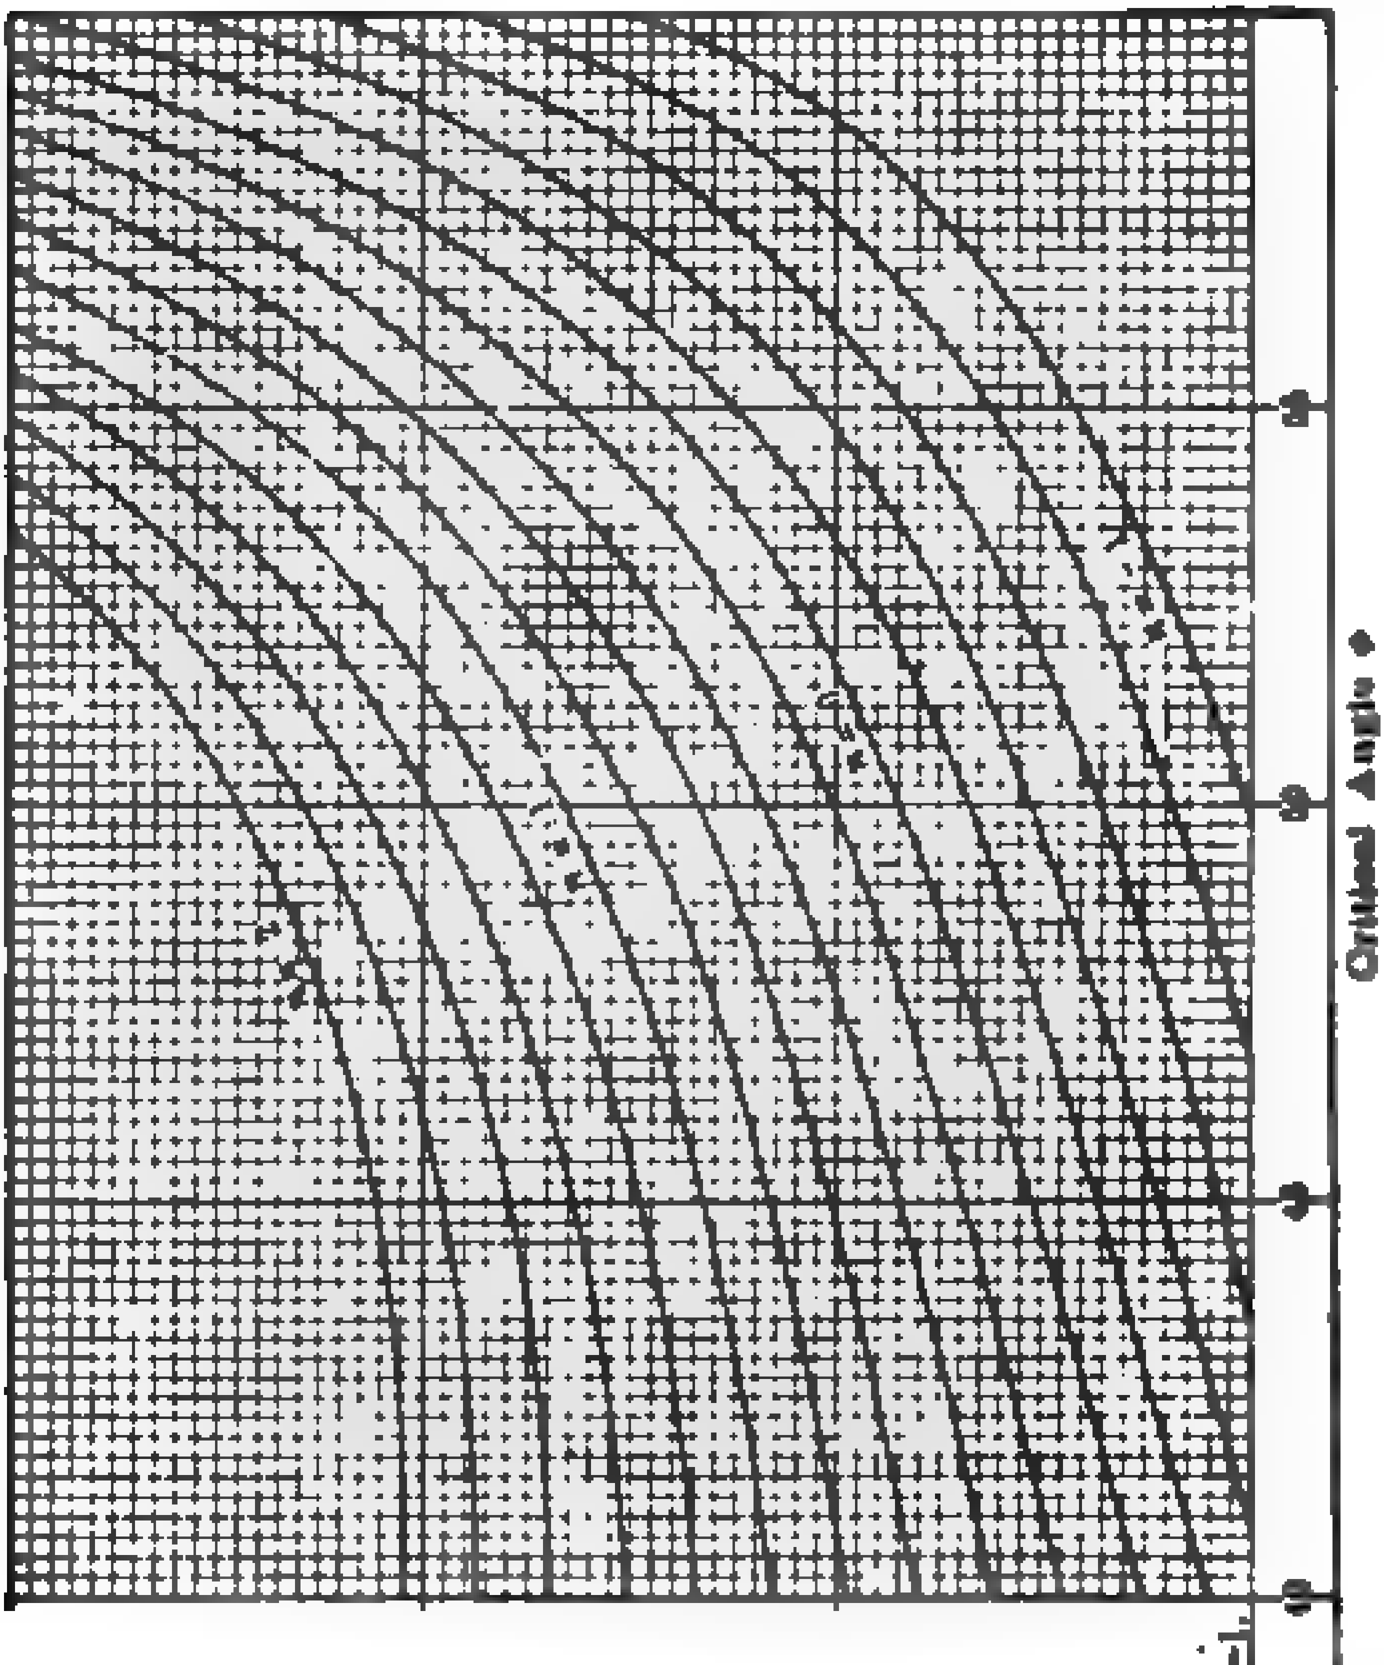
7) $$\frac{cr}{a} = \left[n\operatorname{cosec}^2\theta-\frac{\cos\theta-\sin^2\theta}{1+\cos\theta}\right]+\left[\theta\cos\theta-\frac{1-\theta\cot\theta}{\sin\theta}\right]$$

and Investigation of Smooth-Shell Circular Domes. By the use
going equations any CIRCULAR DOME can be designed or investigated.
tations, however, connected with some of these equations are long
, and are simplified by using curves plotted from the solutions
giving different values to some of their elements or factors. (See
III, and IV.)

n (7) is represented by the curves in Plate I. By the use of these
osition of the JOINT OF RUPTURE for any dome is found by inspection
ues of $\frac{cr}{a}$ and n are known. The value of $\frac{cr}{a}$ is easily determined, as c
by using Equation (1) after determining or assuming a, the thick-
rown, and t, the thickness at the base; and the value of n is found
$n = \frac{W_{l-o}}{2\pi w a r^2}$.

3) is represented by the curves in Plate II. From these curves the
shell is determined.

5) is represented by the curves in Plate III. Knowing the values
e values of S_1 and S are found by inspection, and hence U is easily



Values of $\frac{\sigma}{s}$

Plate I. Curves for Determination of Joint of Rupture of Domes. Based on Equation (

Equation (6) is represented by the curves in Plate IV. Knowing the values
n and $\frac{\sigma}{s}$, the values of Y_1 and Y are found, and T computed for any ring. Wh
n equals zero, Y_1 equals zero, and the value of T depends upon Y as given in t
lower curves. It will be noticed that Y increases as θ increases until the cri
ical angle for a dome without lantern, or eye ($n = 0$), is reached; that is, ea
successive ring increases the outward thrust, and at the CRITICAL ANGLE there
a maximum value of Y, and hence a MAXIMUM HOOP-TENSION T. After t
CRITICAL ANGLE is passed the rings are in tension, and therefore T and Y a
reduced by the tension required of the ring or masonry.

The curves also indicate that the stability of a dome with a shell of unifo

Angle θ

equired to design a SMOOTH SHELL REINFORCED CONCRETE and with a lantern of 10-ft radius, weighing 50 000 lb. The ern is to be removed, forming an eye. (Fig. 2.)

a crown-thickness, a, of 5 in, and a thickness, t, at the base

$$t = a + cr\theta, \text{ or } \frac{cr}{a} = \frac{t - a}{a\theta}$$

Angle θ

Plate III. Curves for Determination of Tangential Stress per Unit-length of De ring. Based on Equation (5)

For the dome without wind-loads or snow-loads

$$\frac{\sigma}{a} = \frac{\frac{8}{12} - \frac{5}{12}}{\left(\frac{5}{12}\right) 1.396} = 0.43$$

The angle $\alpha = \sin^{-1} \frac{10}{45} = 12° \ 50'$.

From Plate II the weight of the shell removed for the eye is

$$150 \left(\frac{5}{12}\right) (45)^2 (0.165) = 20\ 883 \text{ lb}$$

Angle θ

'urves for Determination of Hoop-tension or Hoop-compression in Dome-ring. Based on Equation (6)

$$W_{t-\theta} = 50\,000 - 20\,883 = 29\,117 \text{ lb}$$

loads and snow-loads a simple and safe method of procedure is to ›rm load over the surface of the dome, since this load can be trans- equivalent in inches of masonry and hence the same equations and A wind-load, for example, of 25 lb per sq ft, is equivalent to 2 in veighing 150 lb per cu ft. Hence the new a and t equal 7 and 10 in, Hence from Equation (1)

$$\frac{\sigma}{a} = \frac{\frac{10}{12} - \frac{7}{12}}{\left(\frac{7}{12}\right) 0.1396} = 0.307$$

and

$$n = \frac{W_{l-o}}{2\pi w a r^2} = \frac{29\,117}{2\pi(150)\left(\frac{7}{12}\right)(45)^2} = 0.026 \text{ *}$$

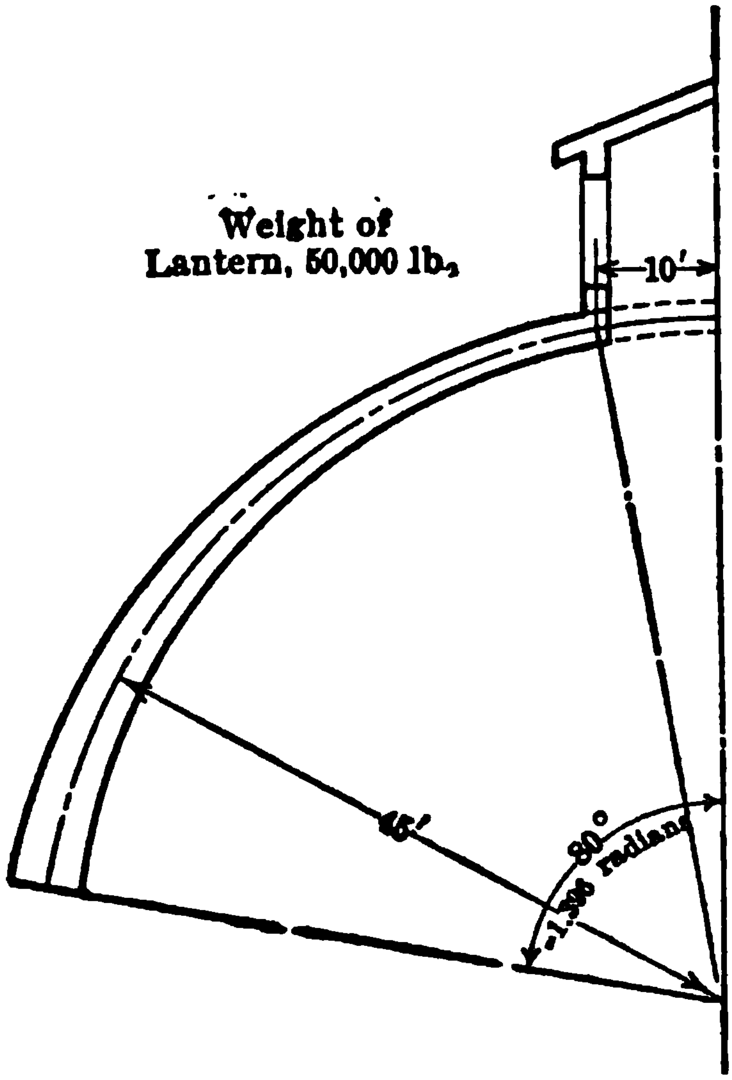

Fig. 2. Smooth-shell Concrete Dome with Lantern and Eye. See Example

From Plate I, with $\frac{cr}{a} = 0.$
and $n = 0.026$, the CRITICAL AN
is found to be 52° 35'.

From Plate IV, at the CRIT
ANGLE for the dome with sn
load and wind-load

$$T = 150\left(\frac{7}{12}\right)(45)^2(0.020 + 0.$$
$$= 65\,914 \text{ lb tension}$$

This must be resisted by
reinforcing rods. Allowing a
tensional stress of 16 000 lb
sq in in the steel, a total
$\frac{65\,914}{16\,000} = 4.12$ sq in sectional
of steel is required. At the b
($\theta = 80°$)

$$T = 150\left(\frac{7}{12}\right)(45)^2(0.005 + 0.$$
$$= 33\,843 \text{ lb}$$

The total cross-sectional are
steel in tension at the bas
$\frac{33\,843}{16\,000} = 2.12$ sq in, given by
round rods, each ¾ in in diam

The remaining required sectional area of steel, $4.12 - 2.12 = 2$ sq in,
be spaced in the lower part of the dome over an angular distance of (80° — 52°
= 27° 25' = 0.4785 radian, or $0.4785 \times 45 = 21.53$ ft up the surface of
dome.

The assumed thickness of shell at the base was 8 in, and the thickness at
lantern-ring will be, from Equation (1),

$$t = a + cr\theta = a + a\frac{cr}{a}\theta$$

or

$$5 + 5\,(0.43)(0.2239) = 5.48 \text{ in}$$

Allowing 0.2 per cent of steel cross-section, horizontally and meridionally,
SECONDARY STRESSES caused by temperature-changes and possible une
snow-loads and wind-loads, there should be $8 \times 12 \times 0.002 = 0.19$ sq in of
cross-section per running foot at the base, and $5.48 \times 12 \times 0.002 = 0.13$ s
per running foot at the lantern-ring. The spacing of the horizontal reinfo

* The snow-load on the top of the lantern is taken care of because snow-loads and w
loads over the entire dome were included, and only the actual masonry of the eye
subtracted.

ound as indicated in Fig. 3. Curve *A* gives the total amount of steel *r* for SECONDARY STRESSES above any point in the cross-section of the urve *B* gives the necessary tensional resistance, using Curve *A* as a

ram for Determination of Amount of Horizontal Steel Reinforcing in Concrete Domes

for the ordinates. Various points on the curve are easily deter- ample, for $\theta = 70°$

$$t = 5 + 5(0.43)(1.2217) = 7.63 \text{ in}$$

n of temperature-steel per foot at 70° is

$$7.63 \times 12 \times 0.002 = 0.18 \text{ sq in}$$

ection of temperature-steel above 70° is then

$$\frac{0.18 + 0.13}{2} \times (1.2217 - 0.2239)45 = 6.96 \text{ sq in}$$

cross-section (Plate IV) above 70° is

$$\frac{(150)\ (7/12)\ (45)^2(0.298 + 0.009)}{16\,000} = 0.72 \text{ sq in}$$

ermined in this manner the curves are developed. section of horizontal steel in the entire cross-section of the

$$8.45 + 2.00 = 10.45 \text{ sq in}$$

2.12 sq in of tension-steel at the base. If ½-in round rods be $\frac{10.45}{0.1963} = 54$, required in the shell. By dividing the area

below the curve (Fig. 3) into 54 parts, the distance up from the base, where eac rod should be placed, is determined. The meridional steel should be such th there will be 0.19 sq in of cross-section per foot of circumference at the bas and 0.13 sq in per foot of circumference at the lantern-ring; that is, if ½-in roun rods are used, they should be spaced $\frac{0.1963}{0.19} = 1.03$ ft at the base, and $\frac{0.1963}{0.13}$ 1.51 ft at the lantern-ring. The punching-shear at the lantern-ring is equal t

$$\frac{50\,000}{(5.48)\,(2\pi 10 \times 12)} = 12.1 \text{ lb per sq in}$$

This is well within the limit of 40 lb per sq in.

(2) Ribbed Domes

General Principles. The following discussion applies to domes of eith circular or polygonal horizontal cross-sections. All steel domes are ribb domes, and usually have from six to twenty-four ribs resting against a LANTER RING OR SPIDER at the top. The ribs may have solid webs, perforated webs, latticed webs, with angle or channel-flanges. The latticed angle-ribs are prefe able because of their lightness. The tension-rings and compression-rings m be built similar to the main ribs, and should brace the latter through rig gusset-connections. The diagonals are usually rods with turnbuckles for adjus ment. CONCRETE-RIBBED DOMES or WOODEN-RIBBED DOMES may be design according to the same general principles followed for steel domes, but the dia onals are omitted and dependence for rigidity is placed on the slab-fillin between the ribs.

The Schwedler Method for the Design of Steel Domes. W. Schwed has by simple resolution of the forces derived equations for domes, based on forms of SURFACES OF REVOLUTION. These equations are easily checked wh the forces acting through a RIB (the rib acting as a strut between the joint and through a RING at a joint are considered. The following laws may stated:

(1) The ribs are in maximum stress when the whole dome is loaded;

(2) A ring is in maximum tension when all of the dome above the ring is fu loaded, and in maximum compression when all of the dome below the ring an the ring itself is fully loaded;

(3) The DIAGONALS are not stressed when the dome is symmetrically load The diagonals in a panel are in maximum stress when the dome on one side of meridional plane passed through the center of that panel is fully loaded an the other side unloaded.

In Fig. 4 let

α_1, α_2, α_3, etc. = angles made by rib-sections with the horizontal;

β_1, β_2, β_3, etc. = angles made by diagonals with the ribs;

P_1, P_2, P_3, etc. = dead loads at ends of rib-sections;

L_1, L_2, L_3, etc. = live loads at ends of rib-sections;

D_1, D_2, D_3 etc. = stresses in rib-sections;

T_1, T_2, T_3, etc. = stresses in rings;

N_1, N_2, N_3, etc. = stresses in diagonals;

n = number of ribs.

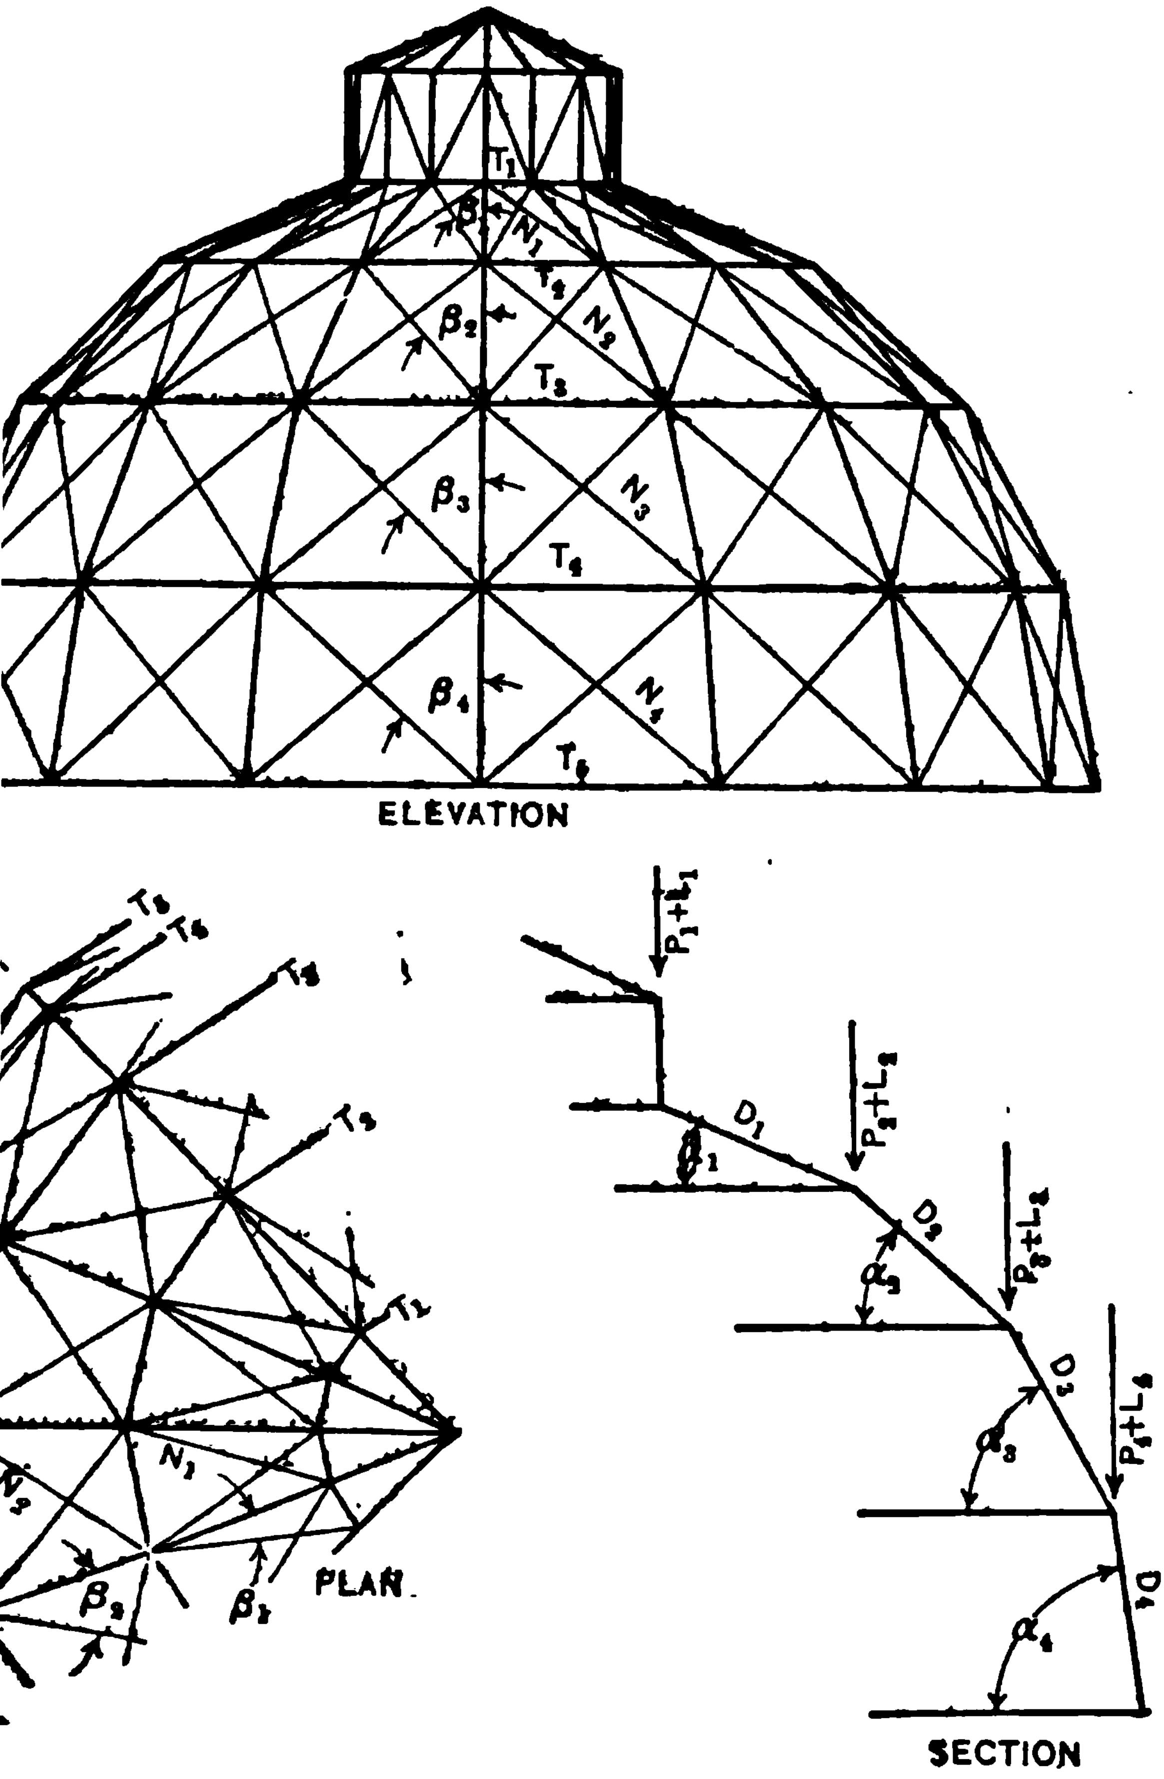

Fig. 4. Schwedler Ribbed Dome

$$D_1 = \frac{P_1 + L_1}{\sin \alpha_1} \quad D_2 = \frac{(P_1 + L_1) + (P_2 + L_2)}{\sin \alpha_2}$$

$$D_3 = \frac{(P_1 + L_1) + (P_2 + L_2) + (P_3 + L_3)}{\sin \alpha_3}, \text{ etc.}$$

$$T_1 = -\frac{(P_1 + L_1)\cot \alpha_1}{2 \sin \frac{\pi}{n}} = -\frac{D_1 \cos \alpha_1}{2 \sin \frac{\pi}{n}}$$

ult is negative the stress is compressive).

$$\text{Maximum } T_2 = \frac{(P_1 + L_1)\cot\alpha_1 - (P_1 + L_1 + P_2)\cot\alpha_2}{2\sin\frac{\pi}{n}}$$

$$\text{Minimum } T_2 = \frac{P_1\cot\alpha_1 - (P_1 + P_2 + L_2)\cot\alpha_2}{2\sin\frac{\pi}{n}}$$

$$\text{Maximum } T_3 = \frac{(P_1 + L_1 + P_2 + L_2)\cot\alpha_2 - (P_1 + L_1 + P_2 + L_2 + P_3)\cot}{2\sin\frac{\pi}{n}}$$

$$\text{Minimum } T_3 = \frac{(P_1 + P_2)\cot\alpha_2 - (P_1 + P_2 + P_3 + L_3)\cot\alpha_3}{2\sin\frac{\pi}{n}}, \text{ etc.}$$

$$N_1 = \frac{L_1}{2\sin\alpha_1\cos\beta_1} \qquad N_2 = \frac{L_1 + L_2}{2\sin\alpha_2\cos\beta_2} \qquad N_3 = \frac{L_1 + L_2 + L_3}{2\sin\alpha_3\cos\beta_3}, \text{ etc.}$$

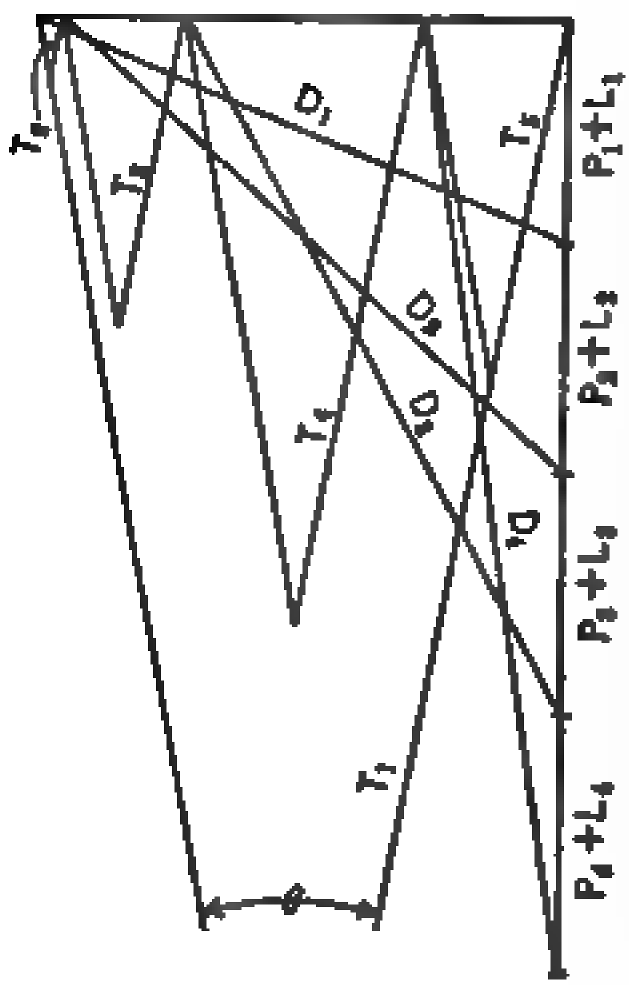

Fig. 4A. Graphical Determination of Stresses in Ribbed Domes

For the stresses in the diagonals factor 2 is introduced because Mü Breslau found, by exact anal stresses only one half as large as t determined by the simple resoluti forces. The diagonals are stressed u a wind-load, and this is resiste assuming a vertical live load equ from 20 to 30 lb per sq ft of HORIZO PROJECTION.

A GRAPHICAL METHOD, develope E. Schmidt, for determining the str D_1, D_2, D_3, T_1, T_2, T_3, etc., is show Fig. 4A.

Weights of Steel Domes. It found by Scharowsky, from calculat made for a large number of Schwe FLAT DOMES varying in span from 180 ft, that the weight of the la and steel skeleton per sq ft of proje (covered) area is

$$w = 0.0156S + 4$$

where w = pounds per square fo projected area, and S = the span, in For preliminary calculations on HEMISPHERICAL DOMES, the w found by this equation should b creased from two and a half to times.

Dome of the Horticulture Palace, San Francisco, Cal.* This is a LER HEMISPHERICAL DOME of 152-ft span, with twenty-four latticed ribs, :p, carrying a LANTERN-RING OR SPIDER at the top, and connected by eleven al rings. The lantern-ring is 6 ft in diameter, 36 in deep, with a solid l braced twice diametrically. The ribs are constructed of two 4 by 4 ι angles at the top, two 3 by 3 by 5⁄16-in angles at the bottom, and a 2½ ιy ¼-in angle single-lattice web. The dome-steel weighs about 17 lb : of projected area.

ete Ribbed Domes. In a REINFORCED-CONCRETE RIBBED DOME ber of ribs, varying from eight upward, is determined by the substruc- the size of the dome. The different steps in designing a ribbed rein- ncrete dome are: (1) the determination of the number of ribs and rings; etermination of the loading, per rib, using the required shell-thickness assumed rib-sizes and ring-sizes for preliminary calculations; (3) the f the forces acting on the ribs by the use of Schwedler's formulas; awing of the ELASTIC CURVE for the ribs; (5) the determination of the nd necessary reinforcement in the ribs, rings, and slabs; (6) the adjust- izes and loads, so as to be on the side of safety; and (7) the reworking eliminary computations for the final design. The ELASTIC CURVE vays remain in the MIDDLE HALF † OF THE RIB, and should never be y from the center of gravity of the rib-section that the maximum com- ress of 500 lb per sq in in the outer fiber of the rib is exceeded. The ient in the RIBS should be sufficient to resist the flexural stresses due ENTRICITY OF THE ELASTIC CURVE. The reinforcement in the RINGS sufficient to resist the tensile stresses, and should be as straight as ι order to avoid a sidewise stress or movement. The rings must be to resist their FLEXURE, as beams. The panel-slabs, if domical (see ιell Domes), should be reinforced for SHRINKAGE-STRESSES and TEM- STRESSES, in addition to the reinforcement for tension below the gle. If the slabs are straight they should be designed as floor-slabs, ilar methods.

.‡ It is required to build a dome (Fig. 5) with a span of 132 ft and a : 6 in. This makes the radius 85 ft. The eye is to be 12 ft in diam- outer surface of the dome is to be a domical slab on ribs, carrying a plastered ceiling forming the inner surface.

§ To obviate the necessity of building a complete domical form, rom the floor below, the decision is to build a RIBBED DOME as follows: d to build a central tower to temporarily carry the upper ends of the ast these ribs, raise them into position, cast the ring of the eye, sus- ng-forms from the ribs, pour the rings in place, and then fill in the on forms supported from the rings and ribs.

SPAN of the dome is 132 ft, the CIRCUMFERENCE at the base is 414.7 e of the suspension of the panel-forms, it is well to keep the PANEL-

rl and T. F. Chase, Engineering Record, Oct. 24, 1914.

l practice has been to keep the resistance-line within the MIDDLE THIRD in lly. In reinforced-concrete arches and domes it may depart a small dis- the middle third, but there should be sufficient steel to resist any tension The ribs of domes differ from ordinary arches as they are rigidly braced ιnd the slab-panels.

: of this example is similar to the dome over the Hippodrome at Copen- rk, by Christiani and Nielsen. See the periodical, Concrete, for December,

ution of this example all calculations have been made with the slide-rule.

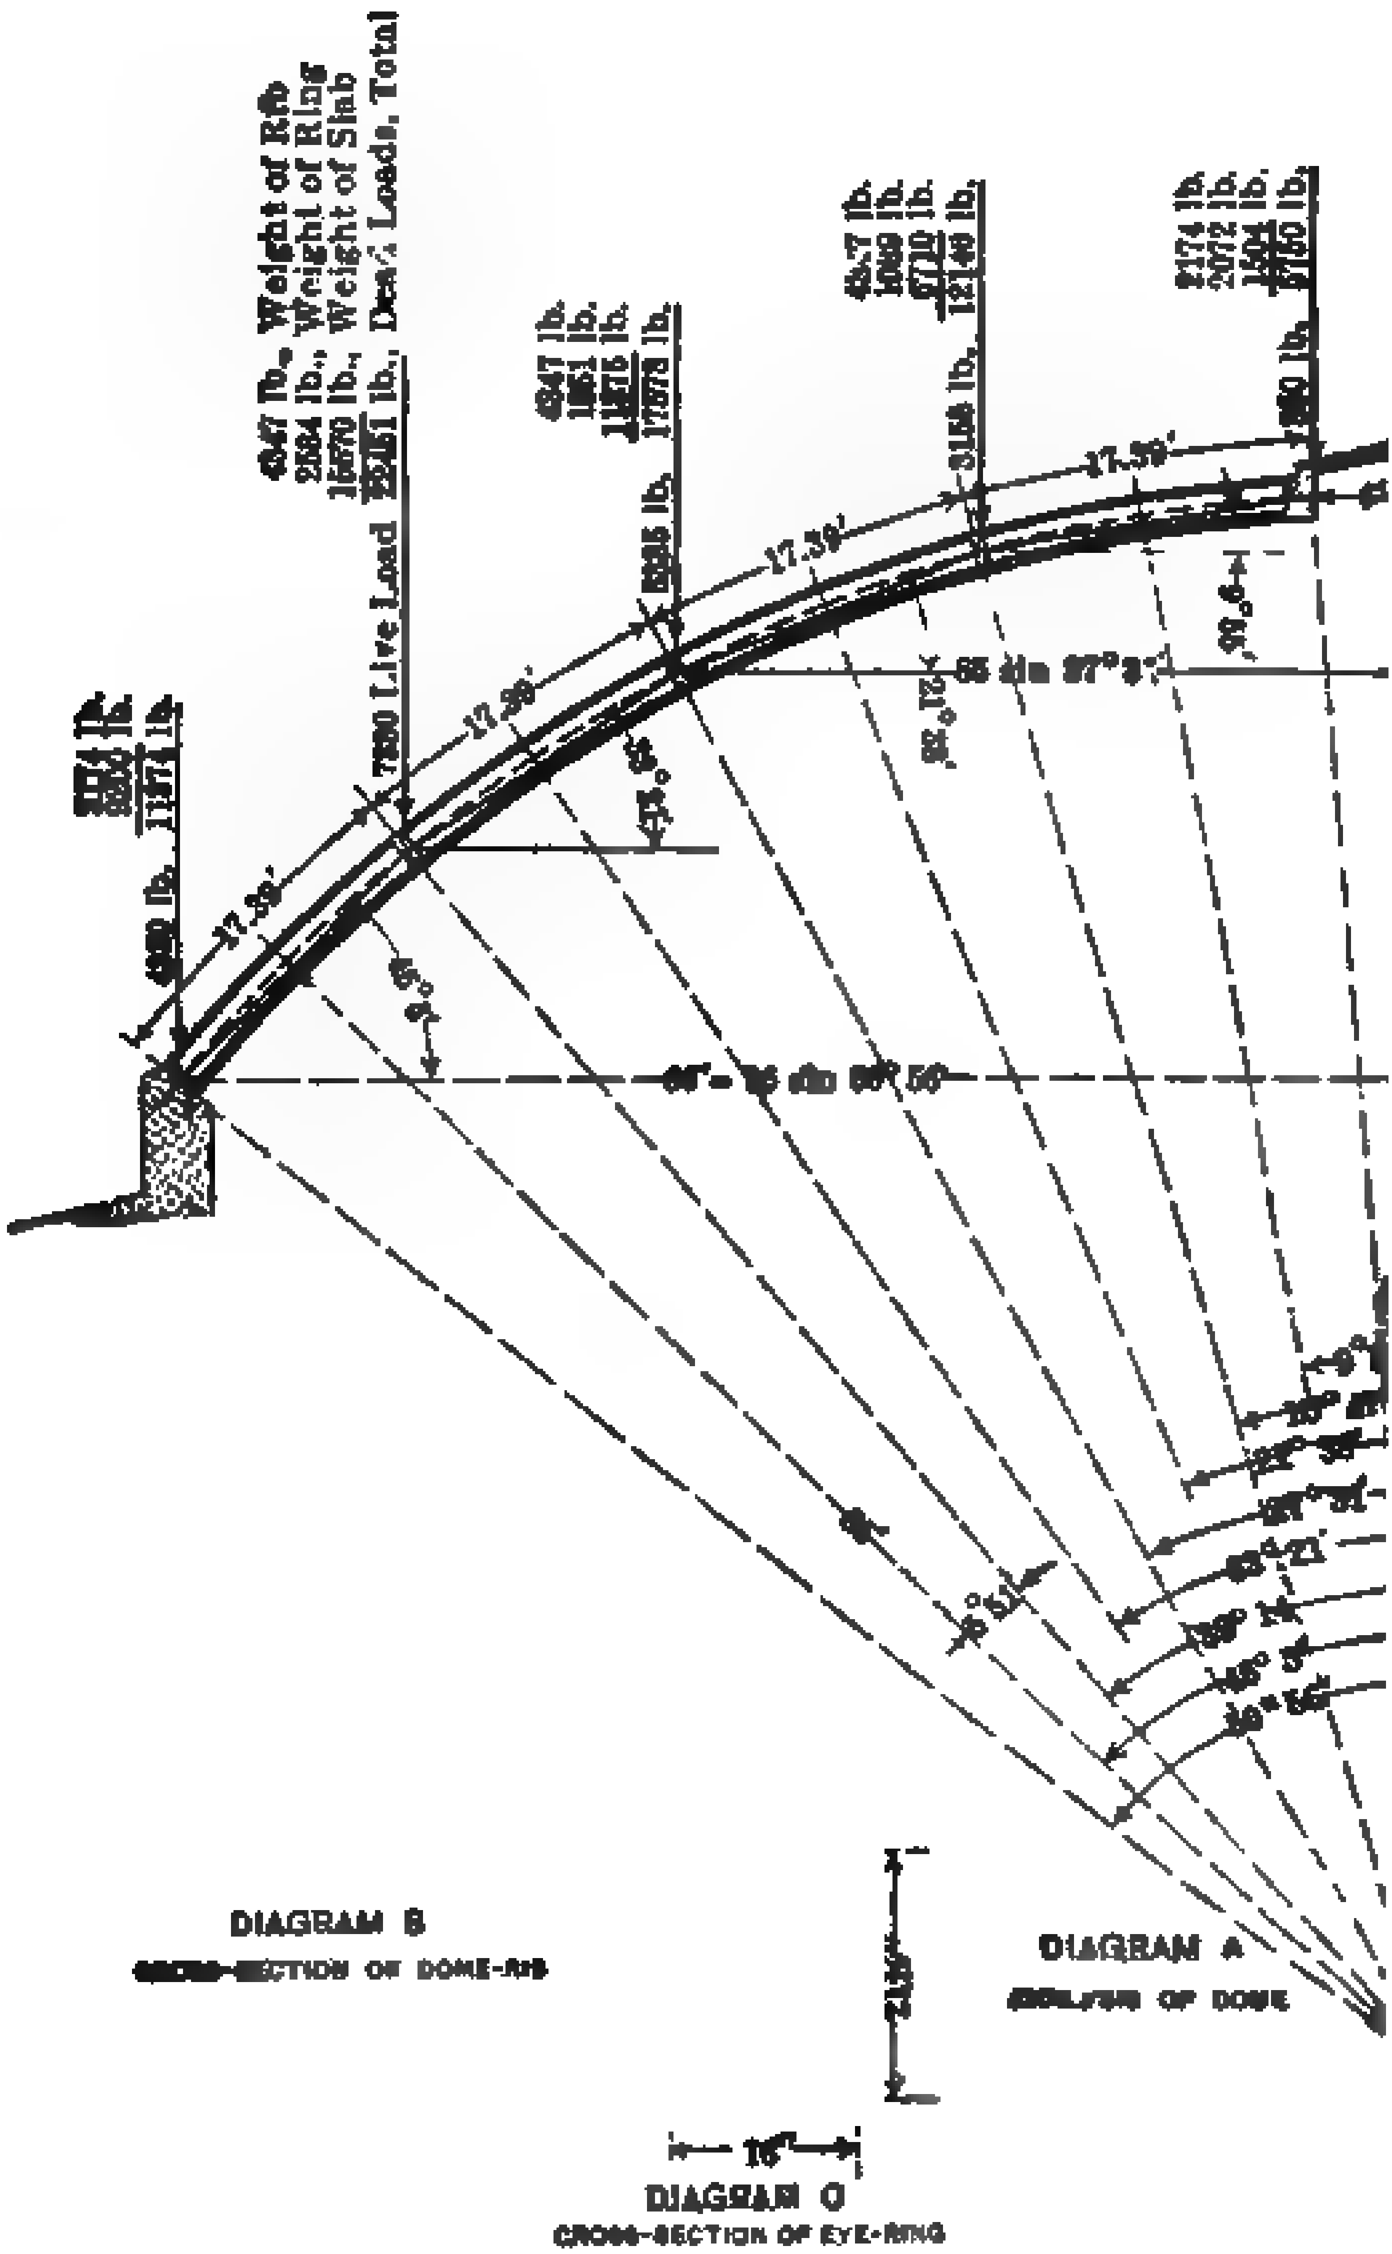

Fig. 5. Segmental Concrete Ribbed Dome

within about a 20-ft limit. Hence twenty ribs are necessary. With TERMEDIATE RINGS, the lower panels are approximately square. The : not to show below the ceiling, and hence a narrower spacing toward is unnecessary for appearance. For preliminary calculations, allowing per lin ft for the eye-ring and the load due to a glass covering over 250 lb per ft for the weight of the ribs, and 150 lb per ft for the weight termediate rings; and assuming a slab-thickness of 3½ in, a suspended eiling ¾ in thick, and 25 lb per sq ft of surface for snow-loads and wind- an equivalent of a 2-in thickness of concrete), the loading on the ribs is ι in Diagram *A* of Fig. 5. To illustrate the METHOD OF DETERMINING DS, the calculations for the loading at the lower intermediate ring are The WEIGHT OF THE RIB is $250 \times 17.39 = 4\,347$ lb. The WEIGHT OF G is $150 \dfrac{2 \times \pi \times 85 \times \sin 39° 14'}{20} = 2\,534$ lb. The WEIGHT OF THE D CEILING between $\theta = 33° 21'$ and $\theta = 45° 5'$ is, from the curves in with $\dfrac{cr}{a} = 0$,

$$\frac{\cdot\left(\frac{3\frac{1}{2}+\frac{3}{4}}{12}\right)(85)^2(1.84) - 150\left(\frac{3\frac{1}{2}+\frac{3}{4}}{12}\right)(85)^2(1.03)}{20} = 15\,570 \text{ lb}$$

l dead load is

$$4\,347 + 2\,534 + 15\,570 = 22\,451 \text{ lb}$$

:al live load is

$$\frac{15\,570 \times 2}{3\frac{1}{2} + \frac{3}{4}} = 7\,330 \text{ lb}$$

ess D_4 (see method in Fig. 4A), in the lower section of the rib is the nd according to Schwedler's formulas, page 1223, is

$$\frac{6\,600 + 15\,301 + 22\,908 + 29\,781}{\sin 45° 5'} = 105\,400 \text{ lb}$$

NTRICITY of the stress D_4 is

$$85 - (85 \cos 5° 51') = 0.445 \text{ ft}$$

ent due to the ECCENTRICITY of D_4 is

$$105\,400 \text{ lb} \times 0.445 \text{ ft} = 46\,903 \text{ ft-lb, or } 562\,836 \text{ in-lb}$$

st the COLUMN-LIKE COMPRESSION of D_4 there is required a cross-sec- ι of rib of

$$\frac{105\,400}{500} = 211 \text{ sq in of concrete}$$

st the effect of the ECCENTRICITY of the stress D_4, it is necessary to ugh steel so that the total stress in it, multiplied by the distance ie top and bottom steel reinforcements, is equal to the moment, 562 836 idy found.

ie ECCENTRICITY of D_4 is 0.445 ft, and the line of action of the thrust pt within the MIDDLE HALF OF THE RIB,* the rib will be

$$4 \times 0.445 = 1.78 \text{ ft} = 21\tfrac{1}{2} \text{ in in depth}$$

* See foot-note on page 1225.

Allowing 1½ in of concrete for steel-protection at the top and bottom of t rib, the distance between the inner and outer reinforcements is

$$21\tfrac{1}{2} - 3 = 18\tfrac{1}{2} \text{ in}$$

Therefore a stress of

$$\frac{562\,836}{18\tfrac{1}{2}} = 30\,424 \text{ lb}$$

is to be resisted by the steel at the top and bottom. Since there is steel in bo COMPRESSION and TENSION, the allowable UNIT STRESS in it is

$$\left(\frac{650 \times 18\tfrac{1}{2}}{21\tfrac{1}{2}}\right)(15 - 1) = 7\,830 \text{ lb per sq in}$$

This is because the allowable compressive unit stress in the outer fibers of co crete beams is 650 lb per sq in; the ratio of the MODULUS OF ELASTICITY of t steel and of concrete, 15; and the distance between the inner and outer st reinforcements, and the distance of the rib-depth, 18½ and 21½ in respectivel The 1 in the expression (15 − 1) is to take care of the stress carried by t concrete replaced by the steel.

The TOTAL CROSS-SECTION of steel necessary at both the top and bottom of t rib is, therefore,

$$\frac{30\,424}{7\,830} = 3.89 \text{ sq in}$$

furnished by four 1⅛-in round rods. The best arrangement of the 211 sq of concrete, and the steel, results in a cross-sectional shape shown in Diagram of Fig. 5. The STIRRUPS should be spaced not more than three fourths of th distance between lines of longitudinal steel, or ¾ × 18½ = 12 in (approximatel and they should be made from ⅜-in round rods. Because of the TIES in th flanges, it is advisable to use small ¼-in rods as STIFFENERS at the inte sections of the ties and stirrups. Projecting LOOPS should be left for fastenin the panel-slabs. The actual weight per linear foot of the ribs is

$$\frac{211}{144} \times 150 = 220 \text{ lb}$$

for the concrete, plus

$$(4 + 3.38) + 11 = 25 \text{ lb}$$

for the steel, equal to a total of 245 lb, as against 250 lb per lin ft previousl allowed in the calculations.

As the ribs are to be precast and raised into place, it is necessary to determin whether they are of sufficient strength for this, and whether they will stand, u supported by the rings, without breaking under their own weight. By conside ing the ribs to be simple arches, and testing them by determining the line thrust, it is found that they are amply safe. In order to resist the thrusts stresses developed by raising the ribs into place, it is necessary to tie the en together with bow-string rods.

The stresses in all of the rings, except the FOOTING-RING, are compressiv This is because they are all above the CRITICAL ANGLE. (See Smooth-She Domes.) Therefore, in determining the stresses by Schwedler's formulas, onl the equations for the MINIMUM VALUES of T_1, T_2, T_3, and T_4 need be used.

The stress in the EYE-RING is

$$-\frac{(5\,750 + 850)\cot 9^\circ\,55'}{2\sin\frac{\pi}{20}} = -120\,600 \text{ lb}$$

ress in the FIRST INTERMEDIATE RING is

$$\frac{750 \cot 9° 55') - (5\,750 + 12\,146 + 3\,155) \cot 21° 38'}{2 \sin \frac{\pi}{20}} = -65\,000 \text{ lb}$$

ess in the SECOND INTERMEDIATE RING is

$$\frac{+ 12\,146) \cot 21° 38' - (5\,750 + 12\,146 + 17\,573 + 5\,335) \cot 33° 21'}{2 \sin \frac{\pi}{20}}$$

$$= -53\,900 \text{ lb}$$

ess in the THIRD INTERMEDIATE RING IS

$$\frac{12\,146+17\,573) \cot 33° 21' - (5\,750+12\,146+17\,573+22\,451+7\,330) \cot 45° 5'}{2 \sin \frac{\pi}{20}}$$

$$= -35\,600 \text{ lb}$$

ess in the FOOTING-RING is tensile, and hence the equation for the MAX-
LUE of T_5 gives

$$\frac{+ 850 + 12\,146 + 3\,155 + 17\,573 + 5\,335 + 22\,451 + 7\,330) \cot 45° 5'}{2 \sin \frac{\pi}{20}} = 238\,000 \text{ lb}$$

-RING should have $\frac{120\,600}{500} = 242$ sq in of concrete, but for appearance it e as wide as or wider than the ribs; hence it is made $21\frac{1}{8}$ in high and 16 This size allows, also, a firm ANCHORAGE for the rib-reinforcing. With einforcing it requires four $1\frac{1}{8}$-in round rods. (See Diagram C, Fig. 5.) intermediate ring should be

$$\frac{65\,000}{500} = 130 \text{ sq in}$$

ection, requiring a 7-in width and a $18\frac{1}{2}$-in height, to resist the load, as a As the ring must also act as a BEAM, carrying its own weight, the f half the slab, and the live load (the forms taking the place of the live ng construction), steel must be added to resist the BENDING MOMENT

$$\frac{\left(\frac{130}{144} \times 150\right) \left(\frac{2\pi 85 \sin 15° 47'}{20}\right)^2 + \left(\frac{6\,710 + 3\,155}{2}\right) \left(\frac{2\pi 85 \sin 15° 47'}{20}\right)}{12}$$

70 ft-lb = 42 840 in-lb

steel, in TENSION and COMPRESSION, must be added to keep the addi- ess in the concrete, due to this moment, down to 150 lb per sq in, since = 650 lb per sq in is the MAXIMUM ALLOWABLE COMPRESSIVE STRESS ncrete of the beam. From Formula (1) page 925, or Formula (5) page

$$K = \frac{42\,840}{7 \times (17)^2} = 21.2$$

mulas (2), (3) and (4), (pages 925–6), when $K = 21.2$ and $S_t = 16\,000$ in; $S_c = 245$ lb per sq in, $p = 0.0014$, and $x = 0.185$. Since S_c must

not exceed 150 lb per sq in, it is necessary to add COMPRESSION-STEEL to resist stress of

$$\left(\frac{245-150}{2}\right)(7)(0.185\times 17) = 1\,040 \text{ lb}$$

The allowable stress in the COMPRESSION-STEEL (page 1228), less the stress already allowed for the concrete which is replaced by the steel, if placed 1½ in from the outside, is

$$\left(\frac{650}{0.185\times 17}\right)\left((0.185\times 17)-1.5\right)(15-1) = 4\,770 \text{ lb per sq in}$$

The amount of COMPRESSION-STEEL is, therefore,

$$\frac{1\,040}{4\,770} = 0.22 \text{ sq in, cross-section}$$

The tensile-steel necessary is

$$0.0014\times 7\times 17 = 0.16 \text{ sq in}$$

but because of the NEGATIVE MOMENT at the ribs, the same cross-sectional area is used as for COMPRESSION, that is, 0.22 sq in, furnished by two ⅜-in round rods. The UNIT-SHEAR is

$$\frac{\left(\frac{130}{144}\times 150\right)\left(\frac{2\pi 85 \sin 15^\circ 47'}{20}\right)+\left(\frac{6\,710+3\,155}{2}\right)}{7\times 17\times\left(1-\frac{0.185}{3}\right)\times 2} = 18.6 \text{ lb per sq in}$$

No STIRRUPS are necessary to resist shear, but stirrups made from ¼-in round rods should be spaced about 18 in on centers, to tie the panel-slabs securely to the ring.

The SECOND INTERMEDIATE RING, if made the same size as the first, will have a stress of

$$\frac{53\,900}{7\times 18\tfrac{1}{2}} = 416 \text{ lb per sq in}$$

The MOMENT will be

$$\frac{\left(\frac{130}{144}\times 150\right)\left(\frac{2\pi 85 \sin 27^\circ 31'}{20}\right)^2+\left(\frac{11\,375+5\,335}{2}\right)\left(\frac{2\pi 85 \sin 27^\circ 31'}{20}\right)}{12}$$

$$= 10\,300 \text{ ft-lb} = 123\,600 \text{ in-lb}$$

From Formulas (1), (2), (3), and (4), (pages 925–6), $K = 61.2$, $S_c = 455$ lb per sq in, $p = 0.0043$, and $x = 0.3$. Since S_c cannot exceed $650 - 416 = 234$ lb per sq in, the COMPRESSION-STEEL must resist

$$\left(\frac{455-284}{2}\right)(7)(0.3\times 17) = 3\,930 \text{ lb}$$

The section-area of the COMPRESSION-STEEL is, therefore,

$$\frac{3\,930}{\left(\frac{650}{0.3\times 17}\right)\left((0.3\times 17)-1.5\right)(15-1)} = 0.62 \text{ sq in}$$

furnished by two ¾-in round rods at top and bottom. The UNIT SHEAR is

$$\frac{\times 150)\left(\frac{2785 \sin 27^\circ 31'}{20}\right)^2 + \left(\frac{11\,375 + 5\,335}{2}\right)}{7 \times 17 \times \left(1 - \frac{0.3}{3}\right) \times 2} = 46.9 \text{ in per sq in}$$

efore necessary to resist 46.9 − 40 = 6.9 lb per sq in of shear, with that is, with two ¼-in round-rod stirrups, spaced 12 in apart at the the others 18 in apart through the remaining distances.

IRD INTERMEDIATE RING is 7 by 18½ in in section, with two ⅞-in s at top and bottom, and with two ⅜-in round-rod STIRRUPS, spaced at the ends, two more, spaced 12 in, and the rest spaced 18 in.

MENT due to the ECCENTRICITY of the COLUMN-LIKE THRUST, that is, udinal horizontal compressive stress, in the rings is resisted by the slabs. act analysis may be made by considering only the NORMAL COMPONENTS ADS on the rings in determining these moments.

TING-RING must have enough tensile-steel to resist the outward PUSH of the ribs, that is $\frac{238\,000}{16\,000} = 14.9$ sq in of steel cross-section. In this, if the ring acts as a BEAM, there must be sufficient steel to resist it due to the combined weights of the dome and the ring itself.

EL-SLABS being domical and above the critical angle, are in com- nd should be designed as illustrated in the discussion of Smooth- es.

2. Vaults *

ation. Vaults may be conveniently considered under the following (1) Barrel vaults, (2) Groined vaults, and (3) Ribbed vaults (Masonry, amed).

Considerations. A knowledge of the ELASTIC THEORY OF ARCHES bility of buttresses is necessary in a rigid investigation of vaults, since involves the application of the principles of that theory. (See, also, II and VIII.) In any vault, lines of action of the stresses or thrusts through the material between certain limiting lines; otherwise the ail. These thrusts are brought to the grade-line, or to foundations, ften buttressed in the case of barrel vaults, and by piers and but- he case of groined and ribbed vaults. By building vaults of light uch as hollow bricks or hollow tiles, the magnitude of the thrusts are nd lighter walls, piers, or buttresses can be used.

Fig. 1. Three Methods of Building Barrel Vaults

aults. Fig. 1, (*a*), (*b*), and (*c*), illustrates three methods of building LTS. In (*c*) the longitudinal ribs are merely for appearance, as

* atment of this subject may be found in the Handbuch der Architektur, 's Baukonstructions Lehre.

they do not strengthen the vault. The diagrams (*a*) and (*b*), Fig. 2, illustrat methods of disengaging the masonry of barrel vaults from the walls. Dia (*b*) is the better me and improves the ap ance of the vault o inside. Diagrams (*c*) (*d*) illustrate the u stone skewbacks for mental vaults.

(*a*) (*c*) (*d*) (*b*)

Fig. 2. Methods of Joining Barrel Vaults to Walls

Strength of B Vaults. Barrel vaults be considered as a se OF ARCHES set next to other; and hence if a tion one unit long is fo safe when investigated an arch, the vault itse considered safe. By be ing the wall and the v together as a unit, point on the arc 60° from the vertical or crown, that is, to a point on the trados one third of the distance from the horizontal spring-line, the actual is materially decreased. With the spring-line at 60°, the line of thrust in unloaded arch or barrel vault of an equal thickness throughout, will remain within a strip whose radial thickness or width is about one forty-second of the radius. If the line of thrust is to remain within the middle third of the arch-ring or vault-ring, t should be $(r/42) \times 3 = r/14$. If it is to remain within the middle half, t should be $(r/42) \times 2 = r/21$. In the following example, the theory of the middle half will be followed, in which $t = r/21$. If it were assumed that $t = r/14$, the line of thrust being kept within the middle third, the span of the vault in the example would have to be changed from 21 to 14 ft.

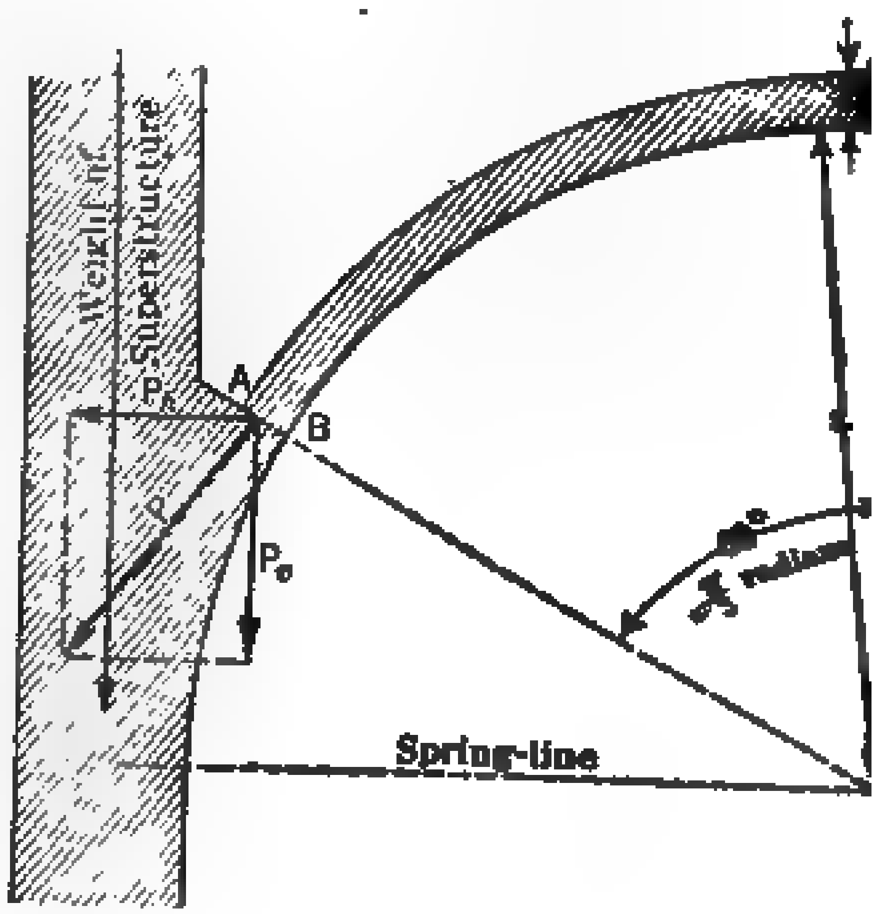

Fig. 3. Analysis of Barrel Vault

If built, then, as described (Fig. 3), the minimum thickness of the unloa vault-shell is about one twenty-first of the vault-radius, that is,

$$t = r/21$$

The VERTICAL COMPONENT P_v of the thrust P is equal to the weight of half free vault, that is, of the section $ABCD$. It can be shown that the HORIZON

ENT P_h of the thrust is 0.79 of the vertical component, and that the s not at right-angles with the spring-line AB; that is,

$$P_h = 0.79P$$

ple. It is required to construct a BARREL VAULT over a corridor 21 ft The vault-radius is 10½ ft, and the minimum thickness of the shell is $= 0.5$ ft $= 6$ in. If built of bricks it is cheaper to build a ribbed vault, as -dimensions of bricks are approximately 4 in, 8 in, 12 in, etc. Referring ., it is found that a 4-in vault with ribs 4 by 8 in every 3 ft 3 in, is equiva-

6. Barrel Vaults, Ribbed and Non-ribbed. Equivalent Thicknesses

6-in vault, and hence would be used. The brick masonry weighs cu ft.

RTICAL COMPONENT P_v of the thrust is

$$\frac{[\tfrac{1}{4} \times 1/3\pi \times 10.5 \times 125] + [4/12 \times 8/12 \times 1/3\pi(10.5 + 0.33) \times 125]}{3\tfrac{1}{4}}$$

$$= 557 \text{ lb per lin ft}$$

ZONTAL COMPONENT P_h of the thrust is $0.79 \times 557 = 440$ lb per lin ft. rting wall must be thick enough, buttressed enough, or loaded suf-rom above, to take care of this horizontal component of the thrust. s a graphical analysis of the stresses in this vault It will be noticed hat the line of pressure remains in the MIDDLE HALF of the vault-thick-effler, after numerous tests of vaults, stated * that if one fourth the

* Theorie der Gewölbe.

vault-thickness is deducted at the extrados, and one fourth at the intrados, an that if the line of pressure found according to the elastic theory of arches

Fig. 5. Graphical Determination of Stresses in a Barrel Vault

confined to the remaining portion, that is, the MIDDLE HALF, then the vault m be considered safe. Fig. 6 shows the resistance-line passing slightly outside t

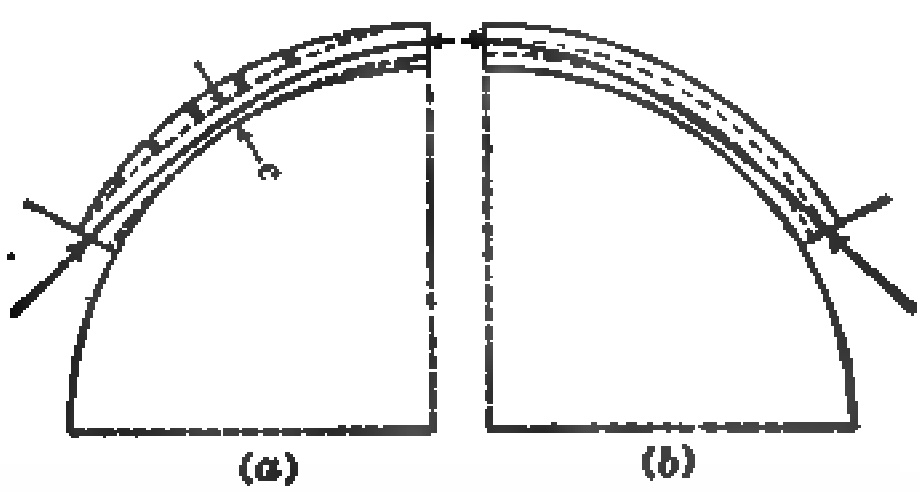

Fig. 6. Line of Pressure through Vault-thickness

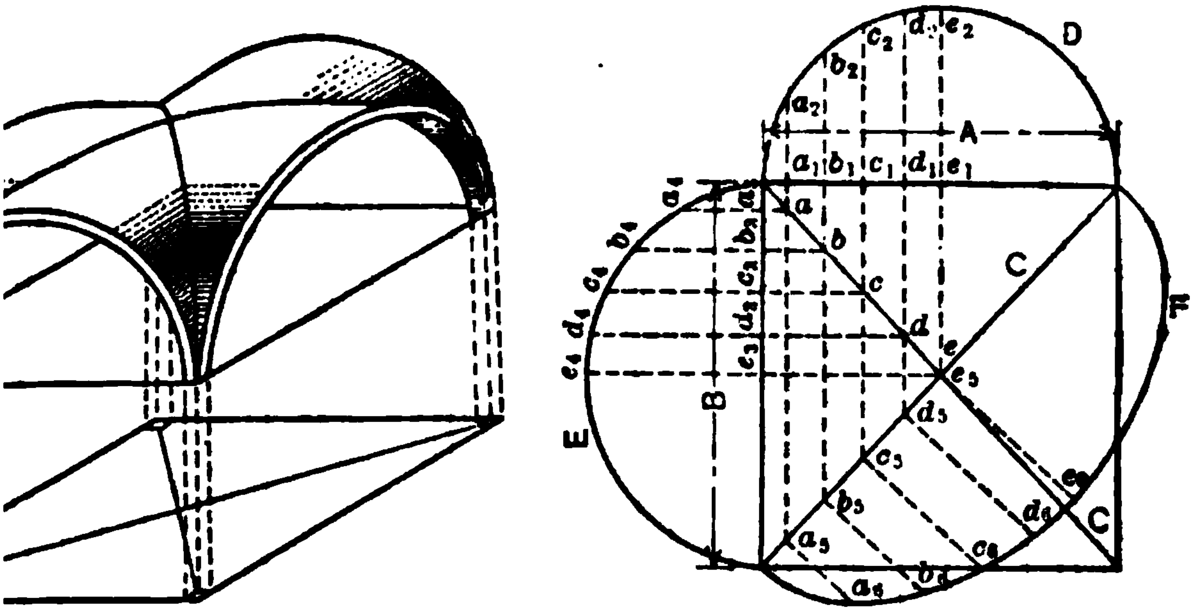
middle third.* It illustrates the less conservative theory that the resistan line might in some cases pass near the outside of the middle half. The arch vault in Diagram (b) of Fig. 6 would have a greater tendency to fail accordi to the middle-third theory, because the line of pressure or resistance-li passes outside of the middle third. Diagram (a) of Fig. 6 shows the same a or vault with the shell cut so that the line of pressure passes down the exact cen of the uncut portion. This results in a sort of theoretical or ideal arch-for

* See foot-note relating to Concrete Ribbed Domes, page 1225.

se the thickness of part c must be sufficient to develop a safe compres-
istance in the material, and it is advisable to add sufficient steel to take
ny tension in the parts farthest from the resistance-line. Vaulted con-
n is often relatively protected and free from the live loads and moving
o which arches are generally subjected; and for such construction
·'s conclusions are considered valid.

ied Vaults. A GROINED VAULT is formed by the intersection of two
VAULTS. (See (a), Fig. 7.) By using groined vaults it is possible to



(a) ective, Showing Penetrations and Intersections

(b) Intersecting Vaults of Different Widths

Fig. 7. Groined Vault

tops of windows and doors above the spring-lines of the vaults, and to
te the pressures or thrusts on piers or columns.

. The intersections of two vaults, called GROINS, are straight lines in
projection, only when they are of the same curvature and height.
lts are of different widths, it is best to make one semicircular, draw
ntal projections of the groins as straight lines, and then determine the
the other vault. This is illustrated in Fig. 7 (b). Vault A is semi-
d has a span A. Vault B has a span B. CC are the GROINS, and D is
r contour of the narrow vault. Any points, a, b, c, etc., are chosen at
d lines a–a_1, b–b_1, c–c_1, etc., and a–a_4, b–b_4, c–c_4, etc., drawn parallel to
the respective vaults. The line a_3–a_4 is laid off equal to a_1–a_2; b_3–b_4,
b_2, etc. The smooth curve connecting a_4, b_4, c_4, etc., is the contour E
t B. In like manner the contour F of the groins is found by similarly
$_5$–a_6, b_5–b_6, etc., equal to a_1–a_2, b_1–b_2, etc.

LT-SHELLS, at the intersections or groins, should never have what
lled MITER-JOINTS. The vaults should be monolithic or there should
d ribs to carry the vault-shells and transmit the thrusts to the piers.
secting vaults are of stone, and of the same diameter, the groins may
shown in Fig. 8 (a) for small vaults, or as in Fig. 8 (b) for larger
Fig. 8 (a) the GROIN-STONES are L-shaped and are cut so as to carry
ourses of one vault around to the other vault. The stone shown in
) of Fig. 8 is shown in plan at b, with two views at c and d. A better
hown in Fig. 8 (b). Here the groin-stones are cut so that the joints

are normal to the groins, thus forming concealed ribs. This bearing-surfa is obtained as follows. Point *a*, the intersection of an extended vault-joint a the groin-edge, is projected down to *a′* and *b′*, the intersections of the projecti line and the assumed side and center lines of the rib. Point *b′* is projected up

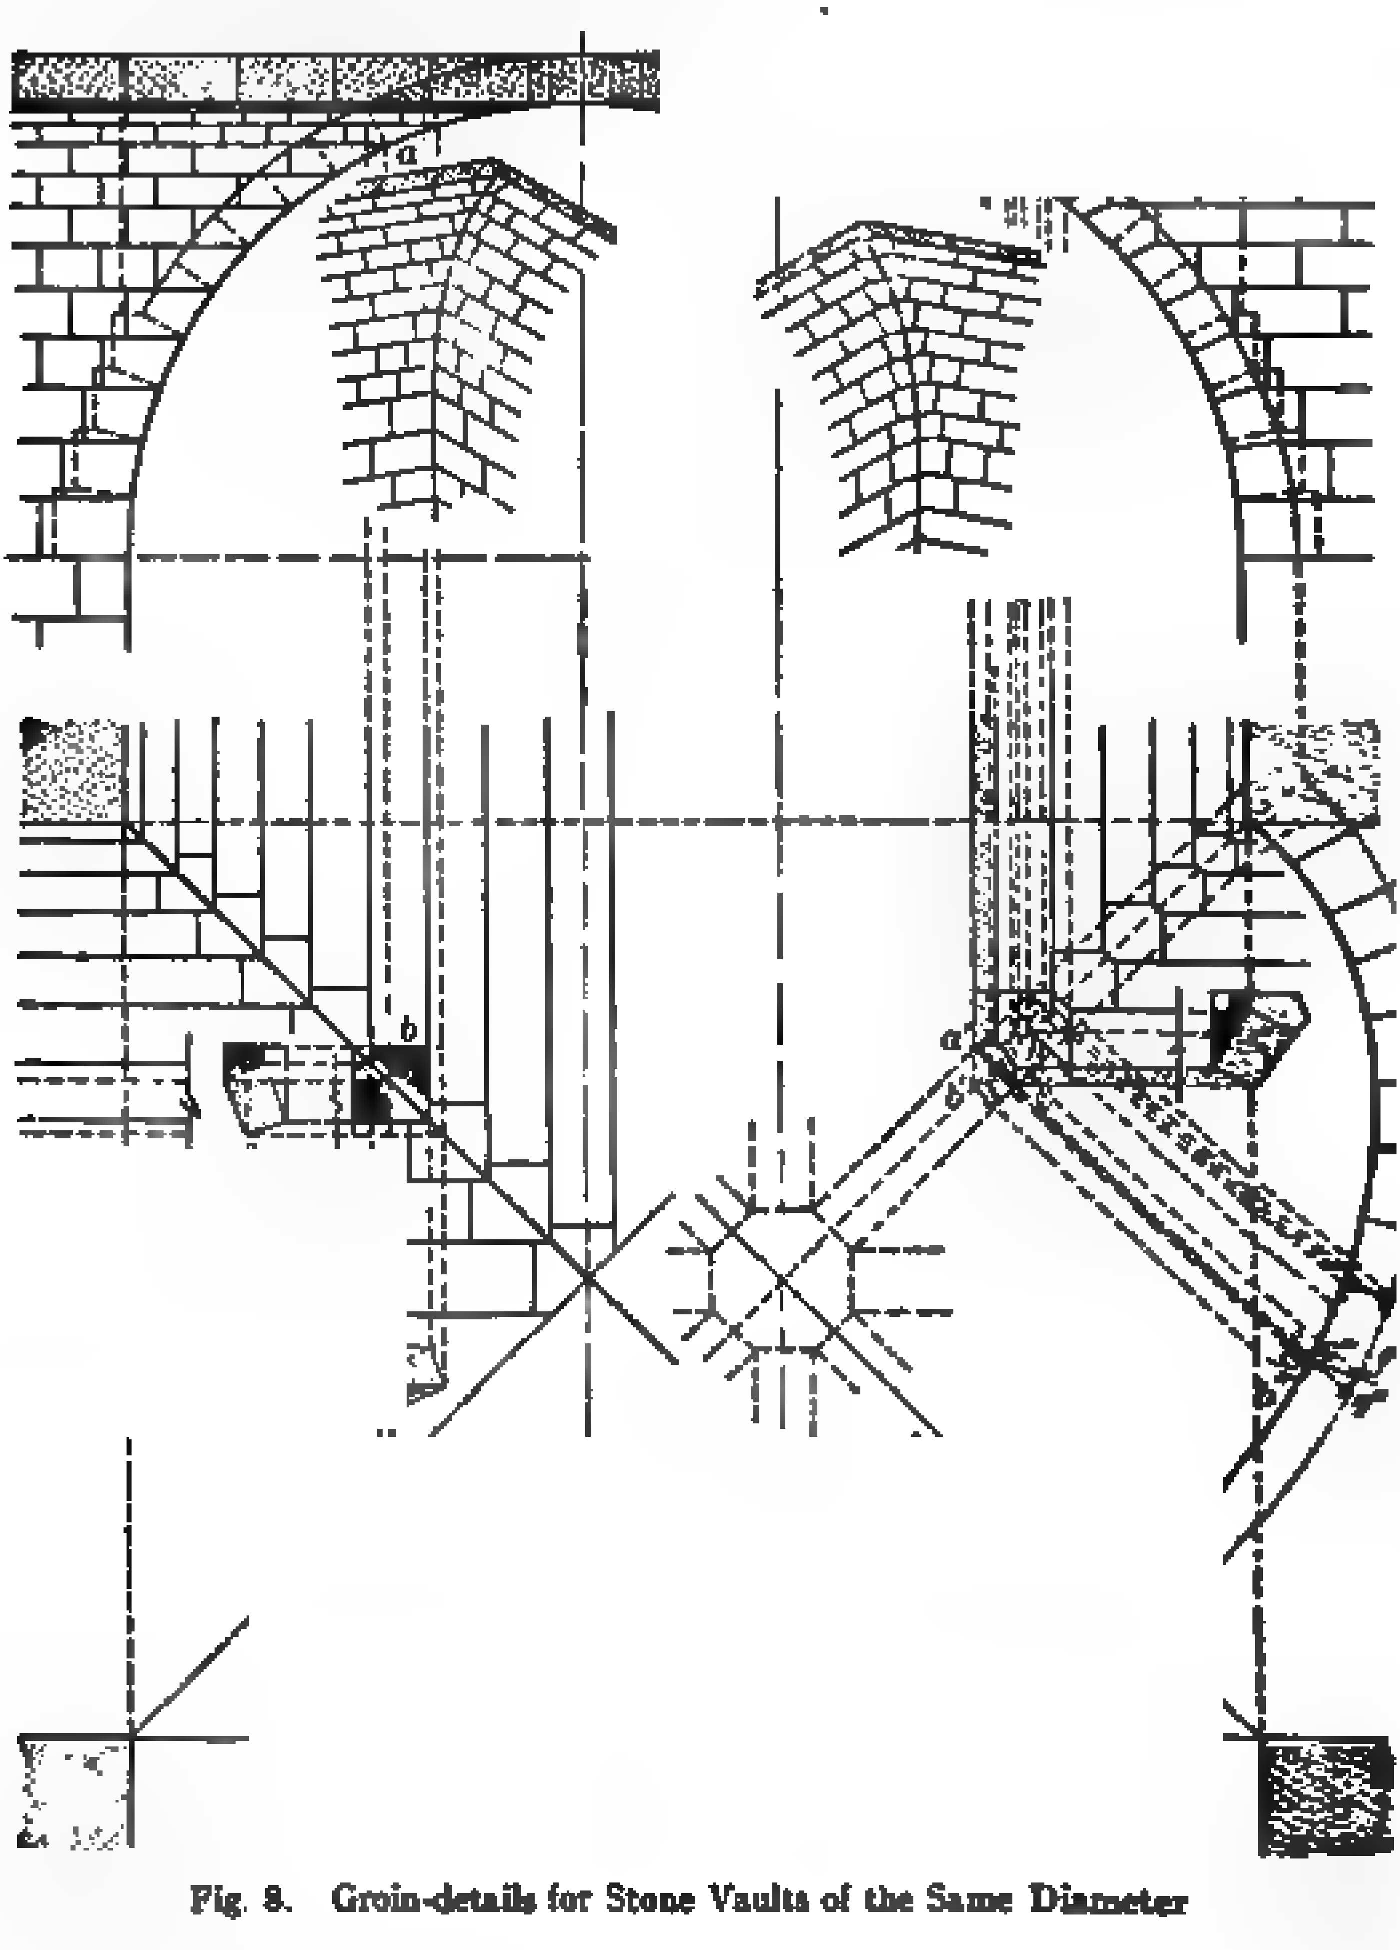


Fig. 8. Groin-details for Stone Vaults of the Same Diameter

b″, a point on the center line or edge of the rib. From *b″* a horizontal line int sects with a line projected up from *a′* to give *c″* a point on the joint, which drawn normal to the groin. The intersection *d″* of this joint with the gro edge is projected down to *d′* on the center line of the rib. By connect

ʹ, and d'' and e' (the point opposite a' on the other side of the rib)
line, the lower edge of the bearing-surface is determined.
d'' and e' projected up determine d and e, the same points in elev

g. 9. Groin-details for Stone Vaults of Different Diameters

s on these curved lines can be found by choosing points betw
rojecting them in the same way as in the method used to fi
of f. The procedure is as follows. The point f is projected

to the center line of the rib, locating g'. Then g' is projected up to g'', the i section with the line representing the joining of the upper surfaces of the va A horizontal line is projected over from g'' to f''', the point of intersection with normal joint. The point f''' is projected down to f', on the projecting line fro By connecting f' and h' (h' is opposite f' and equidistant from the center lin the rib) with a straight line, the upper edge of the bearing-surface is determi The point h is found by projecting up from h'. By connecting a' and f', a and h'; also a and f, and e and h, the side edges of the bearing-joint are loc The lower bearing-surface of a stone, or the upper bearing-surface of the lower stone, is found in a similar manner.

If the vaults are not of the same diameter, either of two methods may be u The number of stone courses in both vaults may be made the same, thus mak the courses in the wide vault wider than those in the narrow vault, and method of finding the shape of the groin-stones is similar to that shown in Fig. 8 or the stones may be the same width, thus making a greater number of cours the wide vault than in the narrow vault. In the latter case the groin-stones are termined as in Fig. 9. To take care of the different number of courses in the vaults, one course in the narrow vault is sometimes made to receive two co in the wide vault, as shown by stone A in Fig. 9. Because the joint a is hi than the joint b, there results a peak toward the side of the groin-line. Th cut off at right-angles to the groin, thus making the bearing-surface c. surface is determined as follows. The intersection of the joint-planes d a is at f. The vertical projection f_1, of f, is drawn through h_1, found by proje up h and g, and a horizontal line from g_1. The intersection of f_1 and a through g_1, normal to the groin-curve gives i_1, which, projected to i, gives intersection of the sides of the bearing-surfac

The point j is found by projecting up k, intersection of a and the diagonal, to k_1; projecting k_1 to j_1, the intersection with normal line; and then projecting j_1 to j. connecting g and j with a curved line (o points of which are determined by draw lines parallel to a and proceeding by the met used in finding j); and g and i, and j and i, straight lines; the sides of c are determined.

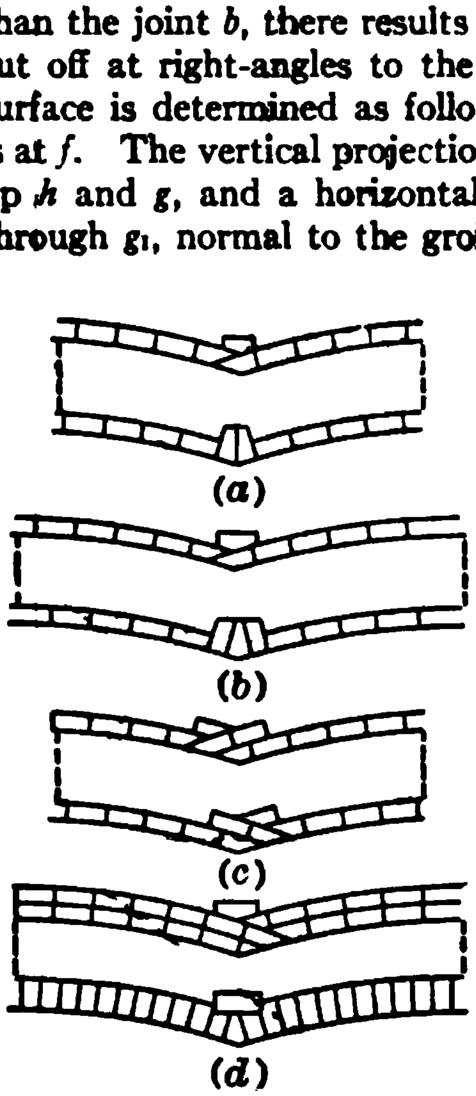

Fig. 10. Groins of Brick Vaults

If the vaults are built of brick, it is bette run the courses at right-angles to the gr thus giving a chance for the bricks to over as shown in Fig. 10. If the brick courses to run parallel to the center line of the vault is necessary to use stone ribs to carry the sh

Determination of the Stresses in Groi Vaults. The problem of a groined vault s ning a RECTANGULAR AREA which is not squ is here considered, as a vault spannin SQUARE AREA offers fewer difficulties and ca worked out on the same principles. The problem is to span an area, wh half-length of the short diameter is a, and whose half-length of the long diam is b, Fig. 11 (a). In order to obtain a more stable construction, the point of int section of the crowns of the vault is raised a distance $cd = c'd$, thus giving crown of the long-span vault a slope ce and the crown of the short-span v a slope $c'f$. The vault is divided into strips A, B, C, etc., and A', B', C', from the rib R, as shown in the projected area in Fig. 11 (a). The rib R

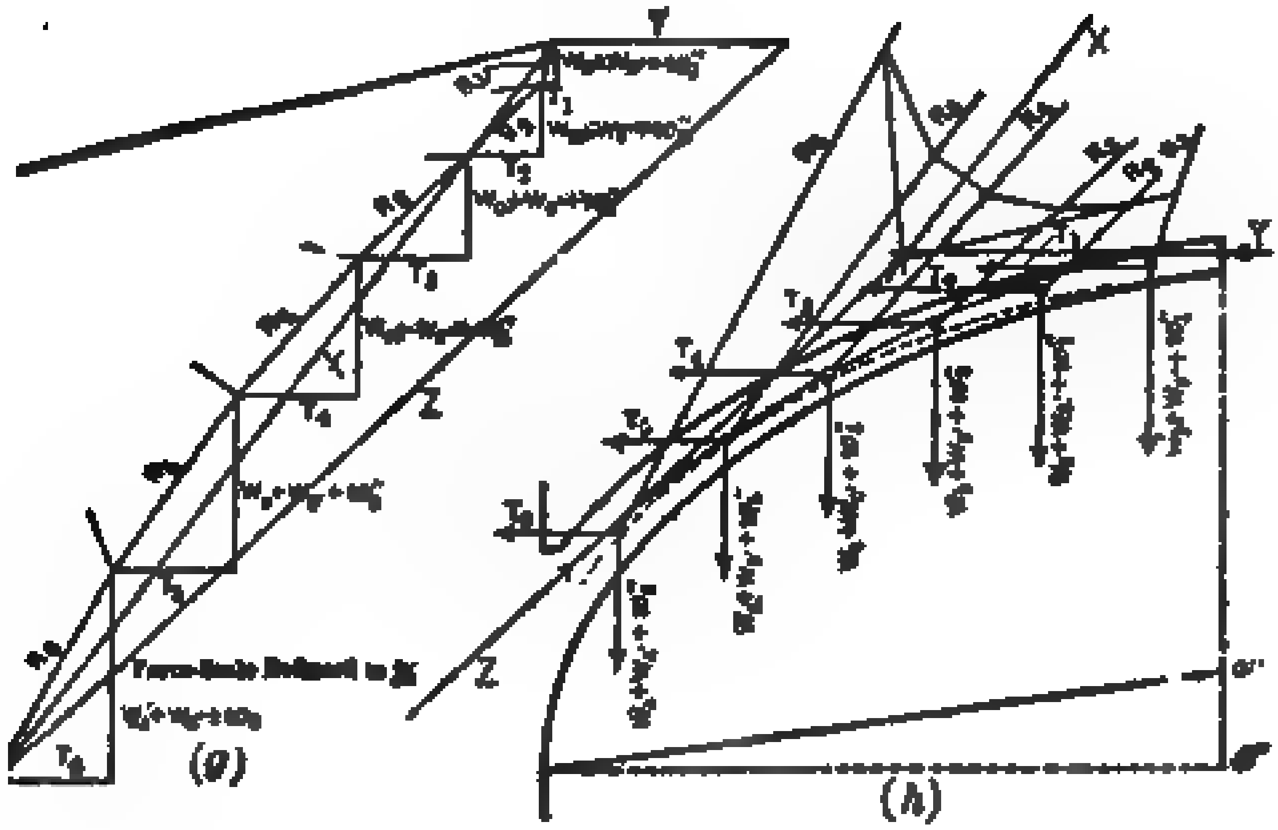

Fig. 11. Determination of Stresses in Groined Vaults

given a width equal to the assumed width of the supporting diagonal concea arch, and the widths A, B, C, etc., and A', B', C', etc., are obtained by dividi the two vaults into the same number of equal parts. These strips are conside as adjacent arches resting on the rib R. For simplification the line of pres or resistance-line of each strip is placed in the center of that strip as gk in and $g'k'$ in A'. The error in this is on the side of safety.

Even though the projected areas of the two intersecting vaults are the sa the actual surface-area of the smaller-span vault is slightly larger than that the longer-span vault. Therefore, if the vaults are of the same thickness, shorter-span vault is slightly heavier than the larger-span vault. In order have the resultants of the horizontal components of the thrusts from strip and strip A', strip B and strip B', etc., parallel to the direction of the rib the procedure is as follows.

The thrusts of the strips on the heavier side, that is of strips A, B, C, D, and F, are determined as shown in Fig. 11 (*b*) and (*c*). The curvature of strips being the same, the work can be considerably lessened by dividing arch into sections of unequal lengths for weight-determinations. The divid line for the sections is found, by projecting up the point of intersection of the of pressure of each strip and the side of the rib R, as g to g', h to h', etc. weights w_1, w_2, w_3, etc., of each section are then determined and the compo load-line drawn as in Fig. 11 (*c*). The positions of W_A, W_B, W_C, etc., Diagram (*b*) are determined by the usual STRESS-POLYGON. H is then drawn as to be at the upper limit, and the different thrusts so as to act near the lo limit of the middle half of the vault-thickness.* Lines drawn in Fig. 11 parallel to these thrusts, determine their values, and the values of the ho zontal components H_A, H_B, H_C, etc. The weights w'_1, w'_2, w'_3, etc., in Diagr (*d*), are found in the same way, the load-line in Diagram (*f*) drawn, and positions of W_A', W_B', W_C', etc., found as before. H' in Fig. 11 (*d*) is dra at the upper limit of the middle half in this demonstration.* H_A', H_B', H etc., however, must have such values that the resultants of H_A, and H_A', and H_B', etc., are parallel to R. The required values of H_A', H_B', H_C', e are found as in Fig. 11 (*e*), by laying off H_A, H_B, H_C, etc., and draw T_1, T_2, T_3, etc., parallel to R. The resulting values of H_A', H_B', H_C', e are then laid off in Fig. 11 (*f*) and the thrusts drawn. When drawing thrusts in Fig. 11 (*d*) through the intersection, of H' and W_A', H' and W etc., parallel to their directions in Fig. 11 (*f*), it is found that they act w slightly above the lower edge of the middle half.

The rib R is then drawn as in Fig. 11 (*h*) and the points of application of loads located. The LOAD-POLYGON is drawn as in Fig. 11 (*g*). The RESULTA R_1, R_2, etc., are drawn in both Diagrams (*h*) and (*g*) of Fig.11, the position of in Diagram (*h*) found by the usual STRESS-POLYGON, and the THRUSTS Z and determined. The point through which Z, Diagram (*h*), passes at the spring the rib, should be so chosen that the LINE OF PRESSURE remains at least wit the middle half of the rib; or the more usual and conservative limits of middle third may be used. In the case of brick vaults the strips A, B, etc., are taken at right-angles to the groin, resulting in vertical loads, only, the assumed rib.

Ribbed Vaults. In RIBBED VAULTS the ribs are designed to be built fi to be free-standing, and of sufficient strength to support the shell when placed over them. To simplify the construction, all the rib-arcs are ordina made with the same radius, thus making all the ribs disengage each other at

* The theory of the middle third is the one usually followed, as it is the most conser-tive and results in a larger factor of safety. See, also, foot-note on page 1225.

ight. This makes the narrower rib-arches pointed, and the diagonal
s semicircular, but they are all constructed of similar stones with cross-
of the same shape. To determine the points A and B (Fig. 12), at which
become independent of each other and of the wall, the proceeding is as
In plan the clustered ribs are shown just above the column-capitals,
diagonal ribs extending into the wall a distance ab. To find the height
w an arc through a with the same curvature as that of the diagonal rib,
at right-angles to the ribs, in plan, a line from b, until it cuts this arc at
eight cb is the height at A. The height at B, equal to fe, is found in the
r. The WEBS, or parts of the vault-shell supported by the ribs, are

are designed as arches, loaded with the thrusts of the web supported.
sts are determined as illustrated in Fig. 13 II. The vaulting
the half-wall, or transverse rib A, and the half-diagonal rib B, is
any number of equal LUNES, or figures bounded by the two inter-
, and radiating from the AXIS OF THE DOME of which that part of the
a SPHERICAL TRIANGLE. This axis is found by projecting, at right-
the ribs A and B, lines starting at the center of curvature of the ribs

and intersecting at the point e, which is the projection of the axis of the do
The RADIUS OF THE DOME is then R_1 in Fig. 13 II, equal to the distance from

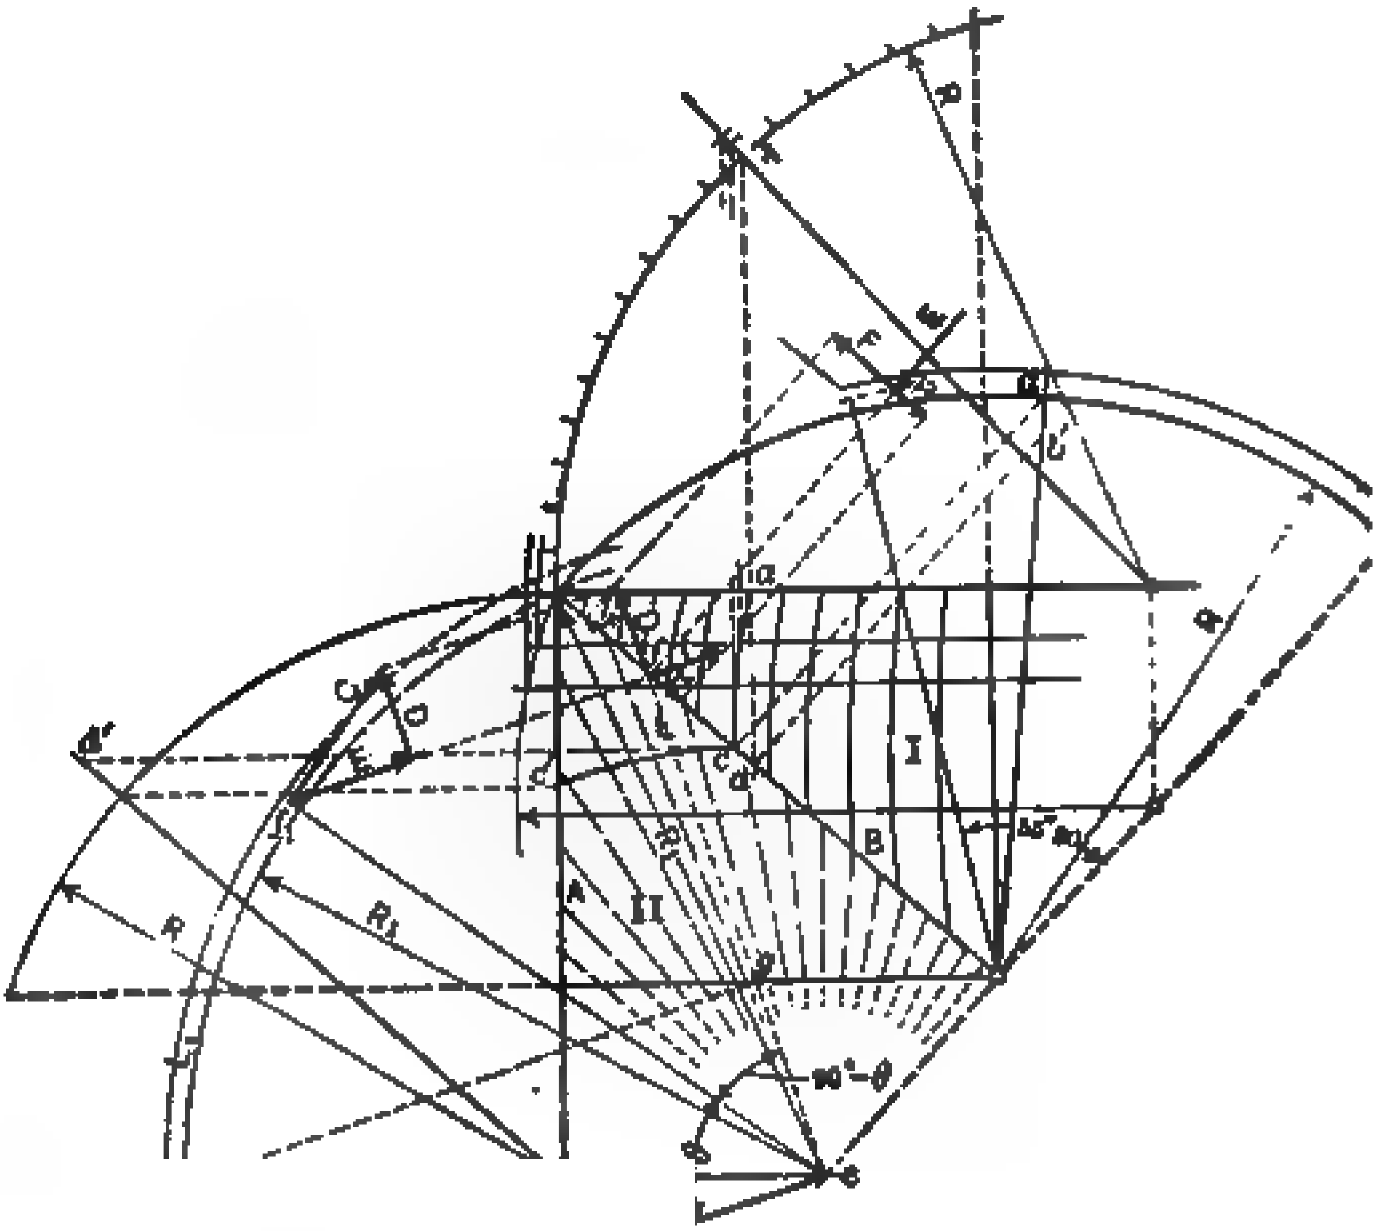

Fig. 13. Determination of Stresses in Vault-ribs

the spring of the diagonal rib B The thrust of each LUNE on the ribs is t
found as shown for lune L

Example. Let the radius R_1, Fig 13 II, be 25 feet, and let the shell be
thick, constructed of stone, and weighing 125 lb per cu ft The angle θ (by me
urement) is 54° 30′, and the angle α is 18° 30′. These are found by project
up from the point of intersection f of the center line of the lune L and the cen
of the rib B, and the intersection g of the center line of the lune L and the cro
line of the vault, to f_1 and g_1, respectively, on the vertical projection L_1 of
lune L.

Using the same notation, equations, and curves as were derived for smoo
SHELL DOMES (page 1214), it is found from Plate II, with $\frac{\sigma}{a} = 0$ and $\alpha = 18°$,
that

$$W_{l-\phi} = -125\,(4/12)\,(25)^2(0.33) = -8\,594 \text{ lb}$$

and that

$$n = \frac{-8\,594}{2\pi(125)(4/12)(25)^2} = -0.0525$$

From Plate I it is found that the CRITICAL ANGLE, for values of $\frac{\sigma}{a} = 0$

.0525, is 55° 30′, and the vaulting should be back-filled as high as this, n.

Plate III, with $\frac{cr}{a} = 0$. and $n = -0.0525$, it is found that at $\theta = 54° 30'$

$$U = (125 \times 4/12 \times 25)(-0.079 + 0.63) = 573 \text{ lb}$$

urement, the width of LUNE L at f is 2 ft; hence the total TANGENTIAL C (Fig. 13), is $2 \times 573 = 1\,146$ lb. The HORIZONTAL COMPONENT D 6 655 lb, and the COMPONENT F (along the rib B) of D is 5 750 lb. The COMPONENT E of C is 9 339 lb.

LUE OF T is found from Plate IV to be $125 \times 4/12 \times (25)^2 \times (-0.004$ $= 7\,570$ lb, and the COMPONENT H (along the rib B) of T is 3 630 lb. RUSTS acting on the rib B of the other LUNES above L are found in the ', and the portion of rib above the back fill investigated as an arch. that portion of the rib below the web is not indicated.

lts with semicircular diagonals of about 33-ft span, the ribs should be 10 in wide and from 10 to 14 in in total height, and the minimum s of the projecting portions of the ribs below the webs, for smaller ould be 3½ in width and 6 in in height.*

ults. TILE VAULTS, as built by the R. Guastavino Company, are d of tiles, from 6 by 12 to 24 in in plan, and 1 in in thickness, and veral layers so as to make a solid, thin shell that is both light and Because of the overlapping of the tiles, the shell has considerable ESISTANCE, and the vaults are practically MONOLITHIC. It is due to the lightness of the construction that the thrusts and the weight of tructure are materially reduced. Ordinarily a finished ACOUSTIC TILE, rough CONSTRUCTIONAL TILE, is used for the exposed surfaces.

Vaults. Vaulting in buildings of moderate cost is frequently l by suspending from the roof-trusses STEEL OR WOODEN FRAMES th and plaster. The roof-trusses must in this case be designed to lirect loads of the FRAMED VAULTING, which must be of the required d shape to carry and fit the plastered surfaces.

HEATING AND VENTILATION OF BUILDINGS *

By

LOUIS A. HARDING

RLY PROFESSOR OF MECHANICAL ENGINEERING, PENNSYLVANIA STATE COLLEGE

Physical Units and the Measurement of Heat

m of Units. In this country the system of units in general use by is known as the FOOT-POUND-SECOND SYSTEM, and the following defini- examples will show the significance of each.

tion of Units Employed. The UNIT OF TIME is the second, which is $\frac{1}{86\,400}$ part of the mean solar day. t = time. Time is also expressed in und hours.

ngth. The UNIT OF LENGTH is the foot = 0.3048 meter.

eight. The UNIT OF WEIGHT is the pound = 0.4532 kilogram.

rea. The UNIT OF AREA is the square foot. The unit often used is the square inch.

olume. The UNIT OF VOLUME is the cubic foot. Volume = area $\times$ length $= A \times L$.

tions involving the quantity of air required Q is often used for cubic

e. The volume displaced per stroke by the plunger of a pump, if the is 6 in and the stroke is 12 in, is $\frac{1}{4} \times \pi \times 6^2 \times 12 = 339.29$ cu in, ı ft.

lunger makes 30 WORKING strokes (not revolutions) per minute, then r-DISPLACEMENT per minute is $0.196 \times 30 = 5.88$ cu ft. One United lon = 231 cu in = 0.1336 cu ft. This pump will therefore theoret- ver 5.88/0.1336, or 44 gal per minute. The actual delivery of the be 10 to 15% less, owing to the SLIP, which is the leakage back through valves, around the plunger, and that due to imperfect filling of the nder on the suction-stroke.

. D = density. The weight of a unit volume (1 cu ft) of a sub- lled its DENSITY. The density of water at 70° F. is 62.3 lb per cubic density of air at 70° is .075 lb per cubic foot. The pump in the pre- mple would, therefore, handle 5.88×62.3 or 366 lb of water per

ter-end of the pump is operated by a steam-cylinder having a dis- of 0.349 cu ft per stroke, and takes steam at the same pressure for ke as in the DIRECT-ACTING type and if we assume that the steam- 100-lb gauge, we find from the steam-table (Table I), that the team at this pressure is 0.2565 lb. The STEAM-CONSUMPTION of the efore, would be $0.2565 \times 0.349 \times 30 \times 60 = 161.6$ lb per hour, . A fan handling 10 000 cu ft per minute of air at 70° F, delivers 75 = 100 lb per minute.

v = velocity. The RATE OF MOTION of a body is measured by the sed over in a unit time. Velocity is expressed in feet per second.

the data of this section has been condensed from Vol. I of Mechanical Buildings, by Harding and Willard, published by John Wiley & Sons, Inc.

Energy or Work. U = ENERGY OR WORK. The UNIT OF WORK is the f pound, and is the quantity of energy expended or the work performed by a f of 1 lb moving through a distance of 1 ft in the line of action of the force.

Power is the RATE OF DOING WORK. Note that POWER involves the fa TIME and is equal to the amount of work done divided by the time require do this work.

Horse-Power. h.p. = HORSE-POWER. The UNIT OF POWER is the ho power and is the performance of work at the rate of 550 ft-lb per second 33 000 ft-lb per minute.

Example. Required the theoretical work and horse-power developed by water-end of the pump in the preceding example, assuming that the head or height pumped against is 200 ft, and that no frictional resistance is to be ov come.

The work Um performed per minute is the lifting of the weight of water, 366 lb per min, through a height of 200 ft and is $Um = 366 \times 200 = 73\ 200$ f per min. The h.p. $= Um/33\ 000 = 73\ 200/33\ 000 = 2.22$.

The actual power required will be somewhat greater, as the force requi to overcome frictional resistance, etc., has been neglected.

Equivalent Values of Electrical and Mechanical Units

1 horse-power..	746 watts 0.746 kilowatt 33 000 ft-lb per min 550 ft-lb per sec 2 546 Btu per hr	1 kilowatt	1 000 watts 1.34 h.p. 2 654 200 ft-lb per h 44 240 ft-lb per min 737.6 ft-lb per sec 3 414.5 Btu per hr

Measurement of Pressure. It is customary to measure PRESSURE by me of GAUGES which, in reality, only indicate the difference between the pres being measured and the pressure of the atmosphere, BAROMETRIC PRESSU at the same time and place. These gauges may indicate either a higher or lo pressure than that of the atmosphere; in the former case they are know PRESSURE-GAUGES and in the latter as VACUUM-GAUGES or DRAFT-GAUGES.

Pressure-Gauges and Vacuum-Gauges. The most common type of pr sure-gauge (Fig. 1) is provided with a flexible hollow brass tube of oval cr section known as BOURDON TUBE. When s jected to pressure, this tube tends to straigh out; and this causes a sector of a gear to m with a small pinion, which is on the same sh with the indicating hand or pointer, and ro the latter a corresponding amount. The poi is placed just in front of a graduated dial, shown in the figure, from which the press may be read in suitable pressure-units, such pounds per square inch. These gauges may be used for indicating vacuum, or a pressure than that of the atmosphere.

Fig. 1. Single-spring Pressure-gauge. Interior View

Draft-Gauges. The measurement of press but slightly above or below the atmosph pressure, barometric pressure, is usually accomplished by the use of a DRA GAUGE. This is essentially a U tube, containing either water, kerosene, a hol, or mercury, mounted upon a graduated scale, and reading either in inc of fluid or in pounds or ounces per square inch. Since the pressure indica

ferential one, due to the left-hand leg being open to the air, the reading : obtained by adding the depression in the left-hand leg to the elevation ight-hand leg, using zero as the reference-point in both cases.

neters. The PRESSURE OF THE ATMOSPHERE is usually measured by a IAL BAROMETER (Fig. 2), which, in its simplest form, consists of a glass out 3 ft long, closed at one end. After led with mercury it is inverted in a shallow mercury. The pressure of the atmosphere evel maintains the mercury-column in the out 30 in above the level in the bath or The barometric height or length of this of mercury varies with the altitude above sea-level. When the mercury in the tube t in the cistern rises in corresponding pro- and vice versa, so that there is an ever- relation between the level of the mercury ube and the mercury in the cistern, which he accuracy of the readings. It is, there- essary, before reading the height of the column on the stem of the barometer by f a movable vernier, to adjust the level of ury in the cistern. All standard or observ- ometers of the mercurial type have this nt. Barometers of other types, such as ROID BAROMETER, must be frequently l with a standard mercurial barometer in check the accuracy of their readings.

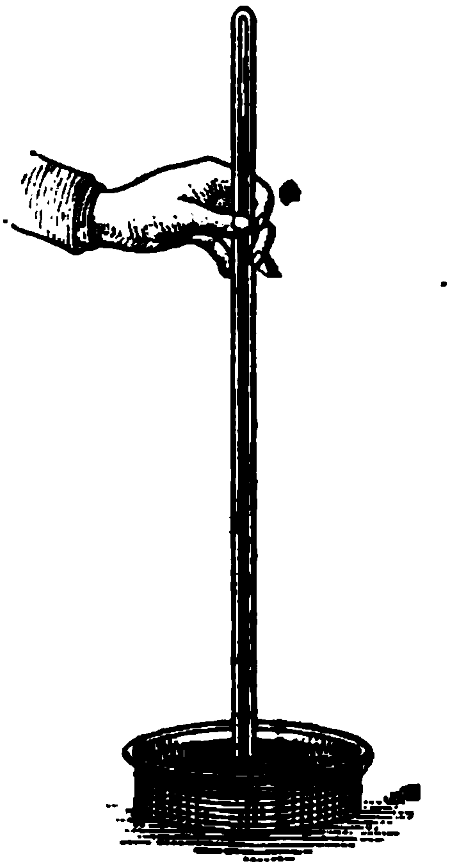

Fig. 2. Simple Barometer

etric Pressure. By BAROMETRIC HEIGHT is meant the height of a f pure mercury at 32° F. which just balances the pressure of the atmos- the time and place of the observation. The STANDARD OR NORMAL IIC PRESSURE is defined as the pressure of a column of pure mercury (29.92 in) high at 32° F. This is the normal barometric pressure at 5° and at sea-level. Since the weight of 1 cu in of mercury under e conditions is 0.491 lb, the normal barometric pressure = height of olumn × weight per cubic inch = 29.92 × 0.491, or 14.7 lb per iis pressure of 14.7 lb per sq in is known as the ABSOLUTE PRESSURE nosphere at latitude 45° and at sea-level. Now, since the ordinary auge measures only pressures above or below that of the atmosphere, sary to ADD THE BAROMETRIC PRESSURE at the place in question TO E-READING TO OBTAIN THE TOTAL ABSOLUTE PRESSURE corresponding sure indicated by the gauge. That is, absolute pressure = barometric - gauge-pressure.

Heat

on of Heat. HEAT IS A FORM OF ENERGY. It is, in fact, the kinetic ial energy of the molecules of which all substances, whether solid, aseous, are composed. Whenever the vibratory motion of the mole- osing a body of given mass is increased from any cause the THERMAL IERGY is increased. The temperature of the body rises, its SENSIBLE ases, and the body feels warmer.

ement of Temperature. Thermometry. INTENSITY OF HEAT is by THERMOMETERS and PYROMETERS, the latter being used for high es above from 400° to 500° F. In engineering work mercurial

thermometers are very largely employed. These depend upon the unif expansion of mercury to indicate changes in temperature. The UNIT OF MEASU MENT is called a DEGREE, and is capable of very exact determination, provi that two points, at which the heat-intensity is always constant, can be use bases or references for calibration. The melting-point of ice and boiling-p of water at atmospheric pressure are usually selected as bases, and the unif expansion of the mercury between these two points is indicated on a s divided into 180, 100, or 80 divisions. (Fig. 3.) Each of these division known as a DEGREE and the scales used are known spectively as FAHRENHEIT, CENTIGRADE or CELS and REAUMUR. The Fahrenheit is used almost ex sively in engineering in this country.

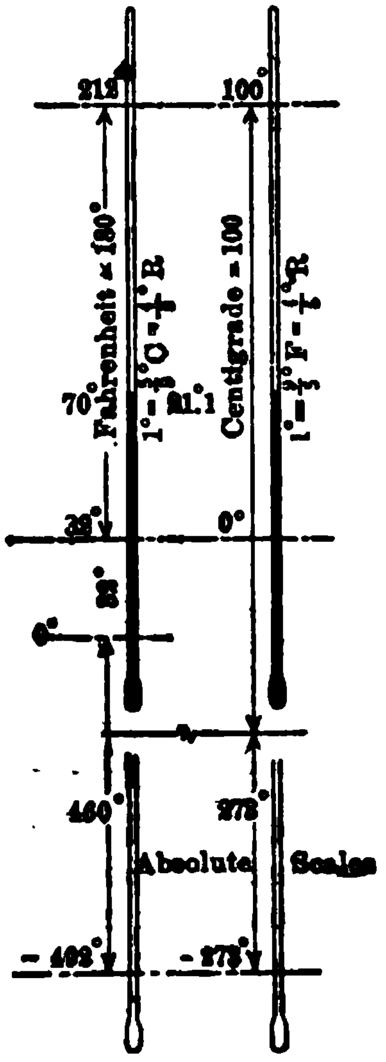

Fig. 3. Fahrenheit and Centigrade Thermometers

Absolute Temperature. In addition to the t temperature-scales already described, physicists em what is known as the ABSOLUTE SCALE OF TEMPE TURES, based on the so-called ABSOLUTE ZERO OF T PERATURE, at which point no molecular vibration ex This zero is conceived as 491.6° F. below the melti point of ice (32° F.), it having been discovered tha ideal perfect gas would change in volume by 1/4 of its volume at 32° F. for each 1° change in its t perature, at constant pressure. Thus, if 491.6 c of gas, measured at 32° F., is cooled 20° F. at const pressure, the new volume will be 471.6 cu ft. I only necessary to add 491.6 − 32, or 459.6, to actual thermometer-reading to get the absolute t perature. That is, $T = t + 459.6$, where T = abso temperature, and t = actual thermometer-reading the Fahrenheit-scale. For engineering-work, 460° used rather than 459.6°. For the Centigrade scale relation is $T = t + 273.1$.

Measurement of Heat-Quantity. Calorime HEAT MAY BE MEASURED, since it is a form of ener in any of the usual energy-units, as the JOULE, FO POUND, or HORSE-POWER HOUR. It is the custom, h ever, to use for this purpose a special unit more rea applicable to heat-changes. This unit in the English system is known as BRITISH THERMAL UNIT (Btu), and is the amount of heat required to raise 1 l water from 63° to 64° F. For all practical purposes in ordinary calculatio Btu is the amount of heat required to raise 1 lb of water 1° F.

Specific Heat. It is a well-known fact that equal quantities of heat raise equal weights of different substances a different number of degrees, depe ing on the nature of the substances. This property of matter is know SPECIFIC HEAT, and for any substance can be expressed as the number of required to raise or lower the temperature of 1 lb 1° F., at some given t perature. It is also customary to make use of the mean or average value a certain temperature-interval. Two specific heats are recognized, one kn as the TRUE SPECIFIC HEAT, measured at the temperature stated, and the o as the MEAN SPECIFIC HEAT, which is the average value between the temperat under consideration. The specific heat of air at constant pressure is 0.24.

Relation between Units of Energy and Power. Since the various form energy, heat, mechanical energy, electrical energy, etc., are mutually conv ible, there must be definite numerical relations between the various units

ess energy. As determined by various physicists the relation between
ı and the ft-lb is

$$1 \text{ Btu} = 777.64 \text{ ft-lb}$$

umber 777.64 is called the MECHANICAL EQUIVALENT OF HEAT and is
l by J. For ordinary use the value 778 may be taken. Another con-
relation is,

$$1 \text{ h.p.} = 2\,564 \text{ Btu per hr}$$

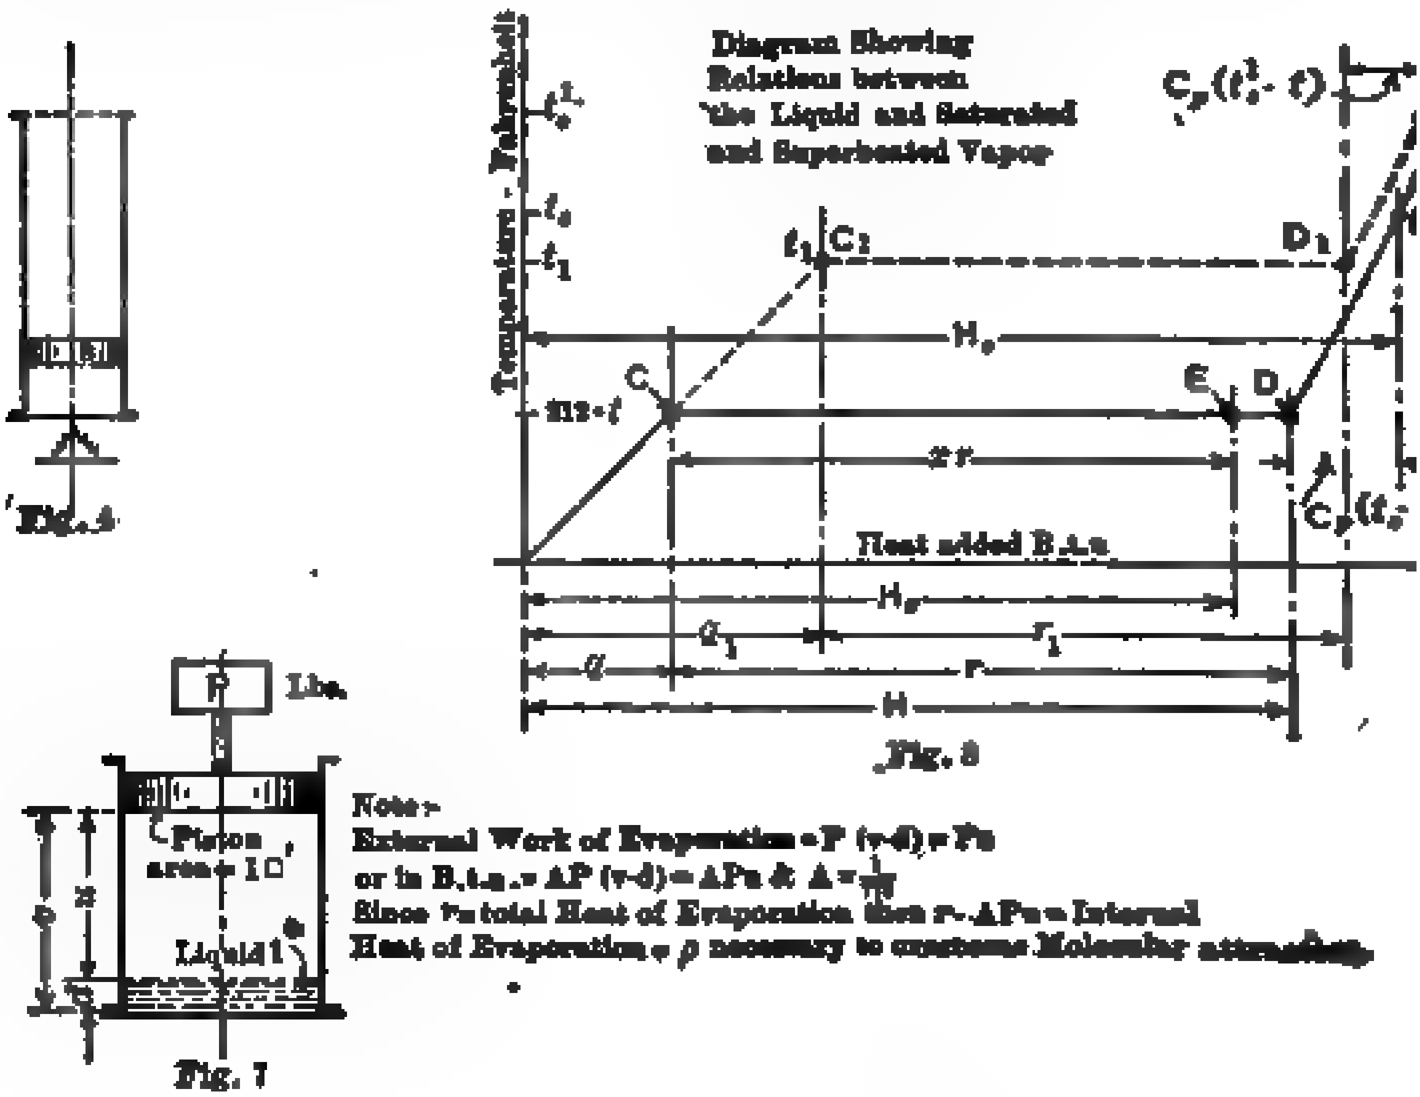
Steam

rties of Steam. Steam is water-vapor, which exists in the vaporous
n because sufficient heat has been added to the water, from which the
as been formed, to supply the latent heat of evaporation, and to change
id into a vapor. This change of state takes place at a definite and
temperature, which is determined solely by the pressure of the steam.
e in pressure will always be accompanied by a change in the tempera-
which ebullition or boiling will occur, and there will be a corresponding
n the latent heat. The properties of steam, together with other char-
s, are tabulated in the steam-tables. (See Table I.) Steam in con-
t the water from which it has been generated is known as SATURATED
nd may be known as DRY SATURATED STEAM, or as WET SATURATED
The latter contains more or less actual water in the form of mist or
as it is called. If dry, saturated steam be heated, and the pressure
ed the same as when it was vaporized, its temperature will increase
ll become SUPERHEATED; that is, its temperature will be higher than
turated steam at the same pressure.

le and Latent Heat. Whenever heat is added to a substance, without
state, its temperature is raised, and the heat thus added is known as
HEAT, as, for example, the heat added to water the temperature of
etween 50° and 140° F. Sensible-heat changes, as already stated, are
by the thermometer. Heat may be added to a body without any
temperature provided a change of state from solid to liquid or from
apor takes place, and the heat thus added is known as LATENT HEAT.
change is from solid to liquid, as from ice to water, this heat is known
ENT HEAT OF FUSION. At atmospheric pressure ice melts at 32° F.,
ent heat is 144 Btu per lb. When the change is from liquid to vapor,
ter to steam, the heat required to effect the change is known as the
AT OF EVAPORATION. At atmospheric pressure water evaporates at
nd the latent heat is 971.7 Btu per lb. A conception of the relation
e properties or characteristics of steam, and the manner in which the
state, temperature and pressure are brought about, is described in the
aragraphs.

ion of Steam. Consider a frictionless cylinder (Fig. 4), containing
er at 32° F. Also consider the pressure of the atmosphere to be 14.7
and to be replaced by that of the piston B. When heat is applied
der the temperature of the water rises until the boiling-point, 212° F.,
The heat necessary to raise the temperature from 32° F. to the
it is known as the HEAT OF THE LIQUID or SENSIBLE HEAT, and is de-
e symbol Q. This condition is denoted in Fig. 8 by the point C.
e specific heat of water between 32° F. and 212° F. is 1; hence the
British thermal units (Btu) necessary to raise the temperature of
his amount is 212 − 32 or 180 Btu.
re heat is added the water begins to evaporate and expand at con-

stant temperature until, as in Fig. 6, the water is entirely changed into steam. This condition is also shown in Fig. 8, by the point D. The heat thus added known as the LATENT HEAT OF EVAPORATION and is denoted by the symbol This heat r is subdivided into two parts. (See Fig. 7.) First the attractic between the molecules must be broken down. This is known as the INTERNA LATENT HEAT and is denoted by the symbol ρ. Next the external resistan must be overcome, the weight P being raised against gravity. The heat th added is known as EXTERNAL LATENT HEAT and is designated by the symbo APu, where u is the change in volume, in cu ft of 1 lb of water, A is 1/778, an



Figs. 4 to 8. Diagrams Explaining the Generation of Steam

P is the pressure of the atmosphere in pounds per square feet (barometr pressure). It is evident then that the latent heat

$$r = \rho + APu, \text{ or } \rho = r - APu$$

The term APu is the heat-equivalent of the work performed for the change i volume from water to steam.

The heat added from the starting point (32° F), is known as TOTAL HE (H), or $q + r = H$. If more heat is added, the pressure remaining constan the temperature of the steam rises and the steam becomes what is known SUPERHEATED STEAM. The heat added is equal to the MEAN SPECIFIC HE (C_p) of the steam, times the change in temperature ($t_s - 212$). The speci heat of steam is the Btu, or heat, required to raise the temperature of 1 lb of th steam 1° F. Since the specific heat of steam is less than that of water, th slope of this line becomes greater than that of the water-line The point now located at t_s (Fig 6), and the steam has increased in volume in the cylind (Fig 5), until the piston occupies the dotted position B'.

If instead of the above condition of pressure, additional pressure is adde

rom original tables published by John Wiley & Sons, Inc.

as shown by the weight W in Fig. 6, the temperature of the boiling-point will raised from the temperature of 212° F. to some other point, as t_1 (Fig. 8). may be seen by this figure, the sensible heat q has been increased to q_1. Wh more heat is added the water is evaporated at the temperature t_1, and if he again be added the SATURATED STEAM will become SUPERHEATED STEAM.

Quality of Steam. The proportion of the DRY STEAM, per pound of ste delivered by the boiler, is known as the QUALITY OF THE STEAM and is rep sented by the symbol x, and the heat (H_x) contained in the steam above 32° is $q + xr$; the state-point is located at E (Fig. 8).

Specific Volume and Density. The volume of a pound of steam is kno as the SPECIFIC VOLUME v, and as may be seen by comparing Figs. 5 and 6, creases as the pressure increases. The reciprocal of this, or the weight of ste per cubic foot, is known as the DENSITY, and is denoted by d or $1/v$.

Entropy. Another quantity known as ENTROPY is made use of in calcu tions relating to steam-engines and turbines, and is defined as the ratio obtain by dividing the quantity of heat added to a substance by the absolute tempe ture at which it is added.

The Total Heat, H, of a dry, saturated vapor for any pressure and te perature is the sum of the heats required to raise the temperature of one pou of the liquid from the freezing-point to the given temperature and correspondi pressure and ENTIRELY VAPORIZE IT at this pressure. For this case $x =$ and consequently

$$H = (\rho + APu) + q = r + q$$

The total heat (H_x) of wet vapor at any pressure and temperature is

$$H_x = xr + q$$

It is manifestly incorrect to say that this is the heat in the vapor, as the A is not the heat in the vapor, but the external work performed by the vapor wh evaporating.

Superheated Steam or Vapor. Superheated steam is defined as water-va which has been heated out of contact with its liquid, until its temperatur higher than that of saturated vapor at the same pressure.

The heat-content of superheated steam or vapor may be expressed by equation

$$H_s = q + r + C_p(t_s - t) = H + C_p(t_s - t)$$

where t_s is the temperature of superheated vapor, t the temperature of satura vapor at the corresponding pressure, q the heat of the liquid at t, an the heat of vaporization at temperature t. C_p is the mean specific heat superheated vapor (approximately 0.50), H the total heat of 1 lb of dry urated steam, and H_s the total heat of 1 lb of superheated steam.

Properties of Air

Charles' Law. Charles' Law refers to the relation between pressure, vol and temperature of a gas, and may be stated as follows. The volume given weight of gas varies directly as the absolute temperature at cons pressure, and the pressure varies directly as the absolute temperature at cons volume. Hence, when heat is added at constant volume V_c, this equation res

$$\frac{P_2}{P_1} = \frac{T_2}{T_1}$$

: temperature-range, at constant pressure P_0, the relation is

$$\frac{V_2}{V_1} = \frac{T_2}{T_1}$$

or any weight of gas M, since volume is proportional to weight at ıme and temperature,

$$PV = MRT$$

ıaracteristic equation for a perfect gas. In this formula

bsolute pressure of the gas in pounds per square foot = 2116.8 ıtmospheric pressure);
'olume of the weight M in cubic feet;
veight in pounds of the gas taken;
ıstant depending on the nature of the gas = 53.37 for air;
ıbsolute temperature in degrees Fahrenheit (t + 459.6).

A PERFECT GAS conforms exactly to the above equation, and while no gases PERFECT in this sense, they conform so nearly that the above equation app to most engineering-computations. The volume of 1 lb of air, known as SPECIFIC VOLUME, at any temperature and pressure, can be found at once the equation

$$V = (53.37 \times T)/P$$

Estimating Heating Requirements of Buildings

Heat Required and Supplied. The amount of heat, measured in Btu to supplied by the heating-apparatus to a building to maintain the inside tempe ture above that of the outside, commonly termed HEAT-LOSSES, is:

(a) The heat required to offset the heat-transmission of the walls, ceilin roof, and floor. This loss of heat depends upon the type and materials of c struction used and the temperature-difference to be maintained between inside and the outside of the building.

(b) The heat required to warm the air entering the building from the outsi either by infiltration or purposely introduced for ventilation.

(c) The heat supplied by persons, lights, machinery and motors, which m be deducted from the sum of items (a) and (b) to obtain the net amount of h to be supplied by the heating-apparatus. (Item (c) is usually not considere

It is customary in all calculations connected with the design of heati installations to base the estimate on the amount of heat per hour to be suppl by the apparatus. The total heat to be supplied per hour is H = [(item a) (item b) − (item c)] Btu. The method in use for the calculation of the vari items above mentioned will now be taken up and discussed in the order give

Temperatures. The inside temperature to be maintained and the air quired for ventilation for various classes of work are discussed under Ventilati to which the reader is referred. The outside temperature for which the heati installation should be designed is fixed by the lowest outside temperature t is liable to continue for several days during the heating-season.

Usual Inside Temperature Specified

Kind of buildings	Degrees F.
Public buildings	68–72
Factories	65
Machine-shops	60–65
Foundries, boiler-shops, etc.	50–60
Residences	70
Bath-rooms	85
Schools	70
Hospitals	72–75
Paint-shops	80

In designing the heating-system a temperature of from 10° to 15° F. hi than the lowest recorded temperature is recommended to be used for the side temperature.

Heat-Transmission of Walls, Ceilings, Roofs, Floors, etc. (a) The h loss through building-construction is dependent upon the character of material, thickness and character of the surfaces, and the velocity of th over the surfaces. Numerous tests have been conducted by various ex menters to determine accurately the heat-transmission of various type

; in thick with 5-ply tar and felts..........	0.633

mission of stone walls is approximately 50% greater than that thickness. The Btu-loss per foot of sash-perimeter is based on minations by Voorhees and Meyer, Trans. Am. Soc. H. and

ssion of Roofs and Floors. The temperature of the air in under side of a ceiling or roof is found to be higher than the ntained at the breathing-line, at which point the temperature ed; and this is due to the natural tendency of the warmer or ise. It is recommended that an increase of approximately the specified inside temperature for the temperature at the or wall-heights not exceeding 15 ft, and 30% for ceiling-heights n estimating the heat-loss of roofs. Thus, if 65° F. is the spe- perature to be maintained in a room the height of which is ature of the air in contact with the under side of the roof may : 65° + 30%, or 85° F. The loss of heat through the ceiling which a large air-space exists, through partitions between a room, or through the first floor to the cellar, may be estimated n that the warmed rooms give off sufficient heat to maintain of these colder spaces according to the following schedule:

cs under metal or slate roofs.................	14° F.
cs under tile, cement, tar, or gravel roofs......	23° F.
l rooms kept closed.........................	35° F.

nission of floors that are laid directly upon the ground may be assumption that the ground in contact with the under side of pproximate temperature of 50° F. Thus the estimated heat- in concrete floor laid directly upon the ground, assuming an e of 65° F., is

;3 (65 − 50) or 8.4 Btu per square foot per hour

Infiltration. (b) The heat required to warm the outside air

which may enter by LEAKAGE through the cracks or clearances around windo and doors is that required to raise the temperature of the weight of incomi air per hour from the outside to the inside temperature.

Let b = Btu required per hour to heat the incoming air;
t = inside room-temperature in degrees Fahrenheit;
t_0 = outside temperature;
C_p = specific heat of air at constant pressure = 0.24;
d = density of the air at temperature t;
= 0.075 for 70° inside temperature;
= 0.076 for 60° inside temperature;
Q = cubic feet of air per hour entering building by infiltration, measu at temperature t;
W = weight of air per hour entering building by infiltration $= d \times Q$;

Then $b = C_p\,(t - t_0)\,Q \times d = 0.24 \times W \times (t - t_0)$;
$= 1.26\,Q$ for 70° inside temperature;
$= 1.08\,Q$ for 60° inside temperature.

There are two assumptions made by engineers in practice for obtaining th value of Q. The common method in vogue is to assume a certain number o air-changes n, per hour in the cubical contents C, of the room in accordanc with the following table:

Table VI. Number of Air-Changes per Hour

Halls	$n = 3$
Rooms on 1st floor	$n = 2$
Rooms on 2nd floor	$n = 1$
Offices and stores, 1st floor	$n = 2$ to 3
Offices and stores, 2nd floor	$n = 1\frac{1}{2}$ to 2
Churches and public assembly-rooms	$n = \frac{1}{4}$ to 2
Large rooms with small exposure	$n = \frac{1}{2}$ to 1
Factory-buildings	$n = \frac{1}{2}$ to 1

Example. Required the heat-loss, by infiltration, from a room containin 20 000 cu ft, the temperature of which is maintained at 7c° F. in zero weathe the estimated number of air-changes n, being two per hour.

Solution. $Q = 2 \times 20\,000 = 40\,000$ cu ft of air entering per hour measure at 70° F.

$b = 0.018 \times 40\,000 \times (70 - 0) = 50\,400$ Btu per hour.

The other method is to use the estimated amount of air-leaking in the build- ing through the cracks around the sash-perimeter and meeting-rail. The fol- lowing data may be used in this connection and is based on a wind-movement o approximately 20 miles per hour (Voorhees and Meyer Tests).

Plain wooden sash	114	cu ft air per hour per foot perimete
Plain wooden sash, weather-stripped	24	cu ft air per hour per foot perimete
Hollow metal sash	216 to 268	cu ft air per hour per foot perimete
Hollow metal sash, weather-stripped	72 to 150	cu ft air per hour per foot perimete
Copper-covered sash	132	cu ft air per hour per foot perimete

For a room with more than one outside wall use only the sum of the per- imeters of the windows, in the side having the greater number.

the Btu equivalent of 1 horse-power hour. In high-powered
ief source of heating and is sometimes sufficient to overheat
n zero weather, thus requiring cooling by ventilation the year

or Estimating the Heat-Loss of Buildings. There is
RULE-OF-THUMB METHODS for estimating the heat-loss H
the heating-surface required when direct radiation is to be

used. These so-called practical rules are intended to be based on aver building-construction and on the ratio of wall and glass-surface to the cubi contents as found in buildings of the class to which they refer. These ru when modified for unusual conditions and applied by engineers of long expe ence in the proportioning and design of heating systems produce satisfact results. They are, however, rapidly being discarded except as rough che on the more refined methods of calculation.

Carpenter's Rule. The following formula, or rule, which has been wid used for many years in this country, was proposed by R. C. Carpenter. It

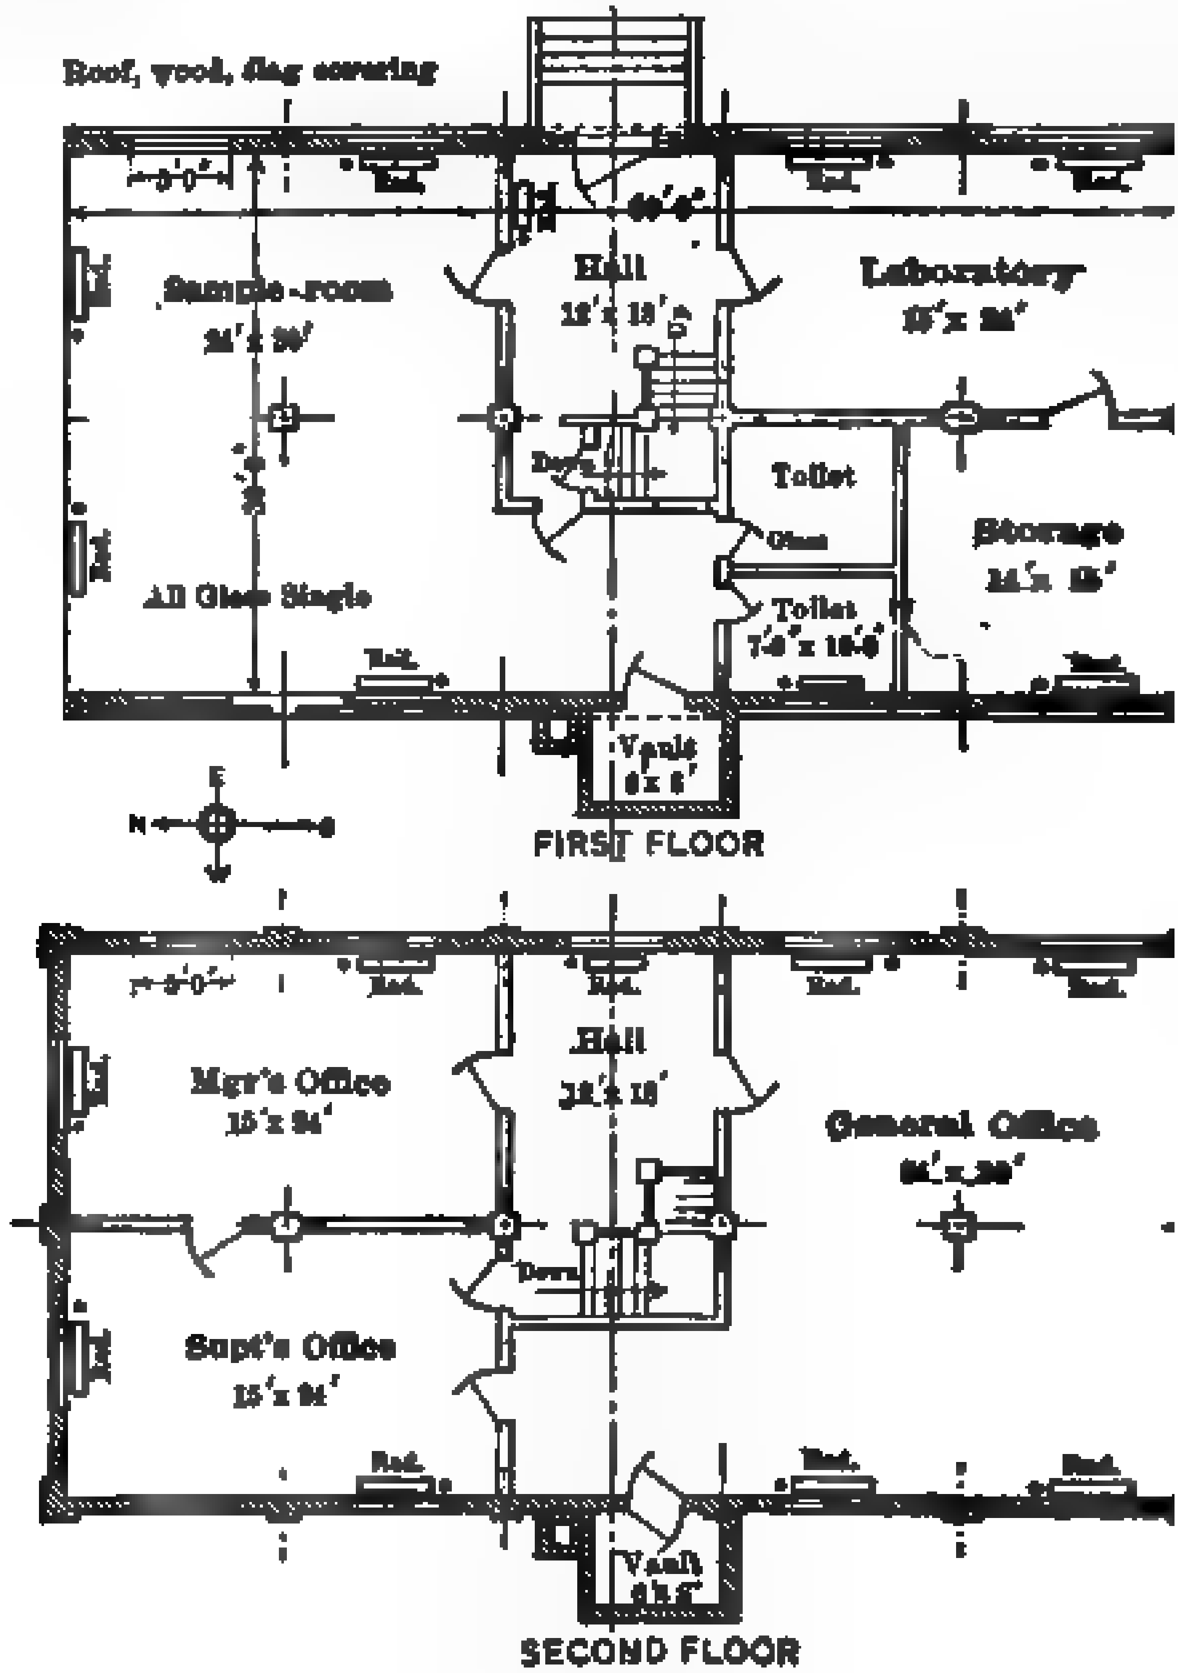

Fig. 9. Floor-plans and Section of Building Explained in Table VII. (See, also, Fig.

not intended to be applied to buildings covered with corrugated sheet steel metal lath and plaster walls, unless the wall-constant is changed to suit the c dition.

By reference to Table IV, it will be noted that a fair average value for t heat-transmission of the usual well-constructed building-wall is approximat

.25 Btu and for glass 1.0 Btu per degree difference between the inside and outside temperature per hour.

Professor Carpenter states that usually we may, with sufficient accuracy, neglect all inside walls, floors and ceilings and consider only the outside walls.

The estimated number of air-changes per hour, by infiltration, has already been given in Table VI.

Let C = cubical contents of room in cubic feet;
n = number of air-changes per hour (see Table VI);
0.02 = Btu to raise 1 cu ft of entering air 1° F.;
W = net wall-surface in square feet;
G = glass-surface in square feet;
$(t - t_0)$ = temperature-difference between inside and outside;
H = total heat to be supplied per hour in Btu;
$H = (0.02nC + G + \frac{1}{4}W)(t - t_0)$.

Calculating the Heat-Loss of a Building. The following example (Tal VII) will serve to illustrate the method employed in calculating and tabulati the heat-loss of a typical building, the floor-plans and section being shown in F 9. (See, also, Fig. 34.) The heating requirements are for a temperature of 70° in zero weather. The heat-transmission for the outside walls per square fo is taken from Table IV for a temperature-difference of 70°. The heat-lo through the first floor is based on a temperature-difference of 70 − 35 or 35 The heat-transmission per square foot per 1° difference in temperature p hour for 1¼-in wood is 0.37; hence for 35° it is 0.37 × 35 = 13 Btu per hou The heat-loss through the ceiling of the second floor is based on a temperatu difference of 70 − 23 = 47°, 23° being the assumed temperature of the att in zero weather. The heat-transmission per square foot per hour is therefo 47 × 0.40 = 18.8 Btu. The infiltration-loss is, in this example, based on t estimated number of air-changes per hour as indicated in Table VII.

By Carpenter's rule the heat-loss of this building based on two air-chang per hour, is

$$[0.02 \times 2 \times 41\,730 + (3\,464/4) + 730] \times 70 = 228\,564 \text{ Btu per hour}$$

Radiation

Direct Radiation. Steam or hot-water radiators placed in the room to b heated are termed DIRECT RADIATORS or DIRECT RADIATION. Common typ of direct radiators are shown in Figs. 10, 11, 12 and 13.

Indirect Radiation. Radiators used to warm the air passed over them, t heating of the building being accomplished by hot air, are termed INDIRE RADIATORS or INDIRECT RADIATION. (See Figs. 45 and 46.) This type radiation is frequently used for installations in which provision must be ma for ventilation as well as heating, as in the case of schools, public buildings, et Indirect radiation is also used to some extent in high-grade residence-heati where direct radiation may be thought unsightly, particularly for the first flo Direct radiation is ordinarily employed for the floors above the first floor. T principal use of indirect radiators is in connection with the HOT-BLAST SYST of heating, described later, in which a fan is used to circulate the air over t radiator and through the duct system.

Direct-Indirect Radiation. DIRECT-INDIRECT RADIATORS (Fig. 14) a radiators placed in the rooms to be heated and furnished with a cold-air co nection through the outside wall. It serves the purpose of providing te pered-air ventilation.

Materials and Connections of Radiators. Radiators are constructed cast iron, pressed steel or pipe-coils. The sections for one-pipe steam syste are connected only at the bottom. The sections for hot-water radiators a two-pipe steam systems are connected at both top and bottom. The latt is known to the trade as HOT-WATER RADIATION.

adiation. Cast-iron radiators should not be operated above ssure. Standard pipe-coil direct radiation, up to 125 lb.

ators. Radiators are rated according to the square-foot area ıg-surface. Cast-iron and pressed-steel direct radiators are ns. The amount of heating-surface per section of cast-iron various standard heights manufactured is given in Table VIII.

ree-column Radiator **Fig. 11. Peerless Three-column Radiator**

Direct Cast-Iron Radiator. The American Radiator Complaced on the market a new type of direct cast-iron radiator proximately 30% more heating-surface for a given floor-area is is than with other types of direct radiation. The length of and the width 8 in for all heights.

ace per section is as follows:

38-in, 4½ sq ft	34½-in, 4 sq ft	31-in, 3½ sq ft
23-in, 2½ sq ft	19⅓-in, 2 sq ft	

Fig. 12) is largely used in bath-rooms, and also for factory- e width of column-type radiation is objectionable. (See g and dimensions.)

Radiators.* These radiators have been developed in recent st ingeniously fabricated of No. 20 United States standard- ets made into shapes, widths and heights which correspond h the cast-iron column-radiators. Each section is made up of joined by a double-lapped seam and the separate sections single-lapped seams. The pipe-connection is made into a e-iron ring secured to the end-section by rolling the sheet

d by the Pressed Metal Radiator Company, Pittsburgh, Pa.

* Peerless 15-in in steam only.

The location of the figures in the above columns in line with the names of patt of radiators indicates the heights in which the various patterns are made. The figu themselves represent the amount of heating-surface contained in each section.

To obtain the total length of the radiator, multiply the length per section by the nu ber of sections.

given increase or decrease in the temperature-range above -tandard range. An examination of test-data so far avail-

able seems to indicate, that this variation is nearly 0.2% per degree above below the standard range of 150°. Thus, if a three-column, 38-in high, dir radiator is to be used in a room kept at 60° F., with steam at 230°, we wo have a temperature-range of 170° or 20° above standard, and the value of would become

$$K = (1.55 + 0.002 \times 20 \times 1.55) = 1.61$$

and each square foot of radiation would give off $1.61 \times 170 = 274$ Btu per

Table XI. Values of K for Direct Radiators

* Air entering flues at 70° F. and leaving same at 152° F. Allen.

K increases (1) as height of radiator is reduced and (2) as number of columns width of radiator decreases.

Coefficients of Transmission for Direct Hot-Water Radiators. Table may be used for values of K for hot-water radiators of the same type as th listed, but allowance should be made for the lower temperature-range in h water heating. Thus, with a room usually at 70° F., and water at 180° enteri and at 160° leaving the radiator, the temperature-range is only 100°, or 50° l than the standard range. Then for a two-column 26-in high direct radiat the value of K becomes

$$K = (1.75 - 0.002 \times 50 \times 1.75) = 1.58$$

and each square foot of this radiation gives off, $1.58 \times 100 = 158$ Btu per h

Concealed Radiators. The effect of placing a grill in front of a dir radiator, with a cover over the top, reduces the heat-emission by approximat 20%. A clear space between the radiator, wall and enclosure should not less than 2½ in. Concealed radiators are not looked upon with favor from strictly sanitary point of view.

The Usual Assumptions Made for the Heat-Transmission of Dir Radiation is 250 Btu per sq ft per hr for low-pressure steam (2 lb) cast-iron ra ators, and 150 Btu per sq ft per hr for cast-iron hot-water radiators with t water at 180°. The square-foot rating of heating-boilers is based on the abo figures. For more exact values use the data given in Table XI. According a hot-water installation requires 66⅔% more radiation than a low press steam system.

Example. It is required to determine the amount (R) of direct cast-ir radiation, low-pressure steam and hot water, to supply a heat-loss of

$$H = 10\,000 \text{ Btu per hr}$$

tion. For the direct steam system

$$R = H/250 = 40 \text{ sq ft}$$

a direct hot-water system

$$R = H/150 = 66\tfrac{2}{3} \text{ sq ft}$$

ee-column cast-iron radiator, 38 in high, is to be used, the heating-surface h is 5 sq ft per section, it will require $40/5 = 8$ sections for the steam-job, the length of radiator equal to $8 \times 2\frac{1}{2} = 20$ in.

Fuels and Combustion

ification of Fuels. Fuels are generally classified as solid, liquid, and . SOLID FUELS are coal, wood, and wastes. LIQUID FUELS are petroleum products. GASEOUS FUELS are natural and artificial gas.

Fields in the United States. Most of the anthracite is found in beds han 500 sq miles in area located in eastern Pennsylvania. The prin- posit of semibituminous coal is about 300 miles long by 20 miles wide along the eastern edge of the Northern Appalachian field. The bitumi- ls extend from this deposit westward. A little graphitic coal is found Island.

osition of Coal. The uncombined carbon in coal is known as FIXED Some of the carbon-constituent is combined with hydrogen, and this, with other gaseous substances driven off by the application of heat, t portion of the coal known as the VOLATILE MATTER. The fixed carbon olatile matter constitute the COMBUSTIBLE. The oxygen and nitrogen l in the volatile matter are not combustible, but custom has applied to that portion of the coal which is dry and free from ash, thus includ- ygen and nitrogen in the combustible.

ication of Coals. Coals may be classified according to the percentages arbon and volatile matter contained in the combustible.

Table XII. Classification of Coals (Kent)

ous West...	65.0 to 50.0	35.0 to 50.0	13 500 to 14 800
....	50.0 and under	50.0 and over	11 000 to 13 500

etric Determinations. The only accurate and reliable way to deter- eating-value of a fuel is to do so experimentally with a calorimeter. uels, the BOMB-CALORIMETER is the most practical. The various types ket include the Mahler, the Hempel, the Atwater and the Emerson. ist essentially of a tight vessel containing a weighed sample and oxygen sure. This receptacle is placed within another vessel containing a ght of water and surrounded by heat-insulating material to minimize

radiation. The sample is EXPLODED electrically, and the heat absorbed by surrounding water is determined by means of a very accurate thermome reading hundredths of a degree. Correction has to be made for the heat sorbed by the instrument itself, and for radiation.

For a complete description of calorimeters and their use, see Carpenter Diederichs' Experimental Engineering.

Calorific Value by Formula. The following expression, known as Du Lo FORMALA for heating-value per pound of coal, can be used if the ultim chemical analysis of the fuel is known:

$$F = 14\,600\,C + 62\,000\,(H - \tfrac{1}{8}O) + 4\,000\,S$$

where C, H, O, and S represent the proportionate parts of each element per of fuel, and F denotes the heat-value in Btu per pound due to combusti This formula does not apply when the fuel contains carbon monoxide, CO, can be made to apply by adding a term, 10 150 C, in which C is the proportion part of carbon burned to the monoxide.

Example. The application of the formula to a coal of ultimate analysis here given follows:

Analysis (based on fuel as received)

C	74.79%
H	4.98
O	6.42
N	1.20
S	3.24
H_2O	1.55
Ash	7.82
	100.00%

Then by Du Long's formula, 14 600 × 0.7479 + 62 000 (0.0498 − 0.0642 + 4 000 × 0.0324 = 13 650 Btu per 1 lb of coal.

A bomb-calorimeter test showed 13 480 Btu for this coal. The formula fa to allow for evaporating and superheating the moisture present in the fuel.

Combustion of Fuel. Combustion, as used in steam-engineering, signifies rapid chemical combination between oxygen, and the carbon, hydrogen, a sulphur composing the various fuels. This combination takes place usually

Table XIII. Theoretical Amount of Air Required for Combustion

Storage. Space for fuel-storage must be based on fuel-con
s estimated under Fuel-Consumption, page 1278, and in
it is customary to proportion the storage-space on the b
area per ton, the storage-space being made ample to h
supply.
llowing volumes per ton of 2240 lb of coal are given for
pace: bituminous coal, 41 to 45 cu ft, and may run as hig
e coal, 34 to 41 cu ft; charcoal, 123 cu ft; coke, 70.9 cu
based on fuel broken down ready for market. Also
lb and 1 bushel soft coal = 76 lb.

Steam-Heating Boilers and Hot-Water Heaters

res, Attention, and Materials. Heating-boilers usually
ER PRESSURE than do power-boilers, and in most cases r
The steam-boilers are usually designed to operate on f
SSURE, and the WATER-BOILERS or hot-water heaters ar
hydrostatic head in excess of 100 FT when in operation.
these boilers is of such an INTERMITTENT CHARACTER t
heating-load for comparatively long periods without
y range from 6 to 10 hrs and in consequence the comb
elatively large grates and fire-pots are necessary. T
for constructing heating-boilers are CAST IRON, espe
es, although boilers of nearly 100 equivalent steam
Rating of Heating-Boilers) are made of this same

STEEL OR WROUGHT IRON, which are more generally used in the larger sizes. T government departments usually specify steel heating-boilers, and they are u extensively in office and loft-buildings as well.

Boiler Heating-Surface. The CAPACITY of any boiler or water-heater depe on the amount of, and the temperatures on the opposite sides of, the he transmitting surfaces in contact with the water in the boiler on one side, and t fire or hot gases on the other. It is most important that a rapid circulation water and the hot gases shall take place over these surfaces, and preferably opposite directions. Two kinds of surface are distinguished in boiler-practi and known as direct and indirect surface. DIRECT SURFACE is that on whi the fire shines, and INDIRECT that in contact with the flue-gases only. All su surface must have water on the opposite side. In some boilers the hot ga are allowed to come in contact with the boiler-surface above the water-li so that there is only steam in contact with this surface on the inner side. Su surface is known as SUPERHEATING-SURFACE in order to distinguish it fr ordinary heating-surface. Direct surface is the more valuable of the two, p square foot, as it is usually subjected to a higher temperature, and furtherm because the intensity of radiation from an incandescent surface appears to va as some power of the temperature of that surface, either the third or fourt

Equivalent Evaporation. The equivalent evaporation of a boiler is t pounds of water the boiler would evaporate per pound of coal burned if received the feed-water at 212°, and evaporated it into steam at this same te perature and pressure, so that the evaporation would take place FROM AND 212° F. In practice the feed-water is usually below this temperature a evaporation actually takes place at some higher temperatrue than 212°. He to find the EQUIVALENT EVAPORATION it is always necessary to make use of t following relation:

$$E = \frac{(x_2r_2 + q_2 - q_1)}{971.7} \times P$$

where the fractional part of the expression is known as the FACTOR OF EV ORATION; so that

$$E = \text{factor of evaporation} \times P$$

E = equivalent evaporation from and at 212° F., in pounds;
x_2 = quality of steam as actually evaporated;
r_2 = latent heat of steam as actually evaporated;
q_2 = heat of the liquid as actually evaporated;
q_1 = heat of the liquid as actually fed to boiler;
P = actual evaporation in pounds per pound of fuel burned;
971.7 = latent heat of steam at 212° F.

Boiler Horse-Power. A boiler horse-power is the energy required to ev orate 34.5 lb of water at 212° F. into DRY STEAM of 212° F., or

$$971.7 \times 34.5 = 33\,524 \text{ Btu}$$

The HORSE-POWER RATING of a boiler is always measured in terms of the equi lent evaporation. Thus, if we divide the EQUIVLAENT EVAPORATION of a bo by 34.5 we get the boiler horse-power developed.

Boiler-Efficiencies. Heating-boilers, operated at their rated capacity, show an EFFICIENCY of from 55 to 65%. This efficiency is the ratio of h absorbed per pound of dry coal by the water and steam in the boiler to the ac heat-value of one pound of the coal, and is the COMBINED EFFICIENCY of boiler and furnace.

les of Combustion for Heating-Boilers. Combustion-rates for varying of grates are given in Table XV:

Table XV. Combustion-Rates

Grate-areas	Coal per square foot per hour, in pounds	Remarks
sq ft or less (small),	5	A variation of 10% up or down from these rates is perfectly safe. The higher values are for full-sized chimneys with lined flues and the lower for unlined flues or long breeching-connections.

ı ft or larger (large),	6.6	
to 8 sq ft	4	(Am. Soc. H. and V. E. Com. 1909.) Rates of combustion reported for anthracite coal, as fired in internally fired heating-boilers. See Transactions for further details.
to 18 sq ft	6	
to 30 sq ft	10	

ıg of Heating-Boilers. Standard Conditions. It is the general cus- American manufacturers of heating-boilers to rate their boilers in terms umber of square feet of standard direct cast-iron radiating-surface which er is capable of supplying under the following conditions:

team boilers; steam-pressure 2-lb gauge at boiler.

'ot-water boilers; water-temperatures: 180° F. leaving, and 160° F. boiler.

uel; anthracite coal of stove-size.

ATE OF COMBUSTION, or amount of coal necessary per hour for the boiler op its rating has, until recently, seldom been given; and the method of ing the rating has varied with different makers and is seldom stated. r, it is possible for a boiler to be placed on the market and assigned a ating although such rating has never been actually checked by test. ore becomes most important to not only establish STANDARD CONDITIONS NG-TESTS, but to require the manufacturer to be in a position to pro- tified test-sheets of such tests for his line of boilers. The STANDARD NS under which a boiler should be tested to develop its rating are gen- derstood by the manufacturers at the present time to be as follows:

essure, temperature and fuel as stated above.

el-capacity to be sufficient to carry the boiler from 6 to 8 hr on one id leave 20% reserve for igniting fresh charge.

aft of sufficient intensity to burn the fuel at the required rate. A not less than 40 ft in height is recommended.

ch square foot of direct cast-iron radiation has a transmission-value of and 150 Btu per hour for steam and water-radiators respectively.

condensation from steam-radiators returns to the boiler at the same ure as the steam, or without loss of heat, so that the boiler simply sup- atent heat of evaporation at 2 lb pressure, or 967 Btu per lb evaporated.

water from hot-water radiators returns to the boiler at 160°, allowing in the radiators, so that there is no loss in temperature allowed in -main.

able heat-allowance must be made for all connecting piping and boiler- ıd such surface must be figured as radiating-surface or its equivalent.

A general rule is to add, for an ordinary installation, about 50% of the sq ft radiation installed, in calculating the total load on the boiler, with anthrac fuel and 65% with bituminous fuel, to allow for radiation-loss of piping and boi and the additional tax on the boiler due to starting up with cold radiation.

Equivalent Boiler Horse-Power Rating of Heating-Boilers. T capacities of heating-boilers may be stated in boiler horse-power, and the equiv lent of same in square feet of standard radiation may be easily determined follows:

Since 1 boiler horse-power is equal to 34.5 lb of water evaporated per ho from and at 212° F., the boiler must deliver

$$34.5 \times 971.7 \text{ (latent heat at } 212° \text{ F.)} = 33\,524 \text{ Btu per hr}$$

Now since 1 sq ft of standard cast-iron steam-radiation transmits 250 B per hour,

$$1 \text{ boiler horse-power} = 33\,524/250 = 134.1 \text{ sq ft of this radiation, or}$$

$$1 \text{ sq ft of direct cast-iron steam-radiation} = 0.00756 \text{ boiler horse-power}$$

It also follows that the equivalent boiler horse-power rating of a hot-wa heater is

$$33\,524/150 = 223.5 \text{ sq ft of direct cast-iron hot-water radiation, or}$$

$$1 \text{ sq ft of direct cast-iron hot-water radiation} = 0.00447 \text{ boiler horse-powe}$$

Grate-Surface. It is always advisable to check THE GRATE-AREA REQUI for heating-boilers, especially if the total heat-loss to be supplied by the bo is known. This total heat-loss must include not only the calculated loss, d to transmission through walls and glass, for which the radiation is proportion but also about 50% additional for heat-losses from the piping system, boi etc. So that, if H is the building-loss in Btu, $1.5\,H$ = total Btu-loss.

Then

$$G = 1.5H/(C \times F \times E)$$

where C = rate of combustion in pounds of dry coal per square foot of gra area per hour, F = calorific value of fuel in Btu per pound of dry coal (12 0 is the usual assumption for anthracite coal), and E = the combined efficiency boiler and grate (60% is the usual assumption). G is in sq ft and the boi selected should have not less than this grate-area. Special attention is cal to the distinction between GRATE-AREA and FIRE-BOX or FUEL-POT AREA explained below under Depth of Fuel-Pot.

Depth of Fuel-Pot. The average of the fire-box area is usually somew larger than the grate-area in sectional boilers, while it may be less than grate-area in certain types of round boilers. In any event the capacity of fire-box or fuel-pot from grate to middle of fire-door should always be s ficient to hold all the coal required for an 8-hr firing-period, plus at least a reserve to be used for igniting a fresh charge.

The following method is used to determine the depth of pot or the firing-pe as the case may be. Let G = grate-area in sq ft, C = rate of combustion, A average area of fire-pot, h = firing-period in hours, W = weight of fuel per c (50 lb for anthracite and 40 lb for bituminous), D = depth of fuel-bed in Then $(GC\,h)$ + 20% (allowance to ignite fresh charge) = total weight of charge; also, AWD = total weight of one charge. Hence

$$D = 1.2GCh/AW, \text{ or } h = AWD/1.2GC$$

oted above D is measured from grate to center of fire-door, which varies 3 × 14 in in small, to 11 × 19 in in large boilers. This formula allows greater bulk of soft coal.

ple. Given a boiler with grate-area of 8 sq ft, average area fire-pot height to center of fire-door = 18 in, rate of combustion = 6 lb per sq ft e for anthracite coal. Required the number of hours this boiler will ts load on one charging.

ion.

$$h = (9 \times 50 \times 1.5)/(1.2 \times 8 \times 6) = 11.7 \text{ hours}$$

ts of Fuels on Ratings. All ratings are based on ANTHRACITE COAL OF SIZE unless otherwise stated. In case bituminous coal is used and the s selected by catalogue-rating, a boiler with fire-pot having at least 25% capacity should be selected, for the same weight of coal occupies 25% ace. With SOFT COAL additional heating-surface is also required as the lation of soot from such coal renders the heating-surfaces less effective hen hard coal is used. Boilers for PEA-COAL should also have a larger than those for stove or furnace-coal. The SMALL SIZES OF ANTHRACITE far more ash than the larger sizes, and hence have a greater bulk for the ating effect; so that larger fuel-pots for the same capacity are required. PERIODS, differing from the one on which the boiler is rated, will also affect holding capacity. For example, if it is required to operate a certain line s designed for an 8-hr period on a 12-hr basis, at least 50% greater fuel-capacity will be necessary and a larger boiler must be selected, as shown ormula already given for the depth of the fuel-pot.

alent Rating for Conditions Other than Standard. If often happens load connected to a steam-or hot-water boiler may not be operated under dard conditions previously assumed as a basis of rating. In this case ratings cannot be used until the EQUIVALENT VALUE of this load in square feet of standard cast-iron radiation has been determined. llowing relations show a method for finding such equivalent values: = sq ft standard cast-iron radiation = 250 Btu per sq ft for steam, and per sq ft for water. Also let

r = actual sq ft of radiation to be supplied;
K = coefficient of transmission for this radiation;
or t_w = temperature of steam or average temperature of hot water in the radiator;
t_a = temperature of air surrounding radiator;
$t_a)$ = radiation-factor or Btu given off per sq ft per hr;

$$R_s = r_1 \times K_1(t_s - t_a)/250, \text{ and } R_w = r_2 \times K_2(t_w - t_a)/150$$

e. (Steam-heating.) Required the size of boiler (rating in sq ft of cast-iron radiation) to supply 1 000 sq ft of direct pipe-coil radiation. essure = 5-lb gauge. Air = 65° F. K (by test) = 2.42 Btu. From les, t_s = 227.14, R = 1 000 × 2.42(227.14 − 65)/250 = 1 000 × 52.14)/250 = 1 570 sq ft. To this add 50% for pipe and boiler- and the additional tax for starting up with cold radiation, or, 1.5 × 355 sq ft, or practically a 2 400-sq-ft-capacity boiler will be required. should be checked by calculation previously given to ascertain size.

$$G = 1.5H/(C \times F \times E)$$

Example. (Water-heating.) Let Q = total number of gal of water to l heated in h hours.

$$W = (8\tfrac{1}{3} \times Q)/h = \text{weight of water to be heated per hour}$$

$$t_1 = \text{initial temperature of water, } t_2 = \text{ final temperature of water}$$

Then $W(t_2 - t_1)$ = Btu to be supplied per hour. Hence $W(t_2 - t_1)/150$ = ho water-heater rating required. $W(t_2 - t_1)/250$ = steam-boiler rating require

Example. A swimming pool contains 50 000 gal of water, and this water heated by being passed through a hot-water heater in four hours. Enterin temperature = 50° F. and final temperature = 75° F. Hot-water radiati reduced to equivalent standard value = $[(50\,000 \times 8\tfrac{1}{3})/(4 \times 150)]$ $(75 - 50)$ = 17 350 sq ft = rating of hot-water heater, to which must be add 50% for losses from piping, etc.

Fuel-Consumption. The ESTIMATED FUEL-CONSUMPTION FOR HEATIN BOILERS per heating-season may be based on grate-areas, square feet of radiati installed, or cubic contents of building to be heated. The United States Treasu Department allows 5 tons of coal per sq ft of grate-area per season of 240 day or 1 lb of coal per cu ft of contents of building for the same period. Th applies to government buildings. The district steam-heating companies estima 500 lb of steam per sq ft of direct steam-radiation per season, which is practical the same as 70 lb of coal of good quality. This is approximately equivalent assuming that one-third of the radiation installed is in operation continuously f 240 days. In other words, the coal required for a heating-season is about on third the quantity that would be used if all the radiation were in constant u every hour of the day and night. The amount of coal for maximum conditio is determined as follows:

Since each foot of direct steam-radiation or its equivalent will give off 2 Btu per hour under conditions of 2 lb (220°) pressure at boiler, and 70° air su rounding the direct radiators (the piping on the average job may be rough taken as 25% of the direct radiation); and since for approximation we m assume 8 000 Btu per pound of anthracite coal burned; we can readily estima the amount of coal per hour if R = amount of direct radiation in square fe

$$(1.25 \times R \times 2.50)/8\,000 = C = \text{coal per hour in pounds}$$

In a heating-season of 7 months or 210 days of 24 hours each, there would burned under maximum conditions during the entire period

$$(1.25 \times R \times 250 \times 210 \times 24)/(8\,000 \times 2\,000) = 0.0984R \text{ tons of coal}$$

the actual consumption being about one-third of the maximum possible, 0.0328 R tons of coal for the heating-season. For hot-water heating the fu consumption for the entire season is approximately 0.0197 R tons.

Types of Heating-Boilers. Cast-iron steam-heating boilers are designed be operated at a maximum pressure of 15 lb per sq in, and the sections are test by the manufacturer to about 100 lb per sq in, hydrostatic pressure. Cast-ir boilers are constructed of sections, which are connected by means of nipples either the push or screw-type. The sections are held in place by means of lo bolts. Round-type boilers have horizontal sections surrounding the fire-p and in the sectional type the sections are placed vertically. (See Figs. 16, 1 and 18.) The maximum size of round-type boilers manufactured is rated about 1 400 ft. Sectional boilers are obtainable up to a 10 000-sq-ft-rati See manufacturers' catalogues for capacities, dimensions, etc.)

ikeless or Down-Draft Cast-Iron Boilers. Boilers having a water-grate w being made for use with free-burning soft coal, where local smoke-nces would not permit the use of such fuel on ordinary grates.

Fig. 16. Sectional Type of Cast-Iron Boiler

17. Trimmings and Connections for Sectional Steam-heating-boiler

Selection of Cast-Iron Boilers. The selection of cast-iron boilers sho not be influenced too largely by considerations of price, and the ease w which they may be carried into a building where structural conditions interf with the introduction of a steel boiler. many cases the character of the service attendance, or both, especially in gove ment and other public building work, m be such that steel equipment, which is c able of withstanding more abuse, should used. This is particularly true when t returns are handled by a pump. If ca iron boilers are to be installed, the gra area necessary should be carefully comput as already indicated, using an average ra of combustion, and a fuel-pot depth bas on the firing-period required. The Unit States Treasury Department selects ca iron boilers by proportioning them to ca 25% more radiation than actually instal if anthracite coal is used, and 35% more bituminous coal is used. In addition this, suitable allowance must be made mains and other piping, and in most ca two boilers are installed, each capable supplying two-thirds of the radiation order to provide for units which can operated with a high-load factor, and a act as a reserve for each other in case o breakdown.

Fig. 18. Section of Round-type Boiler

Steel Heating-Boilers. There are two general types of all-steel boilers u for heating work, the FIRE-BOX TYPE and the RETURN TUBULAR TYPE.

In the fire-box type the grate and combustion-chamber are surrounded by extension of the steel shell which is water-jacketted. The products of co bustion pass directly through the tubes to the smoke-flue located in the re In the return tubular type, the boiler consists of a shell with tubes set i brick setting, the grate and combustion-chamber being directly under t front portion of the shell. The products of combustion in this case pass und and around the shell to the rear of the boiler, and then through the tubes the front into the smoke-box.

Fire-box type boilers may be obtained in capacities ranging from 500 to 13 0 sq ft of direct radiation. The most common of these boilers are the Dunni Gorton, and Kewanee. Detailed information as to capacities, dimensions, e may be obtained from the makers' catalogues. As usually constructed, th boilers are designed for a working pressure of 60 lb per sq in and are so insu by the boiler-insurance companies. This type may be obtained with or with (portable type) brick-setting. The return tubular boiler is erected wit brick setting and as ordinarily constructed, is designed for a working press of 100 lb per sq in, but may be obtained for a working pressure of 150 lb per s if desired. It is primarily a power-type boiler, but is commonly used in c junction with large heating systems having 10 000 sq ft or more of direct ra tion. These boilers are rated on a basis of 10 sq ft of boiler heating-surface boiler horse-power. A special design of setting is required for smokeless c bustion when bituminous coal is to be used as fuel The so-called stand setting should not be used in this connection. (See Boilers and Rules for C

ion in Mechanical Equipment of Buildings, Vol. II, by Harding and d.)

mneys for Heating-Boilers. (See also, under Chimneys, page 1364.) er to produce an intensity of draft sufficient to properly operate low-e heating-boilers, hot-water boilers, and hot-air furnaces up to their apacity, the chimney should not be less than 40 ft in height, measured ie grate. No flue should be less than 8 × 8 in. The failure of many -installations may be traced to insufficient draft to burn the fuel at the quired to run the boiler or furnace to rated capacity. The tempera-flue-gases leaving the boiler should range between 400° and 500° F. when paratus is worked at its rated capacity. The chimney should be so with reference to any higher buildings nearby that wind-currents will n eddies and force the air downward in the shaft, as shown in Fig. 19. ie should run as nearly as possible from the base top outlet. The outlet ot be capped so that its less than the area of the he flue should have no into it other than the moke-pipe. Sharp bends ets in the flue often reduce and choke the draft, and must be free of any which prevents the full the passage of smoke. If the flue is made of tile, the joints must be iented, or all space between the tile and brickwork filled in tightly. ust be no open crevices into the flue where the tile sections meet, other- draft will be checked. If the flue is made of brick, the stack should side walls at least 8 in thick to insure safety. The inside joints should truck, and each course should be well bedded and free from surplus t the joints. The exposed bricks at the top of a brick chimney should

be laid in cement mortar to prevent the acid fumes and rain from cutting the joints. This will happen if lime mortar is used. The most desirable lo tion for a chimney is near the center of the building, as all walls are then k warm. If there is a soot-pocket in the flue below the smoke-pipe opening, clean-out door should always be tightly closed. If this soot-pocket has ot openings into it from fireplaces or other connections, these openings check draft and prevent the best results. The smoke-pipe should not extend into flue beyond the inside surface of the latter. If it does extend beyond, its cuts down the area of the flue. The joints, where the smoke-pipe fits smoke-hood of the boiler, or where the pipe enters the chimney, should be m tight with boiler-putty or asbestos cement. Fire-clay flue-linings are used the best practice for small and medium-sized flues. Rectangular flue-lini are rated by outside dimensions, and round linings by inside dimensions.

Flues for Kitchen Ranges and Fireplaces. (See also, under Chimn page 1364.) For a kitchen range an 8½ by 8½-in tile flue is ordinarily suffici but an 8½ by 13-in is better. For fireplaces the sectional area of the flue burning wood or bituminous coal should be from 1/10 to 1/8 the area of the f place-opening for a rectangular flue, and 1/12 for a circular flue. For burn anthracite coal the areas may be reduced to 1/12 and 1/16 respectively.

Selection of Chimney-Flues. (See also, under Chimneys, page 1364.) T selection of chimney-flues for heating-boilers must depend upon the judgmen the heating-engineer, but it is believed that Table XVII, by R. C. Carpenter, very much assist the engineer in selecting flues. It is necessary that AREA HEIGHT, THICKNESS OF WALLS, GENERAL STRUCTURE, and the POSITION OF TOP OUTLET with reference to the building and other buildings near by should carefully noted and observed in the selecting or building of a flue. The fig given under the varying heights of chimneys are diameter-measurement inches, or, the side of a square, the theory being that the spirally ascen column of smoke and gases will make a 12 by 12-in flue no more effectiv practical working-area than a twelve-inch round flue. Rectangular shapes be used if the area is equal and the difference in width and breadth is extreme. A maximum ratio of 2 : 1 for the internal dimensions should not exceeded.

Table XVII. Chimneys for Steam and Hot-Water Boilers

te-Areas and Stack-Dimensions. For return tubular S. Thompson gives the following rules for grate-areas and

. radiation in building; B. H. S. = heating-surface in boiler; ; (all in sq ft)

7 for steam; R ÷ 11 for water. G = B. H. S. ÷ 25 (anthra-oal); G = B. H. S. ÷ 30 to B. H. S. ÷ 35 (bituminous coal, B. H. S. ÷ 45 (lower grate of down-draft furnace).

tack, ft. A = area of grate, sq ft. S = area of stack, sq ft.

(anthracite coal, lump coal, oil, and gas).

) + $\sqrt{H}$ (bituminous and small anthracite).

pea, or rice coal, tube-area must be not less than ⅛ grate, and n stack.

h down-draft furnace, tube-area must be not less than ⅙ of always larger than stack.

th of tube must not exceed 48 diameters.

gth of boilers, 54-in diameter and under, must not exceed 3 54-in, 2½ diameters.

number of feet in length, are not used.

ll Buildings are special cases and may be designed by methods ign of chimneys for power-boilers. (See Power Plants and r Harding and Willard. See also, List of Tall Brick Chimneys,

Direct Steam Heating

Direct Steam Heating in Use. Systems for heating with direct are broadly divided into two general classes, known as: (1) LATING SYSTEMS, and (2) MECHANICAL CIRCULATING SYSTEMS. ing characteristic is the manner in which the water of condensa-diators is returned to the boiler. In the first type the condensate er by gravity, due entirely to the STATIC HEAD existing in the e sytem is a closed circuit. The steam-pressure existing in the and radiators is the same, except for friction-pressure losses due team to the heating-surfaces. In the second type the condensate turn to a receiver or feed-water heater and is then forced into the MP, or RETURN-TRAPS, or both. This is not a closed system, and . the boiler may be much higher than that in the mains and radi-ceiver is usually vented to the atmosphere, and in the case of ns an additional pump is attached directly to the returns and scharge the condensation into the receiver or heater. Gravity cir-ns are further divided into the ONE-PIPE SYSTEM and the TWO-PIPE basement-mains supplying risers to the various floors above (Figs.), or with overhead mains supplying drop-risers to the floors below. system the steam and water of condensation in the risers flow in ction, so that less friction is produced as countercurrents do not aller pipe-sizes may be used. The overhead system is very com-n of as the MILL'S SYSTEM.

Gravity Systems. The ONE-PIPE CIRCUIT SYSTEM (Fig. 20) with ins is probably the simplest, and most common gravity system in eam-main rises close to the basement-ceiling, just above the boiler, des down uniformly from this high point with a fall of 1 or ¼ in in n the last radiator has been served the main drops below the boiler

water-line and its size is reduced, as on the run back to the boiler it carries on condensation and is known as a WET RETURN. This return may be run above the boiler water-line if necessary, and is then called a DRY RETURN. Return-mai are graded 1 in in 30 ft in gravity work. In either case an automatic air-val

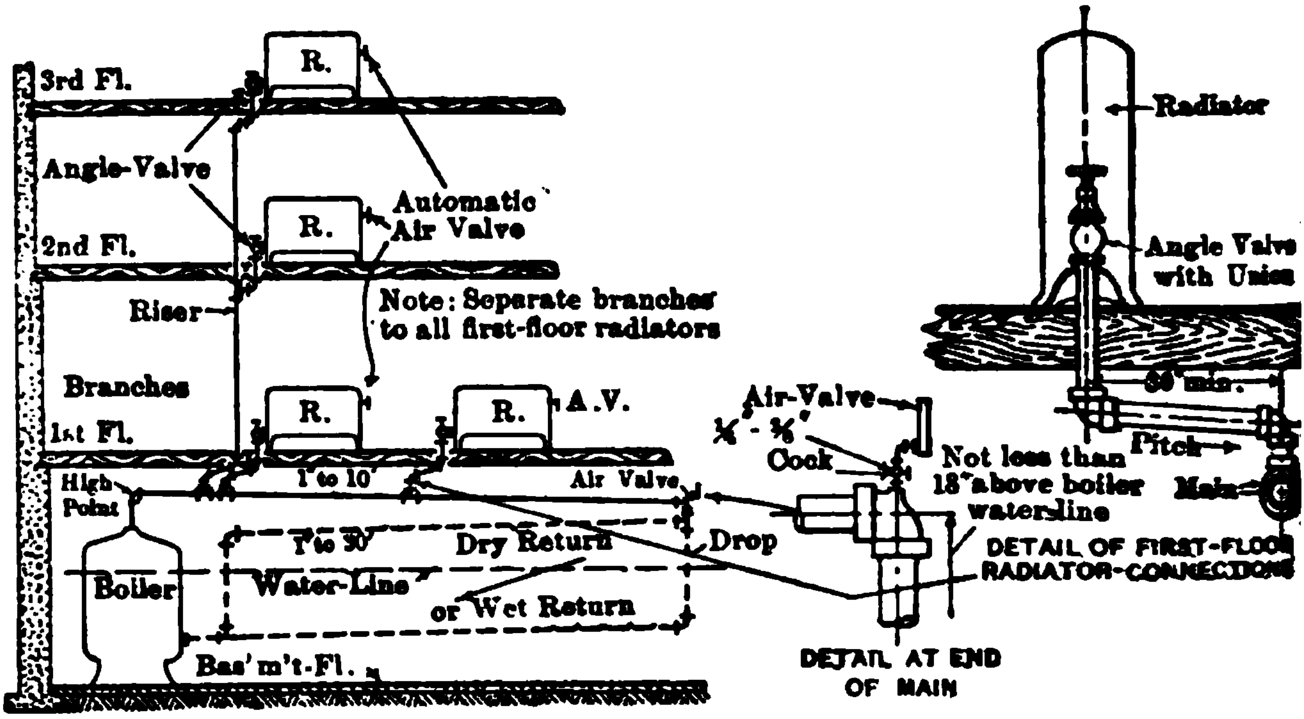

Fig. 20. Low-pressure Gravity System. One-pipe Basement-main

must be installed on the end of the main at the drop, as shown, to vent the sa when air collects in the piping. The elevation of the end of the steam-main wi respect to the boiler water-line must be carefully determined, in order that wa may not back up from the boiler and flood the main, including the air-valve a

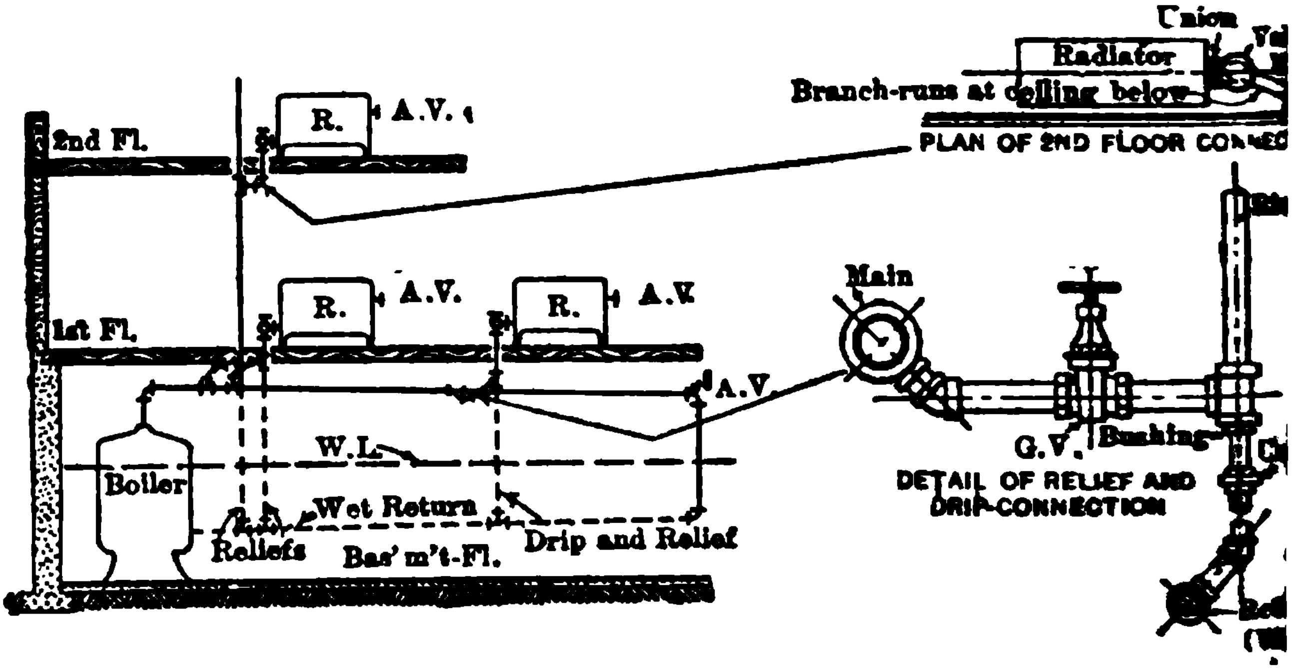

Fig. 21. One-pipe Relief Basement-main

branches. It is customary to maintain at least 18 in between the under sid main at the drop and the normal water-line of the boiler to provide for con gencies. In operation it will be noted that steam and water flow in the s direction through the one-pipe steam-main, and in opposite directions thr the basement-branches, risers, and radiator-branches. This necessitates la piping and valves than in any other steam system, and especially is this t of the main, which must be run full size from boiler to drop, unless dripped shown under piping-details.

ᴜᴍᴘ ꜱʏꜱᴛᴇᴍ (Fig. 21) is very similar to the one-pipe circuit . the risers are dripped individually into the return, and the no radiator-condensation, and is itself dripped at intervals in, which may run ᴅʀʏ or ᴡᴇᴛ. This makes it possible (1) f main as radiation is taken off, (2) to use smaller branches, main much closer to the basement-ceiling, a very important e basement-space is valuable. A ᴄᴏᴍʙɪɴᴀᴛɪᴏɴ ᴏꜰ ᴛʜᴇ ᴏɴᴇ- ᴇ ᴛᴡᴏ-ᴘɪᴘᴇ ꜱʏꜱᴛᴇᴍ is frequently used in large installations, ed for the first and second floors, and the former for the buildings. In this way the amount of condensation flowing risers against the steam is much reduced and smaller risers application of the one-pipe system, with gravity-circulation ts to tall buildings, is not at all unusual, and if the piping is or the circulation of steam and the return of the water of be found satisfactory. In the case of long narrow buildings system it may be necessary to provide a deep boiler-pit so f water in the return-connections will not flood the far end

y Systems. The ᴛᴡᴏ-ᴘɪᴘᴇ ꜱʏꜱᴛᴇᴍ with basement-mains sed in large buildings, and in ᴀʟʟ ᴡᴏʀᴋ ᴡʜᴇʀᴇ ɪɴᴅɪʀᴇᴄᴛ

ʟᴇᴅ. This system can be readily adapted to mechanical d is very extensively used in this connection. It will be t when applied to a gravity system the return from each ʟʏ ꜱᴇᴀʟᴇᴅ, either by dropping below the water-line to a using drip-loops, as shown at the left, before connecting to in one-pipe work all drips or reliefs are sealed as shown in aution is not taken steam may enter a drip or return from use knocking in the system due to countercurrents of steam ation. Any drip, relief, return-riser, or connection from the ide of the system ᴍᴜꜱᴛ ʙᴇ ꜱᴇᴀʟᴇᴅ. This may be done by water-line, or else by using a running trap or a return-trap onnecting line. Neglect of this precaution will cause an ion of the system.

tor Air-Valves for Gravity Systems. The ᴀᴜᴛᴏᴍᴀᴛɪᴄ ı steam-radiators must be provided for if the highest effi- g-surfaces is to be realized in gravity circulating systems.

Manually controlled air-valves or cocks are usually neglected, and are seldo used for steam-radiators although their use is quite general for hot-water ra ators. Fig. 23 shows a float-type of automatic air-valve. Thermostatic a valves are finding favor in this field. The proper LOCATION OF THE AIR-VAL on a steam-radiator is at the end of the radiator opposite the steam-inlet, and near the bottom of the radiator as possible, since air is heavier than steam the same temperature. In practice, however, the manufacturer of radiato

VALVE CLOSED VALVE OPEN

Fig. 23. Norwall Automatic Air-valve

usually places the air-valve tapping about two-thirds the height of the radiat from the floor in order to prevent possible flooding of the valve.

Special Gravity Systems. In addition to the low-pressure gravity syste already described there are many special steam heating systems known as AI

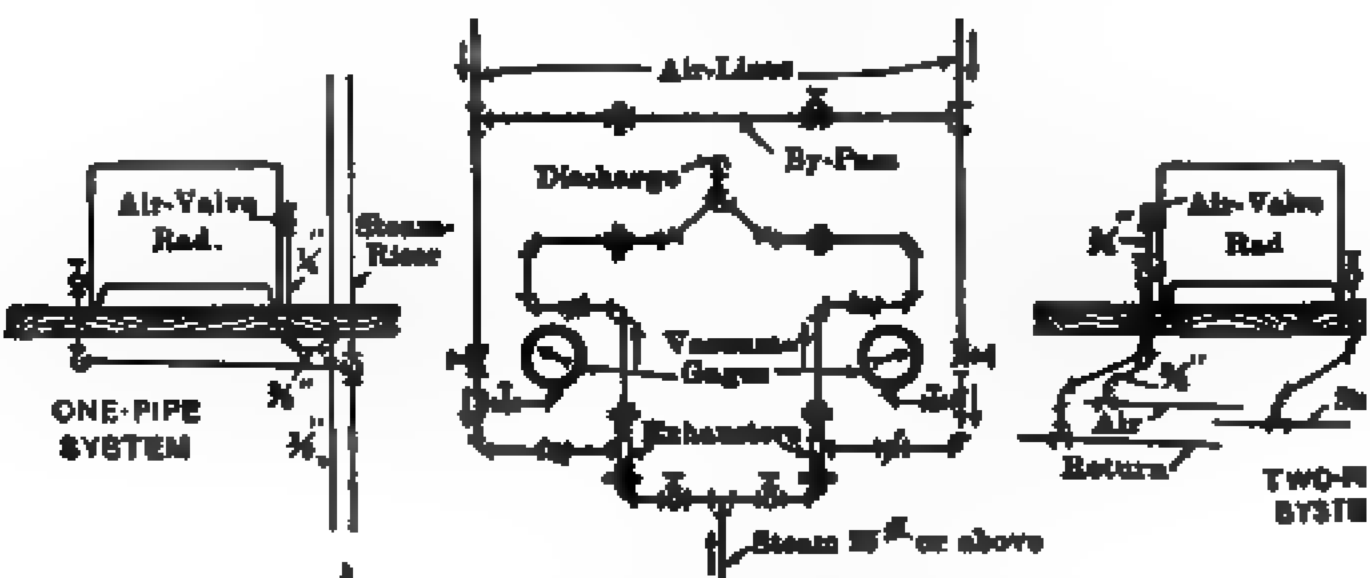

Fig. 24. The Paul Air-line System

LINE, VAPOR, and VACUUM SYSTEMS, also operating with gravity-return of t water of condensation. The AIR-LINE SYSTEM may be attached to any one two-pipe gravity system, and is applied by connecting the automatic air-val of each radiator with small-size piping to an exhauster which maintains a slig vacuum in the air-piping and effectually removes the accumulation of air the radiators. As this scheme is a positive means of air-removal its applicati to the ordinary one or two-pipe gravity system will improve its operati The original air-line system is known as the PAUL SYSTEM (Fig. 24). The e hauster used for less than 2500 sq ft is a water-driven vacuum-pump, with a pr

i at least 20 lb per sq in. Larger systems use a high-pressure steam-jet bove), or if steam is not available, a motor-driven vacuum pump of about se-power, 1 in air-mains in basement, and a gate valve on each air-riser ed. The steam used varies from 1 to 5% of the total condensation. All or-connections are made as shown. The Bishop-Babcock-Becker Com-

trap, usually of the thermostatic type and commonly termed a VACUUM-VALVE, such as the Dunham (Table XX), Webster, Illinois, Monash, etc. A volatile liquid is employed in the thermostatic element or bellows. This liquid is vapor-ized immediately as steam is brought in contact with the bellows, and causes the latter to expand and thus close the valve. The temperature of the con-densate from the radiator is slightly below the temperature of the steam but is not sufficiently high to vaporize the liquid. The valve therefore remains open and will pass the water of condensation and air until the steam starts to flow, when it immediately closes. These valves are very sensitive, and when prop-erly adjusted and in order will not blow steam. One type of THERMOSTATIC VALVE is shown in Fig. 26. It is cus-tomary practice to connect a ½-in cold-water line to the main return at the pump, which serves to condense any steam that may leak by the vacuum-

B.T.	1	3 000	1	21	1	....

These traps are designed for steam-pressures not in excess of 10-lb gauge. For ma and riser-drips, use no smaller trap than the No. 3, and install trap as per details.

Care must be exercised in selecting a trap or traps of the proper size for hot-bla heating-coils. The capacity-ratings for all traps are in terms of direct cast-iron radi tion, on a condensation-basis of approximately 0.25 lb per sq ft per hr. Every unit blast-coil must be reduced to that basis before trap-sizes are chosen and specified. (S Hot-Blast Heating for further details in reference to rating of vacuum-traps for ho blast coils.)

Size of Vacuum-Pump Required. The following table by the Warn Webster Co. may be used in determining the size of steam-driven vacuum-pun necessary. To determine the size of pump required the following empiric formula is used:

Square feet of direct radiation + (number of units × 100) = F. Choo the nearest size corresponding to the value of F given in the table. The stea cylinders are proportioned on a basis of 80-lb pressure and for lower pressur the steam-cylinder must be proportioned accordingly.

Example. Required the size of pump for 5 000 sq ft of direct radiation in 15 radiators. 5-000 + (150 × 100) = 20 000. Use a 5 × 6 × 10-in pump.

This table may also be employed in determining the size of motor-drive reciprocating vacuum-pumps, the last two figures under Size being the diamete

roke, respectively, of the pump. A vacuum-pump should be specified to
ı displacement of at least from 10 to 15 times the volume of the con-
e when operating at its normal rated speed.

Table XXII. Capacity and Size of Steam-Driven Vacuum-Pumps

densation figured at 0.3 lb per sq ft radiating-surface per hour.

ım-pumps with belted electric motors are made by the Bishop-Babcock-
Co., with capacities of 2 000, 5 000, 10 000, 17 000 and 25 000 sq ft of direct
ı. This pump should be under the control of a reliable VACUUM-PUMP GOVERNOR
rhen the required vacuum has been produced the pump will stop.

Design of Low-Pressure Steam-Heating Systems

ınt of Radiation Required. The heat-loss, H, of the various rooms is
ed as previously indicated, and H is divided by 250. The result is the
of direct radiation in square feet required. The heat-emission of cast-
iation for pressures up to 5 lb per sq in may be assumed as 250 Btu for
ical purposes of calculation.

g of Boiler Required. If anthracite coal is to be used for fuel add not
ı 50% to the total amount of direct radiation to be installed and 65%
inous coal is to be used, to allow for radiation-loss of boiler, mains,
etc. The steam-mains and risers should always be covered.

of Mains, Branches and Return-Pipes. Steam-mains in low-pressure
systems should be so proportioned that the loss in pressure, due to pipe-
does not exceed approximately 1 oz or 0.062 lb per sq in, per 100 ft of
e reason for thus limiting the pressure-loss is apparent from an inspec-
ig. 31. Owing to the fact that the steam is losing pressure as it flows
the main, it follows that the pressure at the last riser will be lower than
oiler. The difference in pressure, or pressure-loss, P, causes the water
eturn-main to stand higher than the water-line of the boiler. The
ight Z is equal to the height of a column of water which pressure P
ort. Thus, if the boiler-pressure is 2 lb per sq in and the pressure at
ıd of the main is, say 1½ lb, with water weighing 61 lb per cu ft, or 0.035
in, the water in the return will stand $(2 - 1.50) \div 0.035$, or $Z = 14$ in
water-line of the boiler for a ½-lb loss in pressure between the boiler
end of main. It is apparent in this instance that unless the water-line

of the boiler is about 18 in or more below the last riser, or radiator-connecti water is quite likely to flood the steam-main and to be accompanied by a ha mering and a poor circulation in the radiators located at or near the end of t run. Steam-mains are graded in the direction of flow approximately 1 in in 10

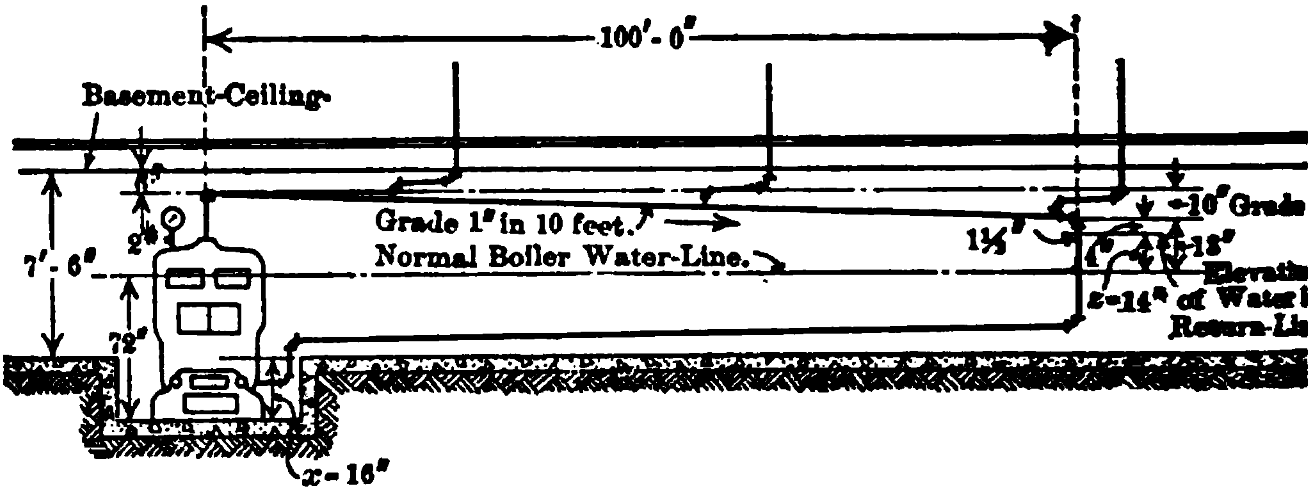

Fig. 31. Location of Boiler and Arrangement of Pipes for Low-pressure Steam-heati Systems

Referring to Fig. 31, and assuming a 7 ft–6 in, or 90 in, clear height of bas ment, and a boiler having a 72-in water-line and a length of steam-main of 100 it is evident that the boiler must be located in a pit, the depth, X, of which

$$6 + 10 + 18 + 72 - 90 = 16 \text{ in}$$

in order to maintain 18 in between the water-line in the boiler and the end steam-main. The distance in practice should not be made less than from to 24 in. The extreme pressure-load stated, ½ lb, in this illustration, is nev approached in normal operation, when the mains are designed for 1-oz dro per 100 ft, but may approach the value stated when the system is being starte up with cold radiators, when the rate of condensation is very much higher. Th pressure-loss in a pipe flowing full of steam may be approximated b Babcock's formula

$$W = 87.5 \sqrt{\frac{ypd^5}{L \times \left(1 + \frac{3.6}{d}\right)}}$$

in which W is the weight of steam flowing per minute in pounds, L the length o pipe in feet, d the diameter of pipe in inches, y the density of the steam and the loss in pressure in pounds per square inch.

One square foot of direct radiation will condense, under normal conditions o operation, 0.25 lb per hr, and the density of steam, y, is 0.043 lb for a 2.3-l pressure. The sizes of steam-mains given in the tables were calculated by th above formula, the pressure-loss, p, being limited to 1 oz, or 0.062 lb per sq i per 100 ft of straight pipe. To allow for the fittings approximately twice thi or ⅛ lb per sq in per 100 ft of pipe may be assumed. The pipe-sizes for the one pipe system are given in Table XXIII, corresponding to the amounts of direc radiation stated in the last column. Branches and risers may be taken fro Table XXIV, and reliefs for risers from Table XXV. For the two-pipe and als the one-pipe relief system the steam-main may be reduced in size as rapidly a the radiation carried will permit. The steam-main should not, however, b of any smaller size than risers called for in Table XXIV.

For one-pipe circuit systems, unless the steam-main is frequently dripped

THE MAIN MUST BE RUN FULL SIZE to the end, at which point an automatic air-valve should be installed and the main dripped into the return. This system is generally used for the heating of residences not exceeding two stories in height. For buildings two stories or more in height the one-pipe relief system

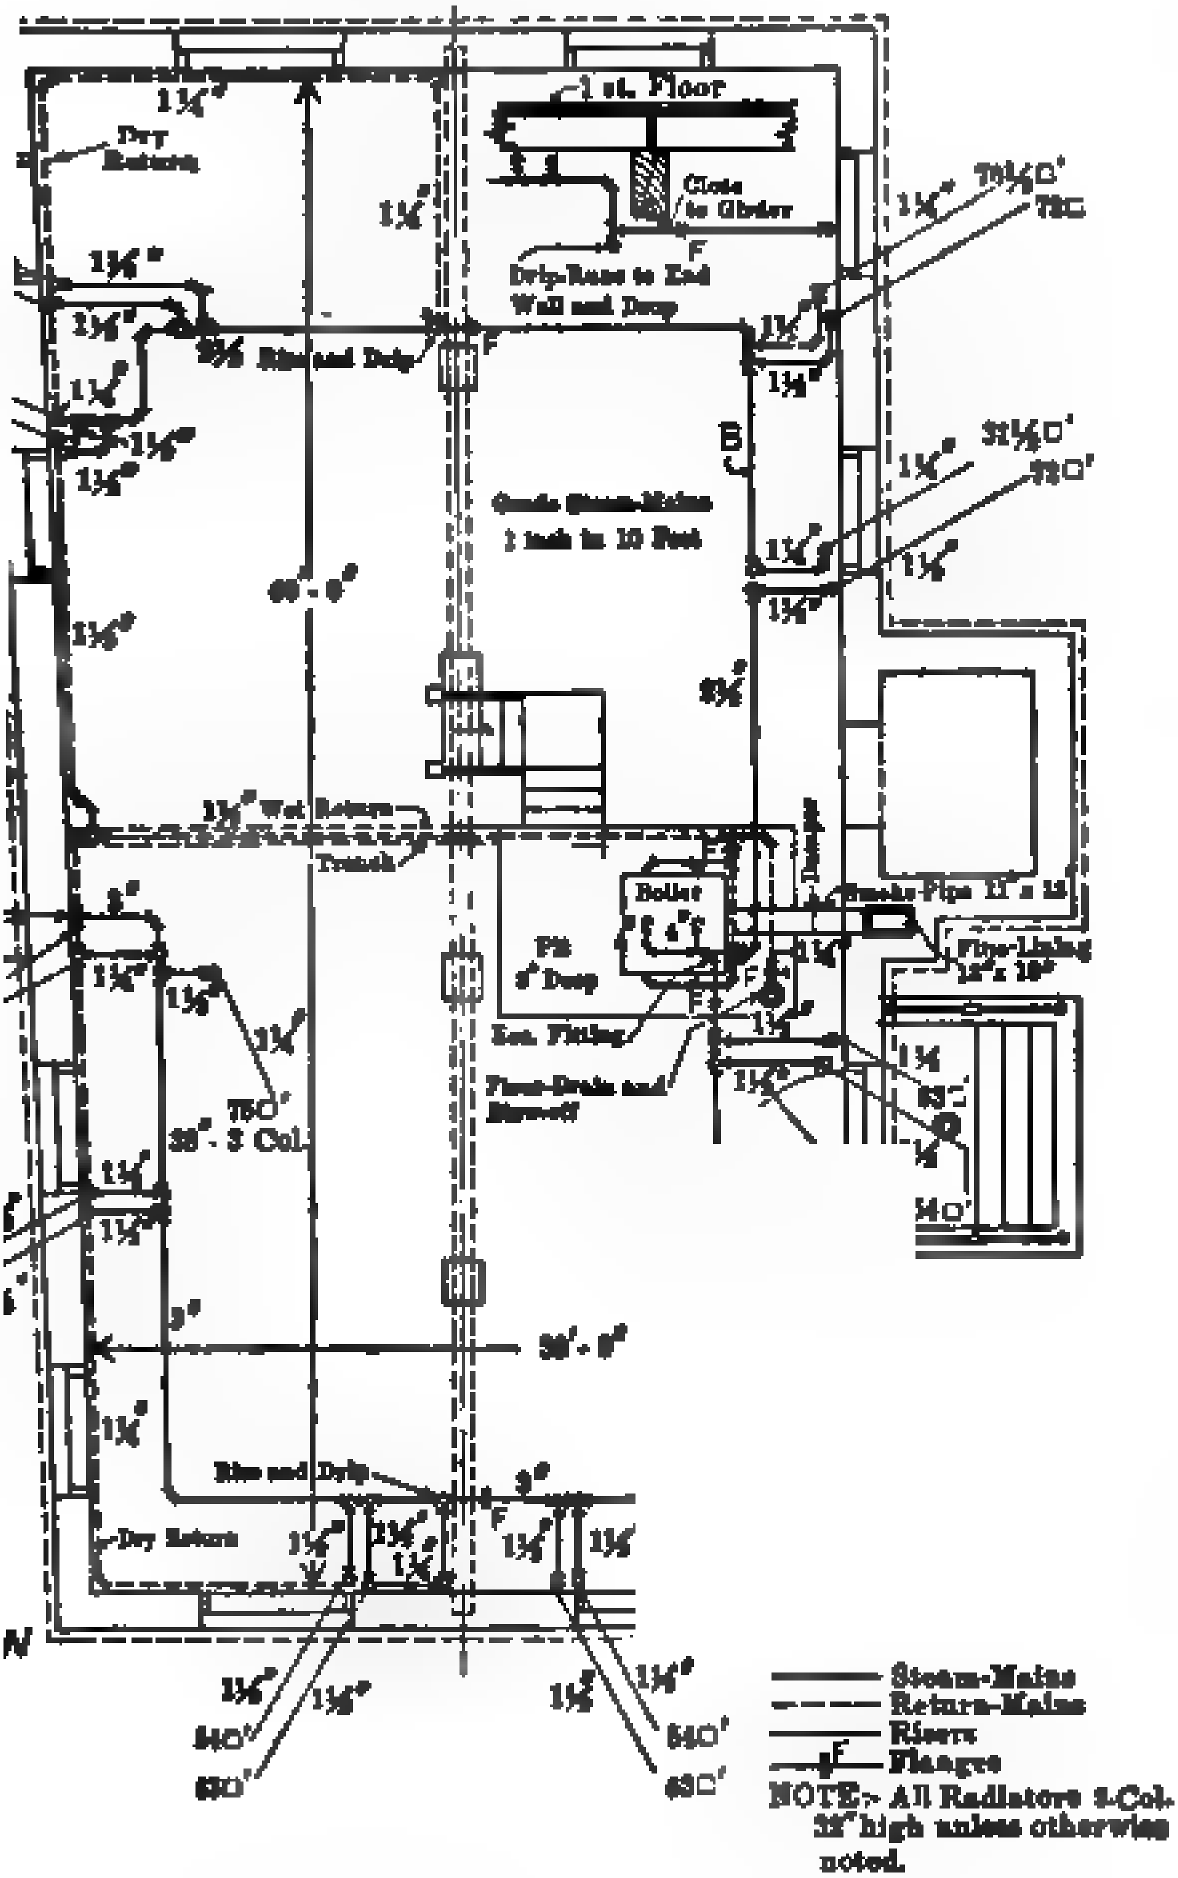
'or Indirect Gravity Radiation. Multiply square feet of a by 2 and use Table XXVI.

)ne-Pipe Low-Pressure Gravity Heating System. Direct t it be required to design a heating system of this type



ıngle-pipe Low-pressure Steam-heating System for Factory Office-building. (See, also, Fig. 9.)

tory office-building shown in Figs. 9 and 34, the heat-losses being as calculated and given by Table VII. The location of the radiators cated on the floor-plans, Fig. 9.

Direct Radiation Required. The total Btu-loss for each room is repeat in column 2 of Table XXVIII. The amounts of radiation required for these los is given in column 3 and were obtained by dividing the Btu-loss in each case b 250, the average heat-emission of direct radiation (Btu) per square foot p hour for a room-temperature of 70° and 2 lb steam-pressure.

Boiler-Capacity Required. The boiler-capacity must be such that it wi carry the radiation installed plus the extra heat-loss from the steam-mai return-mains and boiler. The steam-mains are to be covered and anthraci fuel is to be used. The fuel-capacity of the fire-pot is to be sufficient for an hr firing-period. Adding 50% to the sq ft of radiation installed, 1.5×1.1 = 1 662 sq ft, the boiler-rating required. The fuel-holding capacity of th fire-pot should be checked for the boiler proposed as previously stated und Boilers.

Chimney-Size. The size of chimney may be taken from Table XVII, an in this case, is 12×12-in inside dimensions, by a 40-ft height. The neare size for flue-lining, Table XVI, is 13×18 in.

Design of Piping System. The layout of the basement-mains and rise for a ONE-PIPE CIRCUIT SYSTEM is given in Fig. 34. The risers are not drippe in this case. Steam-main *A* supplies 623 sq ft of radiation, and, according t Table XXIII must be 3 in in diameter. The diameter must be carried to th end where it is dipped into the return-main by a 1½-in relief, as indicated i Table XXIII, for a dry return-pipe. In order to keep the steam-main as clo to basement-ceiling as possible, where it passes beneath the floor-girder, a ri is made, and consequently a 1¼-in drip must be provided to take care of 2 sq ft of radiation. The main wet return takes care of 1108 sq ft of radiatio and is therefore made 2-in diameter. The risers and branches are proportione by Table XXIV.

Gravity Indirect Heating

General Description. A satisfactory means of providing for the heat-lo in a room, and, at the same time, supplying air-ventilation, is accomplished b this system. The radiators properly encased with a sheet-metal casing, cov

Spacing of sections, 4 in on centers for gravity air-circulation.

Weight of Air to be Circulated per Minute. W. t_1 = temperature of leaving register. t = temperature of room. 0.24 = sp heat of air. H = he loss of room to be warmed in Btu per hour. V = volume of air in cubic f per minute measured at 70°.

Then $$W = H/[60 \times 0.24(t_1 - t)], \text{ lb of air per min}$$
$$V = W/(0.075 = \text{the density of the air at } 70°)$$

ea of Indirect Heating-Surface Required, S. t_0 = initial temperature of ıtering indirect heater. t_2 = final temperature air leaving heater = $t_1 + 5°$ med temperature-loss in hot-air duct). V = velocity through free area of r in feet per minute, measured at a temperature of 70°. F = total fire-equired in heater, in square feet. a = free area for one section of heater ıare feet. n = number of sections required.

$$F = V/v = W/0.75v, \; n = F/a \text{ and } S = n \times s$$

mple. Required the amount of indirect low-pressure steam-surface of ıtended-surface type, the number and size of sections, and the over-all sions of an indirect radiator to supply the necessary heat to warm a oor room, the heat-loss of which is H = 20 000 Btu per hour. All the air e taken from the outside, the temperature of which is $t_0 = 0°$ F. The temperature to be maintained is $t = 70°$ F.

tion. It is first necessary to assume a temperature, t_1, for the air entering om, in order to calculate the amount or weight, W, of air required to be ted to convey the heat required to make up the heat-loss H.
ıme $t_1 = 95°$ and $t_2 = t_1 + 5$ (loss) = 100°; and v = 100 ft per min. 'able XXIX.

$$W = 20\,000/[60 \times 0.24(100 - 70)] = 46.3 \text{ lb per min}$$
$$V = 46.3/0.75 = 617 \text{ cu ft per min, measured at } 70° \text{ F.}$$

me 40 in as the length of section desired in this installation,

a = 0.35 (Table XXX);
F = 617/100 = 6.17, the total square feet of free area required;
n = 617/0.35 = 18, the number of sections of 40 in.

o is, therefore, required, giving a total heating-surface of

$$S = 10.75 \times 18 = 193.5 \text{ sq ft}$$

g this equally between two indirect radiators the width of each heater to nine (sections) × 4 (spacing-sections) = 36 in.

Pressure Boiler-Rating Required for Gravity Indirect Radiation. ount of heat given up to the radiator is

$$h = 0.24W(t_2 - t_0) \times 60 \text{ Btu per hr}$$

equivalent rating in square feet of direct radiation is therefore R = lus 25% for radiation of mains, returns, etc.

ple. Required the equivalent low-pressure boiler-rating to supply the radiation in preceding example.

on.

$$h = 0.24 \times 46.3\,(100 - 0) \times 60 = 66\,672 \text{ Btu per hr}$$
$$R = (66\,672/250) \times 1.5 = 399 \text{ sq ft}$$

ıer words, 1 sq ft of low-pressure steam indirect radiator with gravity-on is practically equivalent to 2 sq ft of direct radiation; or the amount ct surface is approximately 0.4 of the amount of direct radiation

of Hot-Air Ducts for Gravity-Circulation. A velocity of approxi-ne third of the theoretical velocity attainable by natural draft, due to

the smaller density of the heated air, is assumed in practice in proporti the area of the hot-air ducts.

Table XXXI. Theoretical Velocity (V) of Air, in Feet per Second, Due to Natu Draft

Height of flue in feet, E	Excess of temperature in flue above external air							
	10°	15°	20°	25°	30°	50°	100°	150°
1	1.1	1.4	1.6	1.8	2.0	2.5	3.6	4.4
5	2.5	3.1	3.6	4.0	4.5	5.6	8.1	9.9
10	3.6	4.4	5.1	5.7	6.6	8.1	11.4	14.0
15	4.4	5.4	6.3	7.0	7.7	9.9	14.0	17.1
20	5.1	6.3	7.2	8.1	8.8	11.4	16.1	19.8
25	5.7	7.1	8.1	9.0	9.9	12.8	18.0	22.1
30	6.3	7.8	8.8	9.9	10.8	14.0	10.8	24.2
35	6.8	8.4	9.5	10.7	11.7	15.1	22.3	26.1
40	7.3	8.9	10.2	11.4	12.5	16.1	22.8	27.9

Example. Required the size of hot-air duct for each of the indirect radiat in the preceding examples for a first-floor installation, the effective height E bei 5 ft.

Solution. The excess of temperature in the flue above the external air 100 − 0 = 100°. The theoretical velocity in the duct, from Table XXXI, 8.1 × 60 = 486 ft per min. The actual velocity is approximately one third this, or 162 ft per min. The weight of air per minute passing through the flue 23 lb, or

$$23/[0.071(\text{density at } 100°)] = 324 \text{ cu ft}$$

The required area of the flue is therefore

$$324/162 = 2 \text{ sq ft} = 288 \text{ sq in}$$

The gross area of the register-face must be approximately 1.8 this amou or 518 sq in, to obtain the same free area through the register-grill as exists the flue or duct. Sizes of standard registers are given in the section on Fu nace-Heating.

Direct Hot-Water Heating

Systems in Use. Systems for heating with direct hot-water radiators, l the direct steam heating systems, may be divided into two general classes, t first of which includes all those systems OPERATING BY GRAVITY ONLY, dependi on the difference in density of the water-columns in the flow and return-lines cause circulation. The second class includes those systems in which a FORCE CIRCULATION is maintained by means of a pump placed on the return-line ju before it enters the boiler or heater. These latter systems are employed usual only in large installations or in district-heating service.

Gravity Hot-Water Heating Systems. The gravity systems are divid into the UPFEED SYSTEMS, using basement-mains, and the DOWNFEED SYSTE using overhead or attic-mains. The upfeed systems may have either a one-pi basement-main or two-pipe basement-mains, and the latter type may ha either a DIRECT or a REVERSED return-main. (See Figs 38 and 39 for revers

ifeed systems may have either SINGLE OR DOUBLE RISERS.
be operated with an OPEN or CLOSED EXPANSION-TANK,
? to 46. In general, the downfeed or overhead systems are
it the use of smaller mains and risers, and provide for the
of air from the radiators and piping. It is necessary, how-
oom or clear space in the attic should be at least 4 or 5 ft if
and branches are to be properly installed. It is sometimes
verhead mains at the ceiling of the top floor, and in such
striction does not apply. Mains run in attics must be
revent freezing. The underfeed systems are used where

supplying only upper-floor radiators. It will be seen that in the case of branc supplying radiators on all floors the upper-floor radiators may be made to r

culation of the first-floor radiators by taking the basement-ter from the side of the branch running to the latter radiator. ach is usually run full size all the way to favor the lowest in Fig. 45. After having served all the radiator-branches nd returns to the boiler, continuing the same size for the nnections (Fig. 43) to radiators should be made at the TOP using a union elbow, and at the BOTTOM on the return-end, ing hot-water radiator-valve with union connection. By nly one valve is required to control the radiator. Since the water in the one-pipe main gradually drops, due to the return temperature from the radiators served in the course of the uilding, it is advisable to increase the last radiators on the o in area and to increase the size of branch and riser-connec-the main by a one-pipe size. Pipe-sizes may be taken from XXXIII. In using the tables all mains must be measured and risers to any floor are proportioned to supply all the it floor as well as the radiator actually installed on that Figs. 43 and 45.

Table XXXIII was compiled by J. J. Hogan, and is to be used for either one or t pipe work.

VERSED-RETURN SYSTEM each group of radiators has exactly the same lengt water-travel, and hence the resistance to be overcome is practically the sa irrespective of the distance of the radiator-group from the boiler. It wil noted that the return begins at the first radiator served and flows in the s DIRECTION as the flow-main, increasing in size while the latter decreases. flow-main grades UP uniformly ¼ in in 10 ft, and the return grades DOWN to the boiler with the same pitch. Pipe-sizes may be taken from Tables XX and XXXIII as in one-pipe work, and the main-size reduced or increased rapidly as the change in radiation supplied will permit. It is also custo in government work to install a STARTING-PIPE (Fig. 38), between the main and return at the boiler, in underfeed systems. This pipe ranges from 1¼ 2½ in in size, depending upon the capacity of the boiler, and is intended to a in the establishment of an initial circulation between flow and return-head even before the water in the mains is moving.

Equalization-Table. In Federal-building work N. S. Thompson makes of the following Equalization-Table in proportioning mains and risers serv more than one radiator in both upfeed and downfeed systems. The eq izing-numbers represent the relative capacities of the different sizes of pipes

Table XXXIV. Equalization-Table for Mains and Risers

in	in	in	in	in
½ = 2	¾ = 5	1 = 10	1¼ = 20	1½ = 3
2 = 60	2½ = 110	3 = 175	3½ = 260	4 = 3
5 = 650	6 = 1 050	7 = 1 600	8 = 2 250	....

Example. A 1¼-in, 1½-in and 2-in pipe have a total value of 110 units, and are equivalent in carrying capacity to a 2½-in main.

me friction-pressure loss per 100 ft of run, and are proportional to the 5/2 s of the diameters. Thus the weight of water flowing varies as shown by lation, $W = Kd^{5/2}$, in which W = weight, I = a constant, and d = pipe-ter.

ails of Piping Systems and Connections for Direct Hot-Water ng. The distinctive piping-details of each system of hot-water heating been discussed under that system, as described in the preceding para-. In general all main piping and branches must be UNIFORMLY GRADED, ady indicated, and ample provision made for EXPANSION and CONTRACTION, ready REMOVAL OF AIR from all parts of the system. Air-traps or pockets t-water system are fully as serious as water-pockets in a steam system. a hot-water main grading down in the direction of flow cannot be relayed an air-outlet is provided at the top of the relay. If the main is reduced at any point an ECCENTRIC FITTING must be used to keep the TOP of the nd small main in the same plane and avoid an air-pocket. Not only l the piping be designed to permit the removal of air, but FREE AND COM-DRAINAGE of water must be provided for as well, so that when the drain -off cock is opened at the boiler the entire system can be emptied of water. ch-mains are taken from a HEADER at the boiler they must all rise to the LEVATION so that the tops of all the branches will lie in the same plane start away from the boiler. The fittings on all main piping and branches of the long-sweep pattern, and all pipe should be carefully reamed to burrs and sharp edges. Where the same riser supplies radiators on two floors the branches to the radiators on the intermediate floors may be ed with special tees (Fig. 41) known as O. S. FITTINGS, with a deflector l to divert the current of flow into the outlet of the tee, and thus favor iators on the intermediate or lower floors. By using TOP-FLOW and RETURN CONNECTIONS at each radiator it is possible to positively control t by a single valve, except for the slight circulation intended to prevent which takes place through the 1/16-in-diameter hole drilled in the valve-leeve, when the valve is closed. If both connections are made at the tappings, and only one valve is used, it is entirely possible that the may still be supplied with hot water through the unvalved connection en the valve is closed.

emoval in Hot-Water Systems. Suitable provision must be made for val of air from all hot-water radiators, wherever an upfeed system is Usually small air-cocks are attached to the highest point of each and are periodically opened to relieve any accumulation of air. If ks are forgotten a radiator may become air-bound and fail to heat f faulty circulation; hence automatic air-valves are sometimes installed purpose. The automatic air-valve for hot-water radiators is not very used, due to its liability to pass water as well as air; but a standard le by the Monash-Younker Company, may be mentioned.

sion-Tanks for Hot-Water Heating. Open-Tank Systems. The are system of hot-water heating is not a closed system, as provision made for expansion and contraction of the water within the system. ank is provided at a suitable elevation, not less than 3 ft above the diator, and connection made to the nearest return-riser; or preferably expansion-line is run to the flow or return-main in the basement. F THE EXPANSION-TANK varies with the amount of water in the system, vith the range in temperature of same, and its capacity is determined

rease in volume of a given weight of water heated from 32° to 212° is

about $\frac{1}{23}$, or approximately 4.33%; so that for every 23 gal in the system 32°, an allowance of 1 gal must be made in the expansion-tank when the wa in the system is raised to 212°. Cast-iron radiators have an internal volume 1½ pints per sq ft, while steel radiators and 1-in pipe hold about 1 pint per sq Assuming the internal volume of the radiators to be about 50% of the en system, we have for 3 000 sq ft of actual radiation, 3000 × 2 × ⅛ gal = gal of water. This water will increase $\frac{1}{23}$ × 750 = 33 gal on being hea from 32° to 212°. Hence an expansion-tank of 2 × 33 = 66-gal capacity necessary, the tank being made double the theoretical volume for practi considerations.

A list of expansion-tank capacities and dimensions is given in a ta (included with Figs. 42 to 46), from which a commercial tank may be read selected for systems under 6 000 sq ft. For larger systems the size of ta should be separately determined and the nearest commercial tank-size, as tal from the manufacturer's list, should be specified. These tanks should hav or 1¼-in top and bottom tappings with ½-in water-gauge tappings, for c necting a gauge-glass, at least 12-in long, on the side of the tank as shown Fig. 43. The tank must be securely supported well above the highest radia in the system, and in the larger installations special framing must often designed to carry the weight of tank and water. Automatic expansion-ta equipped with a ball-cock and overflow are sometimes installed, and the altitu gauge on boiler, and the gauge-glass and fittings on tank omitted. These ta may be covered with hardwood and varnished if it is necessary to place them i finished room or apartment.

Expansion-Tank Connections. The most approved method of connect an expansion-tank to a low-pressure one-pipe system is shown in Fig. 43, wh an expansion-and-vent line is run from the top of the main, at the high p just above the boiler, and connected to a return-bend just beneath the ta A return circulating-line is taken from the other side of this bend and connec with the return-main at the boiler. The circulation of water in this loop prevent freezing at the tank. From the top of the tank a 1¼-in vent-lin taken through the roof, and a 1¼-in overflow is taken out of this vent-line tee just above the tank. This overflow should discharge into an open sink drain near the boiler so that it will be immediately evident to a person in boiler-room, filling the system, just when the water has risen to the overf above the tank. The movable hand on the boiler altitude-gauge can then be to correspond with the middle of the gauge-glass, and the water-level brou to this point with the system cold. No valves should ever be installed on ei the expansion or the overflow-lines, and in case the system is valved at the bo the expansion-line must be connected on the boiler-side of this valve; and wh two boilers are installed this line must be carried to a point above the wa line in the expansion-tank to prevent siphoning the water out of the en system in case it is necessary to drain only one boiler. Expansion or vent-connections must always be so made to main-piping in basement so that ai will be automatically removed from high points. Wherever possible rise branches to risers may be used for relieving any accumulation of air in the m piping. In SMALL INSTALLATIONS the expansion-line may be connected to return-riser of one of the highest radiators, and no overflow other than the need be provided for, as shown in Fig. 46. This is a cheap method, and sh not be resorted to unless extreme economy must be practised. The tank be in the same room with the radiator to prevent freezing, as no circulati provided for, and the overflow is simply discharged out of doors and us upon the roof. The usual result is that an unsightly appearance is soon cre

The United States Treasury Department employs a special vent and overf

) in cold climates, where there is liability of the vent-line freez-rough the roof, due to the condensation and freezing of vapor h this line. The vent-line is made only 2 ft high above the :pt within the building, and it is equipped with a check-valve ıpe of water through the same in case the tank should sud-he closing of the check-valve will compel the excess water to flow, and prevent the flooding of the building.

rstems. The PERMISSIBLE TEMPERATURES in any hot-water ›y the pressure on the system, which latter factor determines ›oiling will take place. The pressure at any elevation in an ɜr system will vary directly with the distance below the level ɜxpansion-tank, and hence it will be possible theoretically to he boiler at a temperature corresponding to the hydrostatic r before boiling would occur. The relation between hydro-and boiling-point are given in the following table:

ion between Hydrostatic Head, Pressure and Boiling-Point

0	12	24	37	49	61	74	87	100	113	125
0	5	10	15	20	25	30	35	40	45	50
212	227	239	250	259	268	274	281	287	292	298

l be quite impossible to carry temperatures in excess of 212° ı-tank system, as the high-temperature water would imme-›pen tank and boil. In order to overcome the limitations ›em, in which water will always boil as soon as a tempera-ached, various means of increasing the pressure in these sorted to in the attempt to carry a higher water-tempera-n very cold weather than would be possible with an open-devices have usually been installed on the expansion-line, r else just below the expansion-tank and the static head ing a column of mercury in the path of the expanding the expansion-tank.

the apparatus, known as the HONEYWELL HEAT-GENERA-44, in which it is seen that water entering the generator ›rce the mercury up the inner tube *A* until a head of 20 in at which time the entrance to this tube will be uncovered ater or air may enter it and pass to the expansion-tank. above that required to just fill tube *A* is returned by tube ıe base. When the system cools off water can flow back s the mercury-column drops in it, and the slight head of at the outlet of this tube is easily overcome by the head ›n-tank above this point. This increase of 10 lb in static sible to carry a maximum water-temperature of 240°, ı would be possible in an open-tank system. While a this could theoretically be carried AT THE BOILER in an a static head of 24 ft, just as soon as this water rose in the ınd escape from the expansion-tank, at the same time f water. In fact with the open-tank system the water t at a temperature of 212° F. The use of pressure-gene-bove makes it possible to use smaller radiators in the

heated rooms, as it is entirely possible to maintain steam-temperatures in t radiators whenever desired. Since higher temperatures are used, the differe between flow and return-riser temperatures becomes greater than in the op tank system, and hence a greater motive head exists and smaller mains a risers may be used with this system. The HONEYWELL COMPANY recomme the following schedule of radiator-tappings:

Table XXXVI. Riser-Sizes for Honeywell System

Pipe-size in inches	Capacity in square feet of hot-water radiation		
	1st floor	2nd floor	3rd floor
½	30	40	50
¾	75	100	125
1	75 up	100 up	125 up

It should be remembered that since radiators and pipes are smaller in t system there is much less water than in the open-tank system, making it m sensitive in warming up and also in cooling off. The GENERATOR should not placed close under the expansion-tank. Otherwise than this its location may anywhere in the expansion-line, as the same hydrostatic head is always act in addition to the head of mercury-column.

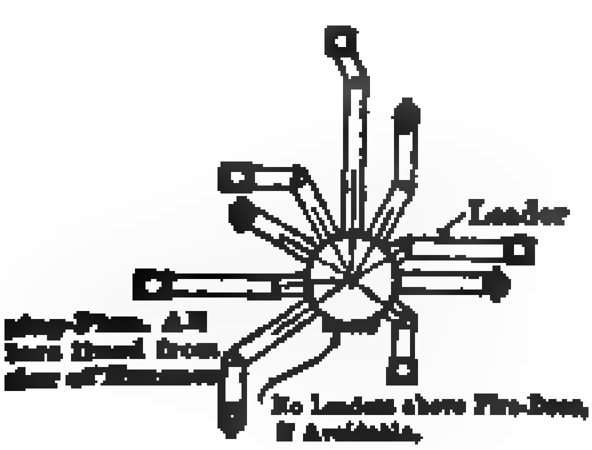
Furnace-Heating

The Furnace and Its Location. The method of warming or heatin building by what is generally known as a warm-air furnace is termed FURNA HEATING. The furnace consists briefly of a cast-iron or steel heater, contai a COMBUSTION-CHAMBER, FIRE-POT and GRATE. The heater is usually set a encased by a double-wall galvanized sheet steel JACKET (Fig. 47), although b is sometimes used instead of the steel jacket for this purpose. Furnaces soft coal are usually designed with a secondary air-supply or OVERDRAFT admitting heated air just at the surface of the fire in order to produce a m perfect combustion of the volatile combustible gases which are liberated fr this fuel immediately after firing. This overdraft should be under positive c trol so that it may be checked or closed after the fuel has been coked. Soft c may also be burned efficiently in the underfeed-type of furnace in which coal is from below by means of a plunger operating in a feed-chute discharging thro the center of the grate. The furnace should be located in the basement in approximately central position with reference to the rooms to be heated, a preferably toward the side or sides from which the prevailing winds blow in winter-time. This arrangement not only favors the more exposed rooms on floors above by shortening the leaders to these rooms, but also makes it poss to reduce the length of the cold-air duct, which should always be run from exposed side of the building to the cold-air pit below the furnace. (Figs. 53 54.) In operation cold air is drawn from the outside through the COLD DUCT, passed through the space between the heater and its jacket, and wa by coming in contact with the outside heated surface of the combustion-cha and the radiator, which is usuallly just above the combustion-chamber. I

discharged through flues connected at the top of the JACKET, FURNACE-CAB-
INET to the rooms to be warmed.

Fig. 47. Warm-air Furnace with Galvanized Sheet Steel Jacket

lers and Stacks. These connecting flues are made up of two sections, nearly horizontal round pipes in the basement, known as LEADERS (Figs. 49), which connect to the COLLARS on the top or conical sides of the



. Warm-air Furnace-leaders with Elbows

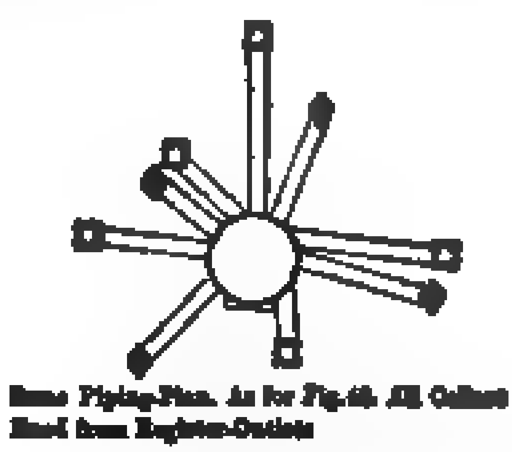


Fig. 49. Warm-air Furnace-leaders without Elbows

and (2) the vertical rectangular pipes called STACKS (Fig. 50), which he BOOT at the outer end of the leader, with the double-walled REGISTER- . 51) into which the REGISTER-GRILLE covering the opening into the room. The leaders should have an upward pitch toward the base of the

stack of at least 1 in per foot, and for the best results they should not be m than from 12 to 15 ft in length. The boots are made in a great variety of sha to suit actual conditions, and are simply ADAPTERS for the purpose of changi from round leaders to re angular stacks. The sta are usually run between t studding of interior walls partitions (Figs. 50 and 5 since if they are placed outside walls the cooling eff reduces their efficiency n only in temperature of a but also in velocity of fl The METAL used for lead and stacks is usually bri IX tin, although for lead larger than 12 in, galvani steel of No. 26 United Sta Standard gauge is usu employed. The covering all leaders, boots and stac as well as the furnace itsel most important, and eith heavy grade of asbestos pa is pasted on the outside, as in the case of leaders a the furnace itself, asbes air-cell covering, about ½ thick may be used and secu with brass bands or w Since the stacks must generally, in a 4-in studd space, with a net depth about 3¾ in, every ef must be made to keep th as deep as possible; and t lathing or expanded me should be used in front of such stacks, which ordina have only a single layer of asbestos-paper covering. A more effective insula may be provided by using a DOUBLE-WALL STACK, in which there is an air-s between the inside and outside pipes, and no asbestos covering is used. Table XLII for this equipment, as made by the Excelsior Steel Furn Company. Attention of the architect is here called to the fact that in the c of large second-floor rooms to be warmed by one register, 6-in stud partiti are generally required for the first floor.

Fig. 50. Vertical Stack with Side-wall Register

The Design of a Furnace Heating System.

Heat-Loss and Air Required. The determination of the size of the furn and the connecting leaders, stacks, registers, ducts, etc., is based on: (1) t actual heat-loss from each room in the building, including wall and glass-tra mission losses, as well as loss due to infiltration; and (2) the amount of air t circulated per hour, which in turn is based on this heat-loss. A buildin

by hot air by introducing the air into the rooms at a higher that required to be maintained in the rooms at the breathing-ly 70° F.) The air in cooling gives up per pound, 0.24 Btu r at con-'or each empera-ray sup-ssary to ansmis-tc., and rovides air for maxi-of the ter-cap 90° F., egisters a drop 15° be-bonnet These ximum eeded.

Fig. 61. Vertical Stack and Register-box

If the air is all drawn from the outside, and the re is 0°, then the air is heated from 0° to 190°, and the room, from 175° to 70°, or 105°. In other words, 0.24 s apparently thrown away, for every pound of air circulated. e brought in from the outside in order to supply a sufficient on, then this is the price which must be paid for ventilation, same, no matter what system of heating is employed, for tion. It is almost invariably the case, however, that a con-the air may, if desired, be recirculated, in which event, for ect, the furnace system of heating requires no more expendi-rm of fuel burned than a direct steam or hot-water system, as economical to operate when correctly designed, installed head producing the flow or circulation is due to the differ-en the ascending column of heated air and the weight of an the colder intake air The system may be proportioned f the air during the extreme cold weather.

be Circulated per Hour. It is first necessary to deter-r required per hour which must be supplied to each room.

's of air to be circulated per hour;
temperature to be maintained;
ature of air leaving the registers (assumed 15° lower than temperature leaving the furnace-cap or bonnet),
be supplied to room per hour as determined by heat-loss culations;
ven up per pound of air circulated.
$4(t_d - t)]$.
'or t_d is 175° F., and $t = 70°$ F.

of air, entering at temperature 175° = .063;
et of warm air entering room per hour
$= H/1.58$.

Heat Required from Heater per Hour, Based on Recirculation. Th heat required per hour from the heater will depend on the temperature of th entering air and will be a maximum when all the air circulated is taken fro the outside and a minimum when all of the air is recirculated.

Let h = Btu required from heater per hour;
t_e = temperature of air entering heater = 65°;
t_h = temperature of air leaving heater = 190°.

Then $h = 0.24\,W(t_h - t_e)$.

Substituting the values given above for W, t_h, and t_e,

$$h = 1.2\,H.$$

Size of Furnace. The capacity of a furnace for heating air depends primari upon the amount of coal that may be burned per hour, which is the product the RATE OF COMBUSTION by the grate-area. With an assumed or fixed rate combustion, the capacity of the furnace is dependent upon the grate-area. Th grate-area is therefore used as a basis for the rating and comparison of warm- furnaces. The average rate of combustion usual in furnace-heating rang from 3 to 4 lb per sq ft of grate-surface per hour, but in zero weather this ra may run as high as 6 lb, and is readily obtainable with the ordinary height residence-chimney; that is, at least 35 ft. A properly designed furnace w have a combined furnace and grate-efficiency of from 55 to 60%. Higher ef ciencies have been obtained in tests.

Commercial Ratings of Furnaces. Manufacturers rate their furna according to the amount of space, cubical contents, in the ordinary residen construction they will heat to 70° F. in zero weather. Maximum temperatu of air leaving registers = 175° F. The detailed dimension and capacity-da other than grate-area and space heated, of most furnaces are seldom publish by the manufacturer, although there are a few notable exceptions. The act size of the furnace naturally depends upon the heat-transmission of the wal floors and roofs, plus the infiltration-losses, as already explained. The cla however, is made that these "in turn bear a reasonably uniform relation to t cubical contents of the ordinary house," with the usual proportions and rat of wall to glass-surface, and that therefore the rating, as given, is justifia Tables XXXVII and XXXVIII were taken from the Warm Air Furnace Han

;-diameter should be such that the minimum cross-sectional area M, ; and radiator, will be at least 20% greater than the total cross-sectional heat-pipes, a, or $M = 1.2 \times a$ sq in.

ied by the Federal Furnace League, an association of United States ifacturers. This association is no longer in existence. If the he basement or leader-pipes exceed 12 ft in length or have less than e foot, or if more than one sixth of the outside surface of the building the furnace should be increased one or more sizes. The size of the iired can also be determined by the combined area of the cross- he warm-air pipes.

Rating Based on Efficiency and Rate of Combustion. The ir that a furnace is capable of imparting to the air (not the room) : estimated from the grate-area by assuming that the average coal intain approximately 12 000 Btu per lb. A combined furnace-and- ncy of 55%, and a maximum combustion-rate of 6 lb per sq ft of iour for maximum conditions (coldest weather) are also usually

urface Required, Based on Recirculation. The area of the dily calculated as soon as the heat to be supplied to the building per een determined.

H = Btu to be supplied building per hour;

h = Btu required from furnace per hour for heating the air = .12 H;

C = heating value Btu of coal per lb;

E = combined furnace-and-grate efficiency;

R = rate of combustion, pounds of coal per square foot of grate-surface per hr;

G = grate-area in square feet;

$h = G \times C \times E \times R = 1.2\,H.$

h = area of grate in square feet $\times$ 12 000 $\times$ 0.55 $\times$ 5.5
= 36 300 $\times G$. which is Btu transmitted to the air passing the furnace;

$G = (1.2 \times H)/36\,300.$

he usual assumptions, with ANTHRACITE FUEL are:

$C = 12\,000$ Btu per lb;

$R = 4$ lb ordinary rate and 5.5 lb for maximum conditions in coldest weather;

$E = 0.55$;

hen $G = h/(12\,000 \times 5.5 \times 0.55) = h/36\,300 = 1.2H/36\,300.$

ize of Leaders and Stacks. The area of the air-pipes (leaders and stacks) uired for a room depends upon the quantity of air to be indroduced per min- and the velocity with which the air will flow with natural circulation.

$Q/60$ = cubic feet of warm air to be introduced into the room per minute;
V = velocity of air in feet per minute attainable;
H = heat-loss of room;
A = area of pipe in square feet;
$Q/60 = AV$, and substituting value of $Q = H/1.58$;
$A = H/(95 \times V)$.

e following velocities are approximately obtained in the leaders and stacks he floors as stated:

First floor, 175 ft per min;
Second floor, 240 ft per min;
Third floor, 310 ft per min.

e above velocities have been observed in practice in well-designed systems. for various floors, substituting in the above equation, in square inches:

$A_1 = H/115$ for first-floor pipes, leaders and stacks;
$A_2 = H/160$ for second-floor pipes, leaders and stacks;
$A_3 = H/206$ for third-floor pipes, leaders and stacks.

Bulletin No. 112, Engineering Experiment Station, University of Illinois,

ual leader and stack-sizes are based on the above areas, using the nearest ch for leader the diameter (Table XL), and keeping the stacks of such rtions that the cross-sectional dimensions are never in a greater ratio to 1. For example, a stack 4 by 20 in is seldom effective over its full area, s too narrow, and as its large rubbing-surface causes excessive friction. ctual velocities obtained, however, will depend upon the head or pressure g the flow and the friction-head, and will seldom exceed 50% of the theoret- elocities. Table XL has been recommended by the Federal Furnace and gives the sizes of round pipe for leaders, the size of wall-pipe for and free areas of registers to connect with same. Leaders over 12 ft in should be increased 1 in in diameter for each 5 ft beyond 12 ft.

isters. The FREE AREA through the ordinary register-grille is only ap- ately 55% of the gross area, and consequently a register must be selected s a gross area of double the area of the pipe with which it connects, in hat the air-passage may not be contracted and the capacity reduced. rcial register-sizes are based on the actual inside dimensions of the grilled and are made either of pressed steel or cast iron, with a variety of fancy grilles. The plain rectangular grille is to be preferred, finished to suit orative scheme, in black japan or electro-plated in brass, bronze or finish. Warm-air registers may be placed in the floor, but preferably e partitions, for first-floor rooms. By using the modern BASE-BOARD R, Fig. 52, it is usually possible to secure the required capacity without

* When the required size of pipe falls on the odd half-inch (as 7½, 8½, 9½, etc.), the size may be increased to the even inch (as 8 instead of 7½, 9 instead of 8½, etc.), for the first-floor rooms and bath-rooms; provided that the pipes for upper-floor rooms other than bath-rooms, be decreased by ½ in when the required sizes fall on the odd half-inch. It is better, however, to use pipes of the sizes given in the above table, with proper allowances for length of pipe, extra bends, etc., beyond straight runs 12 ft long.

resorting to floor-registers. These base-board registers can be connected to a flue from 3 to 4½ in deeper than the studding. This has been accomplished by making the special base-board register so that it projects 2 in into the room at the floor-line, necessitating the cutting out of the floor, and also utilizing the space of about 1 in occupied by the lath and plaster, or a total increase in depth of flue of about 3 in. For upper-floor rooms registers should be placed in inside partition walls, using CONVEX REGISTERS for shallow stacks. As a general rule warm-air registers should be so placed as to shorten leader and stack-connections as much as possible. The use of a floor-register may be permitted in an entrance hall for drying shoes and garments, but it is unsanitary and cannot fail to collect dirt and filth of all kinds. In case such registers are used, however, suitable REGISTER-BOXES must be provided, and they are preferably constructed with double walls.

Example in Furnace-Heating. A gravity furnace-heating system is to be designed for the two-story frame building shown in Fig. 55, with inside and out

net area of register-faces is assumed to be 55% of the gross area. The gros als 1.8 times the area of the leader-pipe.

by 36 300, the heat available from 1 sq ft of grate when burning 5.5 lb of coal of 12 000 Btu heat-value per pound, at 55% efficiency, gives 4.1 sq ft as the grate-area. This will require a grate of 28-in diameter. This building has a net volume of 26 000 cu ft, and by reference to Table XXXVII it is seen that a 28-in grate is recommended for this amount of divided space. The furnace, in this problem, has been located practically in the center of the house, but on the north side of its east and west axis, giving a direct cold-air connection from the north wall and short direct runs for most of the leaders.

Leader-Layout. The leaders may be laid off, as shown in Fig. 55 and in Fig. 48, by dividing up the circumference of the bonnet into areas proportional to the amount of air to be distributed by each leader, and then connecting collar and leader radially to furnace-cap, making one or more elbows in the leader, if necessary to connect with stack. Another method is to run practically all leaders direct from furnace to foot of stack (Fig. 49) and cut the collars in on the angles at which they intersect the casing. The former method is recommended and requires less skill in installation. The basement heating-plan is shown on the first-floor plan, which also shows all stack-sizes to both floors. Floor registers have been shown on the first-floor plan in order to simplify the layout and make the plan clearer. In general, base-board registers are to be preferred. The sum of the areas of leader-pipes is 927 sq in.

Hot-Blast Heating

General Features. The mechanical indirect method of heating, commonly known as the BLOWER SYSTEM OR HOT-BLAST SYSTEM, particularly adapted to the warming and ventilating of large structures, is made up of three units: (1) a HEATER constructed of pipes, tubes, or cast-iron sections, through which steam, hot water or hot gas may be passed. (2) A FAN OR BLOWER to circulate air over the heater-surfaces, the air acting as a heat-carrier or medium of heat-transfer. (3) A SYSTEM OF DUCTS OR PIPES to convey the heated air from the heater to points where heat may be required. When the heater is located between the fan and main duct, the combination is termed BLOW-THROUGH, and when the fan is installed between the heater and the duct, the arrangement is known as DRAW-THROUGH. These two arrangements are shown in Fig. 57. The DRAW-THROUGH combination is more often used for shop and factory-installations where compactness is desirable, the BLOW-THROUGH combination being used principally for HOT-AND-COLD systems as installed in schools and public buildings.

Advantages of the Blower or Hot-Blast System. The advantages of the blower or hot-blast system over those of direct radiation, briefly summarized are:

(1) When ventilation is a requirement in order to maintain a healthful atmosphere, this method affords a positive means of accomplishing this particularly desirable result, which is entirely independent of the changing climatic conditions.

(2) When a standard humidity of the air is to be maintained, a feature which is becoming to be more generally recognized as desirable in any heating-and ventilating installation, and quite essential to the successful manufacture of some materials, the humidifying-apparatus may readily be made an integral part of the system.

(3) A much smaller amount of radiating-surface is required to perform an equal heating-duty, with a consequent reduction in the number of steam-tight joints, unions and valves to keep in repair.

(4) The air-leakage being mostly outward, the building will in general be in

m drafts and more uniformly heated. If the air is simply recirculated, no ih air being taken into the heating system from the outside, the above statent does not apply. The pressure of the air in the building, even when all of air is taken into the heating system from the outside, is comparatively feeble, some air will enter by infiltration through the window and door-cracks on windward side of the building, although the statement is often made that leakage being all outward, prevents the infiltration of cold air from the iide.

) This system is more easily regulated, and readily responds to changing ide temperatures.

) The air entering for ventilation may be conveniently cooled in summer, r by the circulation through the heater of cold water or of brine previously d by mechanical refrigeration.

) Simply running the fan will in itself greatly relieve the oppressiveness in hot y weather, and when cold water is circulated through the coils the difference ry noticeable.

pical Arrangements. When ventilation is not a requirement, or when it is vely unimportant, as is frequently the case in shop or factory-heating where umber of persons vitiating the air is small compared with the cubical con- of the building, the air may be simply RECIRCULATED, sufficient fresh air ntilation being supplied by infiltration. The amount of heat to be sup- the heater in this case is the same as would be required for a direct-radiation lation. When ventilation is a requirement to be met a COLD-AIR INTAKE vided. Since the amount of air necessary for heating is generally in excess amount required for ventilation considerable economy may be effected by ılating a portion of the air. In this case only sufficient fresh air is drawn he system from the outside to meet the ventilation requirement and the ıder of the air necessary for heating, is recirculated. This may be readily d by an arrangement of ducts and dampers on the suction-side of the fan. fresh air introduced is to be washed or conditioned the washer or humid- ıd tempering-coil may be added between the inlet for the recirculated air e fresh-air intake.

ount of Air to be Circulated for Heating. The weight of air to be cir- l per hour for heating a room or building is found by dividing the heat-) by the amounts of heat given up by 1 lb of air in cooling from the tem- re at the duct-outlets to the mean room-temperature.

H = heat-loss of room, Btu per hr;
M = weight of air to be introduced in room per hour;
t = mean inside temperature;
t_d = temperature of air leaving duct-outlets.

$$M = H/[0.24(t_d - t)]$$

temperature t_d depends upon the temperature of the air entering the the velocity through the clear area, the amount of heating-surface and perature of the steam. This temperature in practice ordinarily ranges 5° to 150° F. and may be readily determined for any specified condition data given later under Hot-Blast Heaters. The temperature of the air the duct-outlets for ordinary installations, when the ducts are not run ound or in outside walls, may be assumed to be the same as the tempera- of the air leaving the heater. Any loss in temperature in this case vard heating the building and is therefore not a direct loss. If, how- e ducts are run underground or in outside walls, a considerable loss in

temperature may occur, which is a direct loss, and must be provided for by INCREASING THE TEMPERATURE OF THE AIR LEAVING THE HEATER by an amount equal to the estimated temperature-drop in the ducts.

Temperature of Air Entering Heater.

Let t_1 = temperature of air entering heater;

t_0 = outside temperature;

t = mean inside temperature;

t_2 = temperature of air leaving heater;

(a) When the air is all recirculated, $t_1 = t$;

(b) When fresh air only is circulated, $t_1 = t_0$;

(c) When a portion of the air is recirculated the resulting temperature of the mixture of fresh and recirculated air may be found by the METHOD OF MIXTURE

Let M_v = weight of fresh air, pounds required per hour for ventilation (30 cu ft per min per person);

= 0.075 × 1 800 × number of persons (usual requirements);

M_r = weight of air that may be recirculated;

$M = M_v + M_r$

$H = 0.24\,(M_v + M_r)\,(t_d - t)$.

Having assumed or fixed the value of t_d, the only unknown quantity is M_r.

$$M_r = H/[0.24(t_d - t)] - M_v$$

The temperature t_1 may then be found as follows:

$$M_v \times (t_0 + 460) = A$$
$$M_r \times (t + 460) = B$$
$$(M_v + M_r)\,(t_1 + 460) = A + B$$

or

$$t_1 = (A + B)/(M_v + M_r) - 460$$

Example. The heat-loss H for a certain factory-building is 70 600 Btu per hr. The number of men employed is 50. Mean inside temperature $t = 65°$ F. Outside temperature $t_0 = 0°$ F. Ventilation is to be provided at the rate of 1800 cu ft of fresh air per hour per person. Assumed temperature of air leaving duct-outlets is 135° F.

Solution. $M_v = 0.075 \times 1800 \times 50 = 6\,750$ lb per hr fresh air for ventilation. The weight of air that may be recirculated is

$$M_r = 706\,000/[0.24(135 - 65)] - 6\,750 = 35\,273 \text{ lb per hr}$$

The temperature of the air entering the heater will be:

$$6\,750 \times (\,0 + 460) = \;3\,105\,000$$
$$35\,273 \times (65 + 460) = 18\,516\,750$$

$$t_1 = (21\,621\,750/42\,023) - 460 = 55° \text{ F.}$$

If FRESH AIR ONLY is to be used, as in school-house and public-building heating, the weight of air to be circulated is determined directly by the ventilation requirement.

Then $M = M_v = H/[0.24(t_d - t)]$, or $t_d = (H + 0.24\,M_v t)/0.24\,M_v$

Temperature of Air at Duct-Outlets. When heating, by the hot-blast system, a building containing a number of rooms having different heat-loss and ventilation requirements, it is obviously impossible to maintain the de

perature by controlling the temperature (t_h) of the air leaving the heater at point. The temperature t_d of the air leaving the duct-outlets will ordinarily different for each room in the building, as shown in the following example. result is accomplished by the double plenum-chamber system described .

ample. Let it be required to determine the temperature of the entering t_d) to offset the heat-loss and provide ventilation for the several rooms as in Table XLVII. Inside temperature (t) to be maintained is 70°.

Table XLVII. Data for Example

oom-mber	Number of occupants, n	Ventilation		Heat-loss, H	Temperature of entering air, t_d (see formula)
		Cubic feet per hour at 70°, 1 800 × n	Weight per hour, M_0		
-1	50	90 000	6 750	32 000	89.5
-2	53	95 400	7 125	21 000	82.2
[all	....	30 000	2 250	4 000	77.4

perature of Air Leaving Heater. If all of the air is first warmed by the ING-COIL to 70° F., and a mixture of approximately (1 − x) parts of ed air and x parts of hot air is to be used, then the required temperature of air leaving the heater may be determined, for any particular case, by THOD OF MIXTURES previously given; or, assuming this temperature, the ions of hot and tempered air may be determined.

ple. Required the temperature of the hot air (t_h) leaving the heater for − 2, (Table XLVII) if the mixture entering the room is made up of tempered air at 70° and one half hot air. The total weight of air the room is 7 125 lb per hr, or 3562.5 lb of tempered air and 3562.5 lb r.

on. $3\,562.5 \times (70+460) + 3\,562.5 \times (t_h + 160) = 7\,125 \times (82.2 + 460)$.
$= 94$.

ing a temperature of $t_h = 120°$, it is required to determine the relative ons, by weight, of the mixture required.

= parts of hot air in mixture. Then $(1 - x)$ = parts of tempered air.

$$x(120 + 460) + (1 - x) \times (70 + 460) = (82.2 + 460)$$

$$x = 0.244 \text{ and } (1 - x) = 0.756$$

pplied for Ventilating Purposes Only. A combination of direct radia- ffset the heat-loss H, and a hot-blast system, to supply the fresh air r ventilation, is sometimes installed. In this case it is customary to eater of sufficient capacity to warm the air for ventilation to about 80°. r used for this purpose is made three sections deep and is often termed a G-COIL

d-Cold Systems. In order to accomplish the results required in the example, the so-called HOT-AND-COLD SYSTEM or DOUBLE-PLENUM-SYSTEM is used. All of the air drawn into the system from the outside

is first passed through a TEMPERING-COIL, which is designed to heat the air to approximately 70°. A portion of the tempered air is then passed through a heater and raised to 125° to 150°. Then if varying proportions of the hot and

tempered air are correctly mixed the resulting temperature (t_g) is readily controlled without varying the quantity of air discharged, which evidently must remain constant on account of the ventilation requirement. There are two

thods of distribution used, as shown in Figs. 56 and 58. Referring to Fig. 58 seen that the hot and tempered air meet at the end of the plenum-chamber he entrance to the ducts, and the temperature of the mixture is controlled he MIXING-DAMPERS, which may either be hand-operated or placed under matic thermostatic control. It will be observed that the plenum-chamber vided, and that each duct serving a room has its own independent set of ng-dampers. This method of distribution is known as the SINGLE-DUCT EM and is frequently employed where the installation of the DOUBLE-DUCT EM, as described below, is not feasible or is undesirable. Fig. 56 shows a le set of ducts run from the plenum-chamber to the base of each vertical one carrying the hot air and the other the tempered air, the mixing being at the base of the flue as shown The mixing-dampers (Fig. 60) may be olled by hand by means of a chain carried up the flue and run into the at a point several feet above the floor-line, or placed under automatic mostatic control through the medium of a compressed-air-operated damper.

Hot-Blast Heaters

e-Coil Heaters. The type of heater that has been a standard for a er of years, for hot-blast work, is made up of four or eight vertical rows,

Fig. 61. Pipe-coil Heater-base

ng on the manufacturer, of 1-in pipe screwed into a cast-iron base and rom 2 1/8 to 2 3/4 in on centers, the pipes in each row being cross-connected op by the use of nipples and ells. The arrangement of coils and the of dividing the base by a vertical partition, running longitudinally, in separate the supply and return as used by the American Blower Com- shown in Fig. 61. A base with its accompanying pipes is termed a

SECTION. The heater is made up of a number of such sections enclosed b[y]
SHEET-STEEL JACKET, usually No. 22 gauge.

Cast-Iron Indirect Heaters. Special cast-iron sections for indirect hea[t]
are often used, and Fig. 62 shows a cast-iron heating-unit or section, na[m]
Vento, manufactured by the American Radiator Company, which is quite wi[d]
used in this class of work. A STACK made up of several sections has a sma[l]
number of joints than a pipe-coil section of equal heating-surface. The det[e]
oration of the cast-iron sectional type of heater is practically nothing except [i]
the right-hand and left-hand hexagonal nipples connecting the units which
to make up a stack. There are three standard lengths of Vento heater-secti[o]

Fig. 62. Plan of the Assembly of a Vento Heater

as indicated in Table XLVIII, which also includes other data required by t[he]
designer.

Table XLVIII. Vento Hot-Blast Heater-Data

Length of section in inches	Heating-surface, regular sections, in square feet	Free area in square feet, per section, inches on centers			Ratio, squa[re] feet heating-surface to fre[e] area for 5 in[.] on centers
		$4\frac{5}{8}$	5	$5\frac{3}{4}$	
40	10.75	0.52	0.62	0.72	17.34
50	13.50	0.65	0.77	0.91	17.53
60	16.00	0.78	0.92	1.08	17.39

Selection of Hot-Blast Heaters. General Conditions. In select[ing]
the size of a heater for any particular service the choice is based on the f[inal]
temperature desired and the FREE AREA required for a certain allowable velo[city].
That is, for any specified initial and final temperature desired, and a cer[tain]
number of sections, a final temperature results when the velocity has been fi[xed]
in advance. Good practice limits the velocity to the values given by the f[ol-]
lowing tables. High velocities are objectionable in public-building work,

ount of the resulting noise. The resistance through the heater increases roportion to the square of the velocity, which adds to the power required nove the air as the velocity is increased, as will be noted later.

ating of Hot-Blast Heaters. The RATING of an assembled heater of sev- sections (pipe-coil type) or stacks (Vento type) is based on the TEMPERATURE- of the air passing over the heating-surface for certain velocities through the or unobstructed area of the heater-face. The VELOCITY is based on the me of air at an assumed temperature of 70° for convenience in rating.

t M = weight of air to be circulated through heater per hour;
.075 = density of air at 70°;
A = free area of heater in square feet;
V = velocity of air in feet per minute through free area based on 70° temperature.

en

$$A = M/(60 \times 0.075 \times V) = M/4.5V \text{ sq ft.}$$

e following tables will serve as guides in selecting the VELOCITY V and the ER OF SECTIONS OR STACKS for various purposes.

Table XLIX. Allowable Velocities of Air through Vento Heaters

Referred to a temperature of 70° F.

perature-Rise. The TEMPERATURE-RISE of the air passing through hot- eaters of various types has been well established by experiment, the manufacturers having published the results in the form of bulletins and es.

ple. It is required to determine the size of a Vento hot-blast heater to he necessary heat for a public building, the calculated heat-loss of which

is $H = 1\,420\,000$ Btu per hr for 70° inside and 0° outside temperature. Th temperature of the air entering the rooms, t_d, is to be approximately 120°. Th steam-pressure is 5-lb gauge. The temperature of the air entering the heat is 0°.

Solution. First determine from Table LI the number of stacks deep require for F.T. at 120° and entering air at 0°, using a velocity of 1000 ft per mi This condition calls for a 5-stack-deep heater. Then determine the weight the air to be circulated per hour.

$$M = H/[0.24(t_d - t)] = 1\,420\,000/[0.24(120 - 70)] = 118\,333 \text{ lb}$$

The free area required is

$$A = 118\,333/(4.5 \times 1\,000) = 25.1 \text{ sq ft}$$

Table LI. Final Temperatures and Condensations, Vento Heaters

Regular section, Standard spacing, 5-in center to center, of loops. Steam, 5-lb gaug C is the condensation in pounds per hour per square foot of heating-surface. F. is the final temperature of air leaving heater.

ing to Table XLVIII and choosing a 60-in length of units, 5 in on centers, und that the free area per section is 0.92 sq ft. The number of sections d across the face of the heater is

$$A/0.92, \text{ or } 25.1/0.92 = 27$$

ating-surface per section is 16 sq ft. The total heating-surface is there-

$$S = 5 \times 27 \times 16 = 2\,160 \text{ sq ft}$$

condensation per hour is

$$2\,160 \times 1.56 \text{ (Table LI)} = 3\,370 \text{ lb}$$

pplied by the boiler, or by exhaust-steam, at 5-lb pressure.

Design of Air-Ducts

ure-Loss. The frictional resistance of air flowing through smooth tal ducts, commonly termed PRESSURE-LOSS, measured in inches of r 70° air and for a length of duct equal to 100 ft, is given by the follow-ula:

$$h = 0.000136 \times (R/A) \times v^2$$

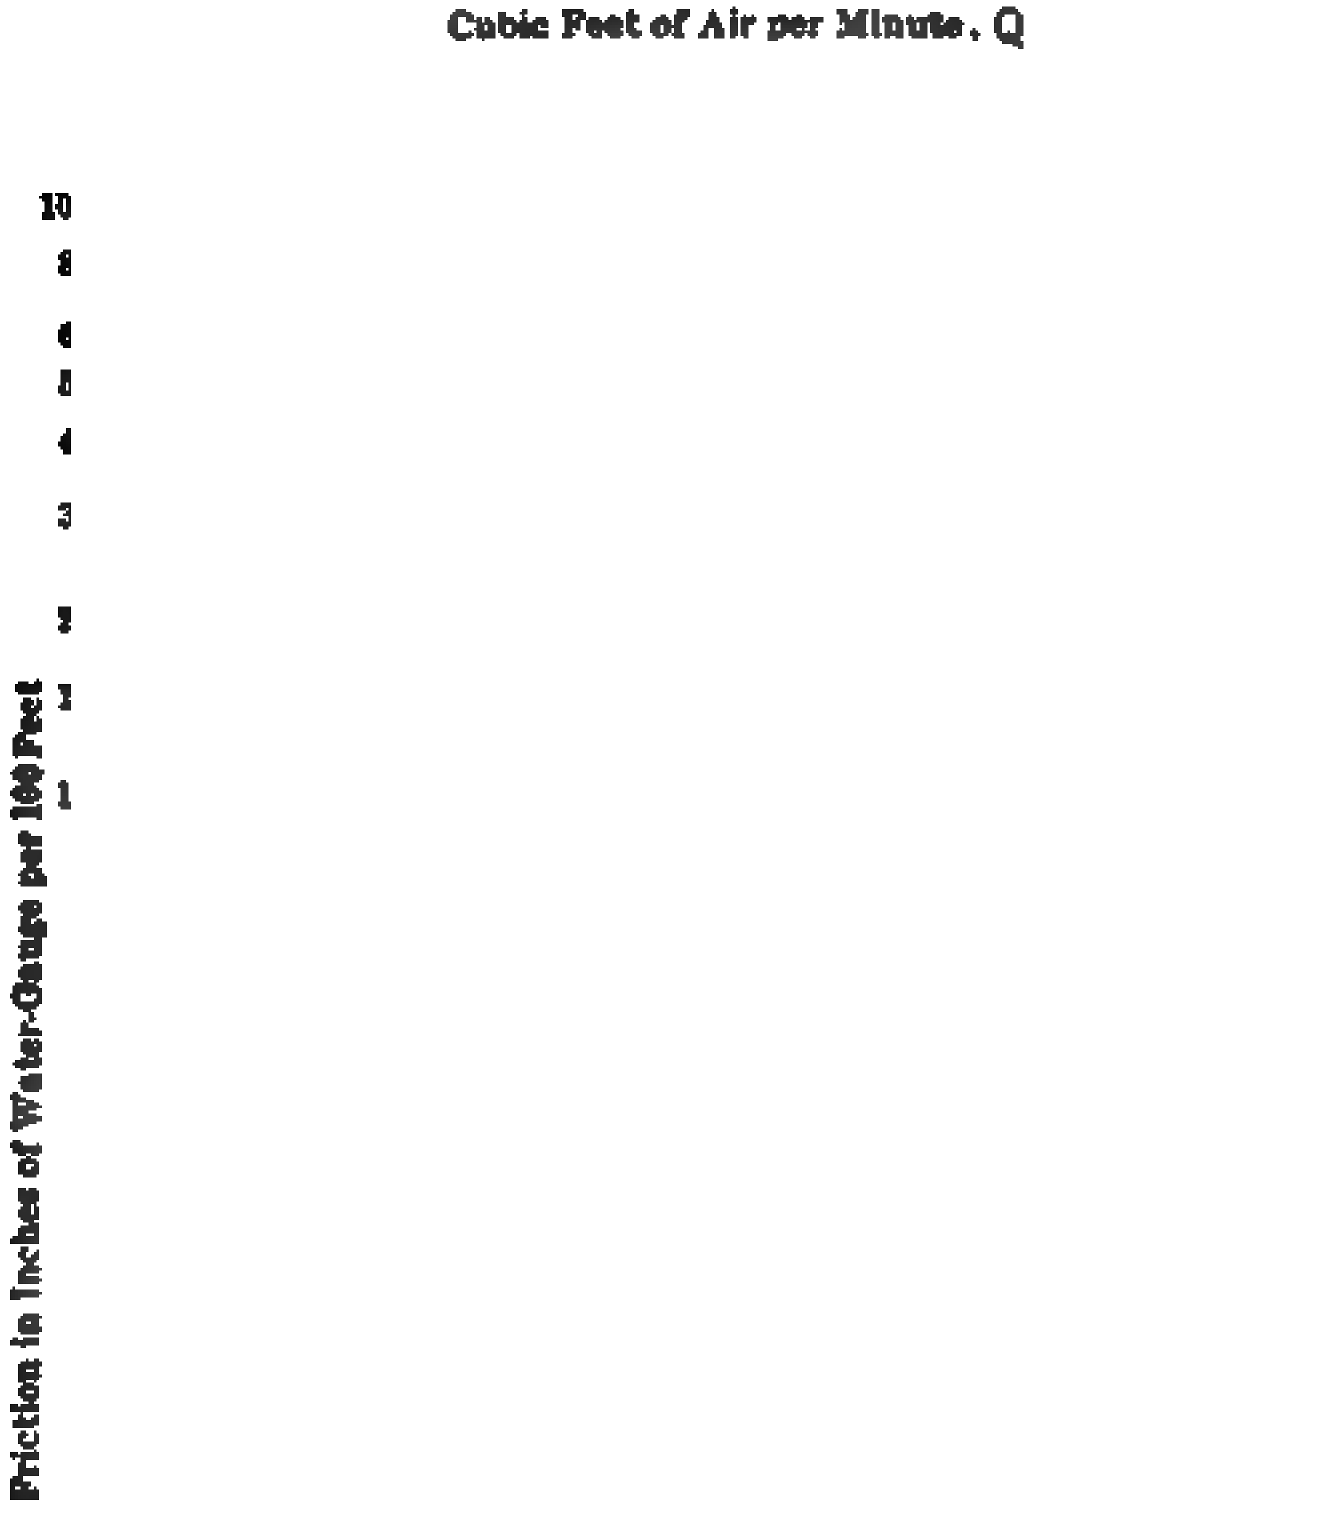
R is the perimeter of the duct in feet, *A* the area of duct in square e velocity of the air in feet per second, and *h* the pressure-loss

measured in inches of water-column. For round ducts the above form reduces to

$$h = 0.00055v^2/D$$

in which D is the diameter of the duct in feet.

The diagrams in Figs. 63 and 64 are based on this formula, from which t



METER OF A ROUND DUCT for various velocities, and the PRESSURE-LOSS or ISTANCE for various quantities of air flowing, may be found without solving above equation.

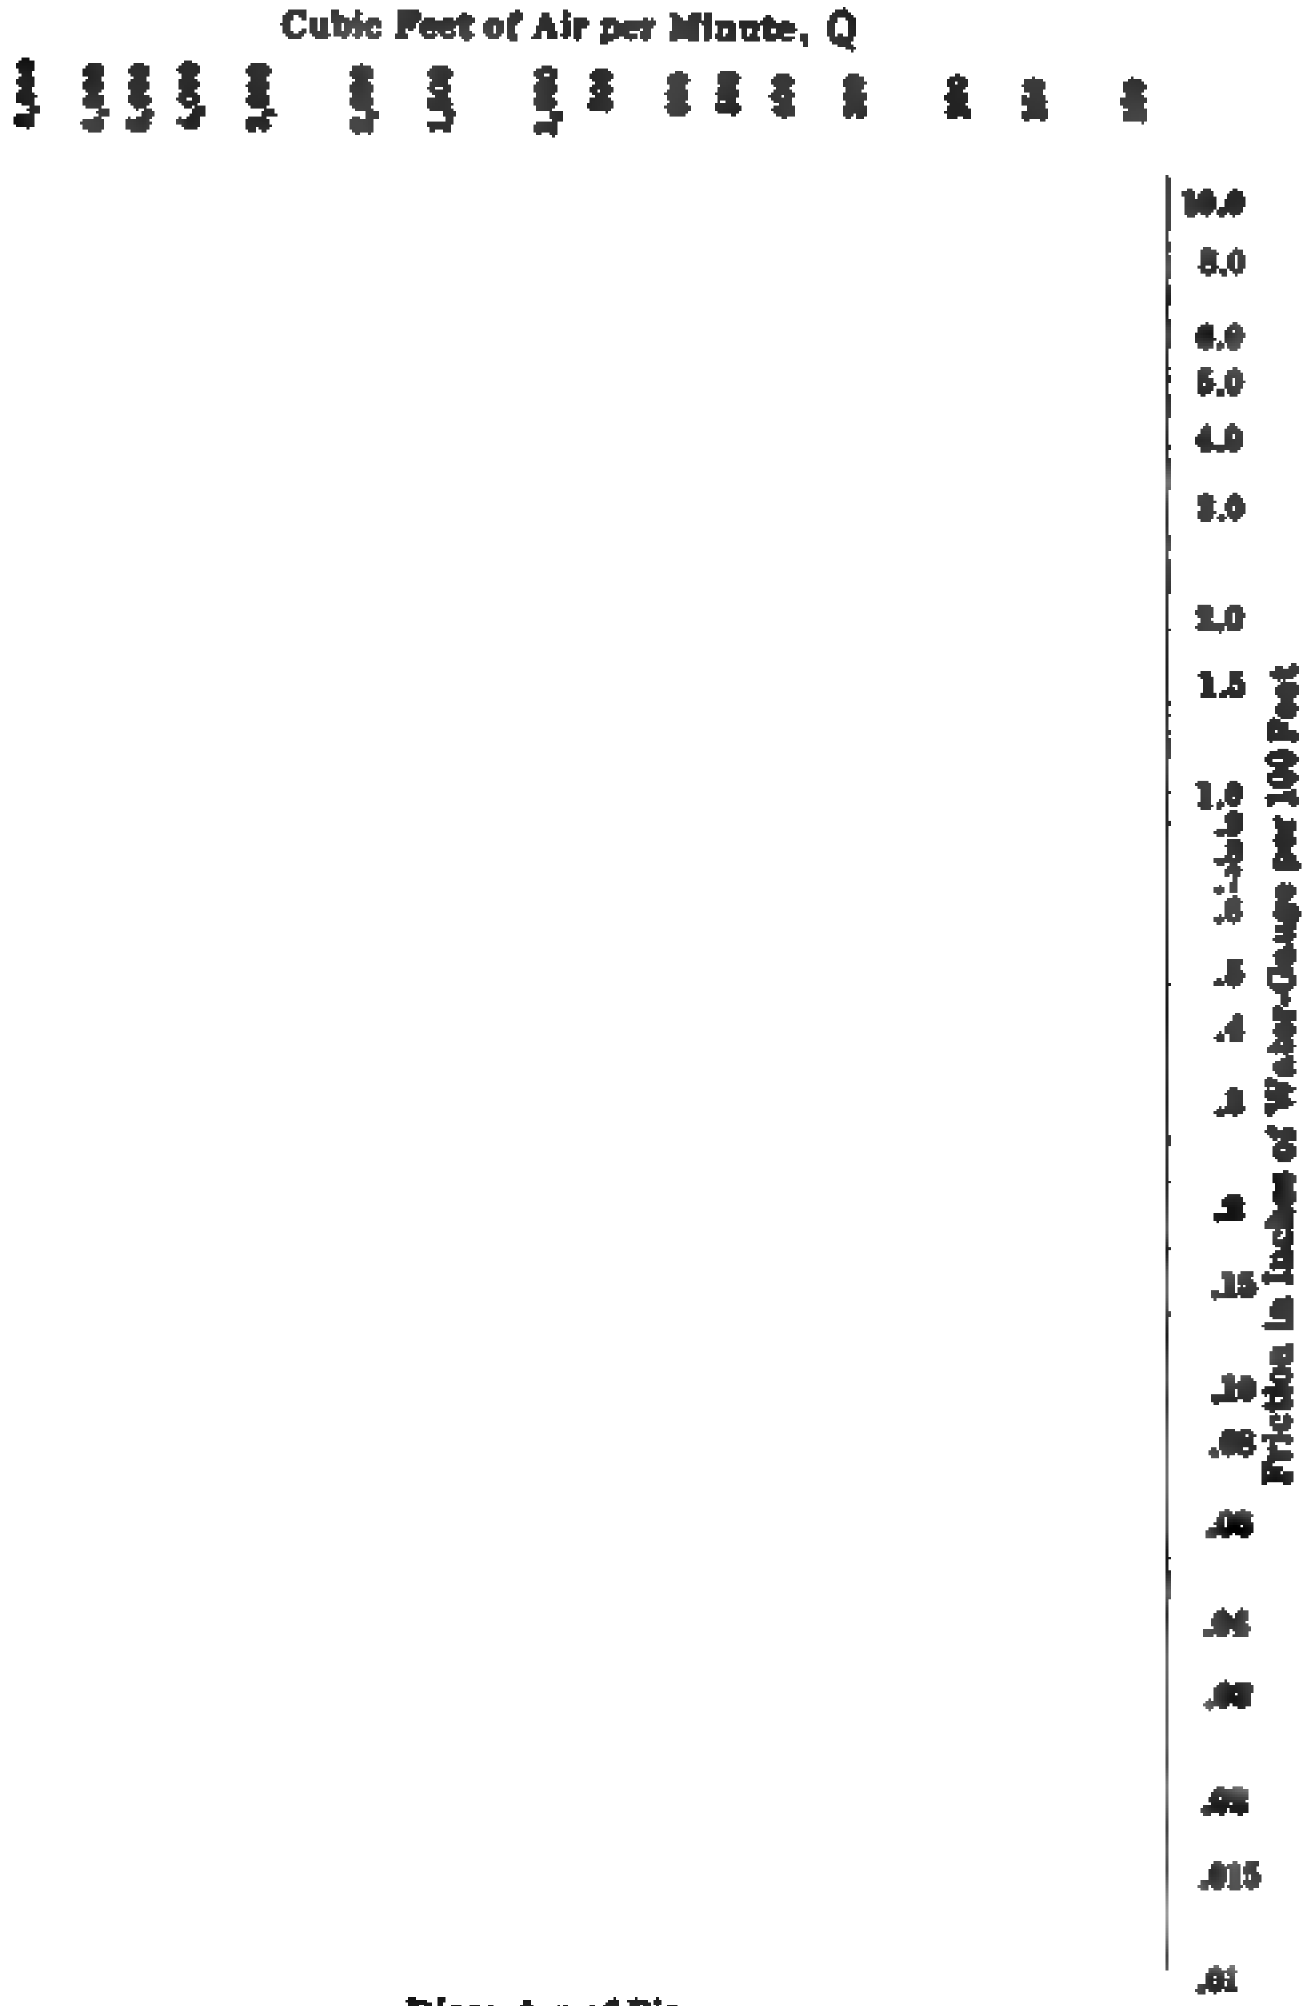


Fig. 64. Diagram of Friction-pressure Loss

ple. What should be the size of a round duct required to convey 1 500 air per minute with a velocity of 1 800 ft per min; and what is the pres- per 100 ft of duct.

Solution. Locate 1 500 on the upper side of the pipe-diagram in Fig. 64, an pass horizontally downward until the 1 800-ft-velocity diagonal line is inte sected. The duct which comes nearest to the required size has a diameter 12 in. At this intersection pass to the right side to the base-line and read 0.4 in water-pressure loss.

Allowable Velocity of Air in Ducts and Flues. In order to limit the resis ance or pressure-loss in the duct system the designer should, in general, keep t velocities within the limits stated in Table LII. In public-building work t air should be delivered to a room at a velocity that will insure its moveme to the desired points in the room without objectionable draft or noise in passi through the register-grills.

Table LII. Allowable Velocities in Hot-Blast Systems

Types of buildings	Allowable velocity in fee per minute
Public buildings	
Through free area of wall-registers	400– 500
Through free area of floor-registers	200– 300
Vertical flues to registers	600– 750
Connections to base of flues	800–1 000
Main horizontal distributing ducts	1 500–2 500
Manufacturing plants	
In plants where the occupation is more or less sedentary and the employe sits all day feeding automatic machinery:	
Main ducts	1 200–1 500
Branches	600– 900
In plants where the employe stands all day, as in machine-shops, foundries, etc.:	
Main ducts	1 500–2 400
Branches	900–1 500

The velocity through the fan-outlet, under the ordinary conditions that obtain in heati work, varies from 1 500 to 2 500 ft per min.

Example. What is the width of a rectangular duct 6 in high equivalent to the pressure-loss for a duct 12-in in diameter? **Solution.** 22 in.

Table LV. Friction Pressure-Loss of 90° Elbows

Radius of throat in diameters of pipe	1/4	1/3	3/4	1	1 1/4	1 1/2	2	3	4	5
Number of diameters of straight pipe of equivalent pressure-loss	67	30	16	10	7.5	6	4.3	4.8	5.2	5.8

Example. A duct 12 in in diameter and 120 ft long contains two 90° elbows. The ratio of the radius of throat to pipe-diameter is 3. The amount of air flowing is 1 500 cu ft per min and the velocity 1 800 ft per min.

Solution. The total equivalent length of duct is

$$120 + (2 \times 4.8) = 129.6 \text{ ft}$$

The pressure-loss, from the diagram of Fig. 64, is 0.48 in per 100 ft. The loss

$$0.48 \times (129.6/100) = 0.62 \text{ in of water}$$

The pressure-loss through register-grills may be taken at 0.023 in for a velocity of 400 ft per min through free area. The gross area of registers is twice the free area. The pressure-loss in standard air-washers for a velocity of 400 ft per min through the free area may be assumed to be 0.15 in of water. In the case of humidifiers, in which the spray is directed against the flow of air, a pressure-loss of 0.55 in of water may be assumed for preliminary estimates. The values assumed for this loss vary with different manufacturers. The pressure-loss through hot-blast heaters may be taken from Table LVI.

Table LVI. Friction of Air through Vento Heaters

Friction-loss, in inches of water, due to air passing through Vento stacks. Regular section. Standard 5-in spacing of loops. Air-temperature 70° F.

Velocity in feet per minute	One stack	Two stacks	Three stacks	Four stacks	Five stacks	Six stacks	Seven stacks

Effect of Temperature on Pressure-Losses. The preceding data on pressure-losses in ducts, registers and heaters are based on an air-temperature of 7[illegible]

other temperatures, the pressure-losses are to be multiplied by the ratio, ity of air at actual temperature to density at 70°. These ratios are given 'able LVII. For heaters use the average temperature of the air passing ugh the heater.

e LVII. Ratios of Density of Air at Actual Temperature to Density at 70° F.

emperature	Factor	Temperature	Factor
100	0.945	140	0.880
120	0.910	150	0.865
130	0.890	160	0.850

sign of Duct Systems. There are two schemes used in PROPORTIONING UCTS: (1) the velocity method, and (2) the method of equal friction pres- oss per foot of length. The first method involves the fixing of the veloci- see Table LII) in the various sections, and the gradual reduction of the ty from the beginning of duct to the point of discharge. In this case the re-loss is computed separately for each section having a different velocity ie various pressure-losses added together to obtain the total loss in pres- The second method is used principally in the design of duct systems for y-heating. The velocity in the outlet farthest from the fan is fixed and ea and diameter of this branch are determined by the volume of air to vered. The friction pressure-loss per 100 ft of a duct of this size is deter- by the diagrams in Figs. 63 and 64. The remainder of the main duct is roportioned for this same pressure-loss per 100 ft.

mple. The first method is illustrated in Fig. 65, showing a single-duct . The risers are figured for a velocity of 600 ft per min, or 10 ft per sec;

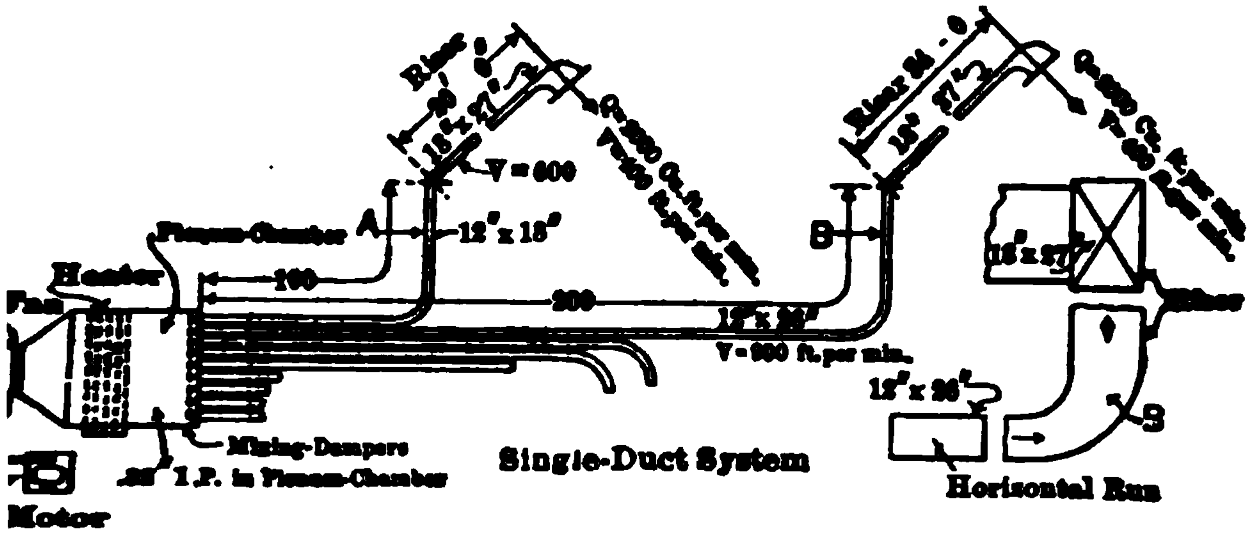

Fig. 65. Single-duct System

ft per min, or 6.6 ft per sec; through free area of register-grill. The in the longest main, *B*, is 900 ft per min, the volume of air to be delivered ft per min, and the temperature 120°.

n. The area of the riser required is

$$2\,000/600 = 3\tfrac{1}{3} \text{ sq ft, or } 480 \text{ sq in}$$

27-in riser, giving 486 sq in area, is used. The area of main, *B*, is

$$2\,000/900 = 2.22 \text{ sq ft, or } 320 \text{ sq in}$$

The size of the duct is 12 by 27 in. The diameter of a round duct for the sa
friction-loss for the riser, from Table LIV, is 24 in, and for the main, B, 19.5

Referring to the diagram in Fig. 64, the pressure-loss for the riser is 0.032
per 100 ft. For the main the pressure-loss is 0.09 in per 100 ft. The main h
one elbow and the riser one elbow, and the ratio of radius at throat to diame

Fig. 66. Part of Basement-layout for a Single-duct System for a School-building

will be assumed to be 3, in both cases. The equivalent length of main, B
therefore

$$200 + (4.8 \times 20/12) = 208 \text{ ft}$$

and the pressure-loss is

$$0.09 \times (208/100) = 0.187 \text{ in}$$

The equivalent length of riser is

$$34 + (4.8 \times 24/12) = 44 \text{ ft}$$

and the pressure-loss is

$$0.032 \times (44/100) = 0.014 \text{ in}$$

'he pressure-loss through the register-grill is 0.023 in. The total resistance he duct system is therefore

$$0.0187 + 0.014 + 0.023 = 0.224 \text{ in}$$

ssuming that a five-section Vento heater is employed, with a velocity (fig-l through free area) of 1 200 ft per min, the pressure-loss through the heater .376 in (Table LVI). The total resistance against which the fan must ate is

$$0.224 \text{ in} + 0.376 \text{ in} = 0.60 \text{ in}$$

d on 70° air. Assuming the temperature of the air to be 120°, the resist-is

$$0.60 \times 0.91 \text{ (Table LVII)} = 0.55 \text{ in}$$

e second method of duct-design is illustrated by the example given under ication of Hot-Blast Heating-Data, page 1342.

Ventilating Fans

el-Plate Fan. The standard type of fan that has been used for a number of in hot-blast work is known as the STEEL-PLATE FAN, the construction of the being shown in Fig. 67. As the name implies, the wheel and casing of this re constructed of steel plate ght structural sections, the having eight to twelve , straight or slightly curved periphery, and in a direc-opposite to the rotation. late fans are designated by r, this number being the imate height of the fan-in inches.

ibladed Fan. A new type , known as the SIROCCO or TURBINE-TYPE IMPEL-g. 68, has recently entered d of heating and ventilat-l on account of its higher y, quieter running, and ly smaller size for the same than the steel-plate fan, dly supplanting the latter. her efficiency is accounted for by the material reduction of the air-e or pressure-head loss by friction through the fan, due to the shorter nd the larger inlet, which is of practically the same diameter as the self. This fan deserves more than passing mention as it represents the greatest single improvement ever made in the design of a centrif-

Fig. 67. Standard Steel-plate Fan-wheel

g of Fans. The volume of air at 70° which a fan will deliver (cubic feet te) varies with the resistance against which it operates. In order to fan from Table LIX, the resistance (static pressure) must first be ed by the duct-design, and after the size of the heater has been chosen esistance determined. The speed and brake horse-power required to

drive the fan are also stated in the tables. The temperature of the air hand by the fan with DRAW-THROUGH apparatus is higher than 70°, except for a f which is connected ahead of a tempering-coil, usually a two-section-deep heat The tabulated speed, volume and brake horse-power to maintain the press must be multiplied by the fact given in Table LVIII for temperatu other than 70°. The above fact in this table are the square roots the ratios of the density of the ai 70° F. to its density at the tempe ture stated.

Fig. 68. Sirocco Wheel or Turbine-type Impeller

Table LVIII. Factors for Speed, V ume and Brake Horse-Power

Temperature in degrees Fahrenheit	Factors
0	0.932
100	1.028
120	1.046
130	1 055
140	1.064
150	1.073

Application of Hot-Blast Heating-Data

The Application of the Foregoing Data on hot-blast heating to a facto building follows (see Fig. 69). The calculated heat-loss is 1 423 920 Btu per

Conditions. Air recirculated and inside temperature maintained at 6 Velocity of air through heater, from 1 000 to 1 200 ft per min. Velocity of at last outlet in duct system, 1 275 ft per min. Temperature of air deliv by heater, 145°.

Weight of Air to be Circulated per Minute. This is

$$1\,423\,920/[0.24(145 - 60)160] = 1\,163 \text{ lb}$$

Size of Heater. This condition, 60° initial and 145° final tempera requires a heater five stacks deep (Table LI), and a velocity of 1 000 ft per through free area at a temperature of 70°. The volume of air per m measured at 70°, to be handled by the heater and fan is

$$1\,163/0.075 = 15\,506 \text{ cu ft}$$

The FREE AREA required is:

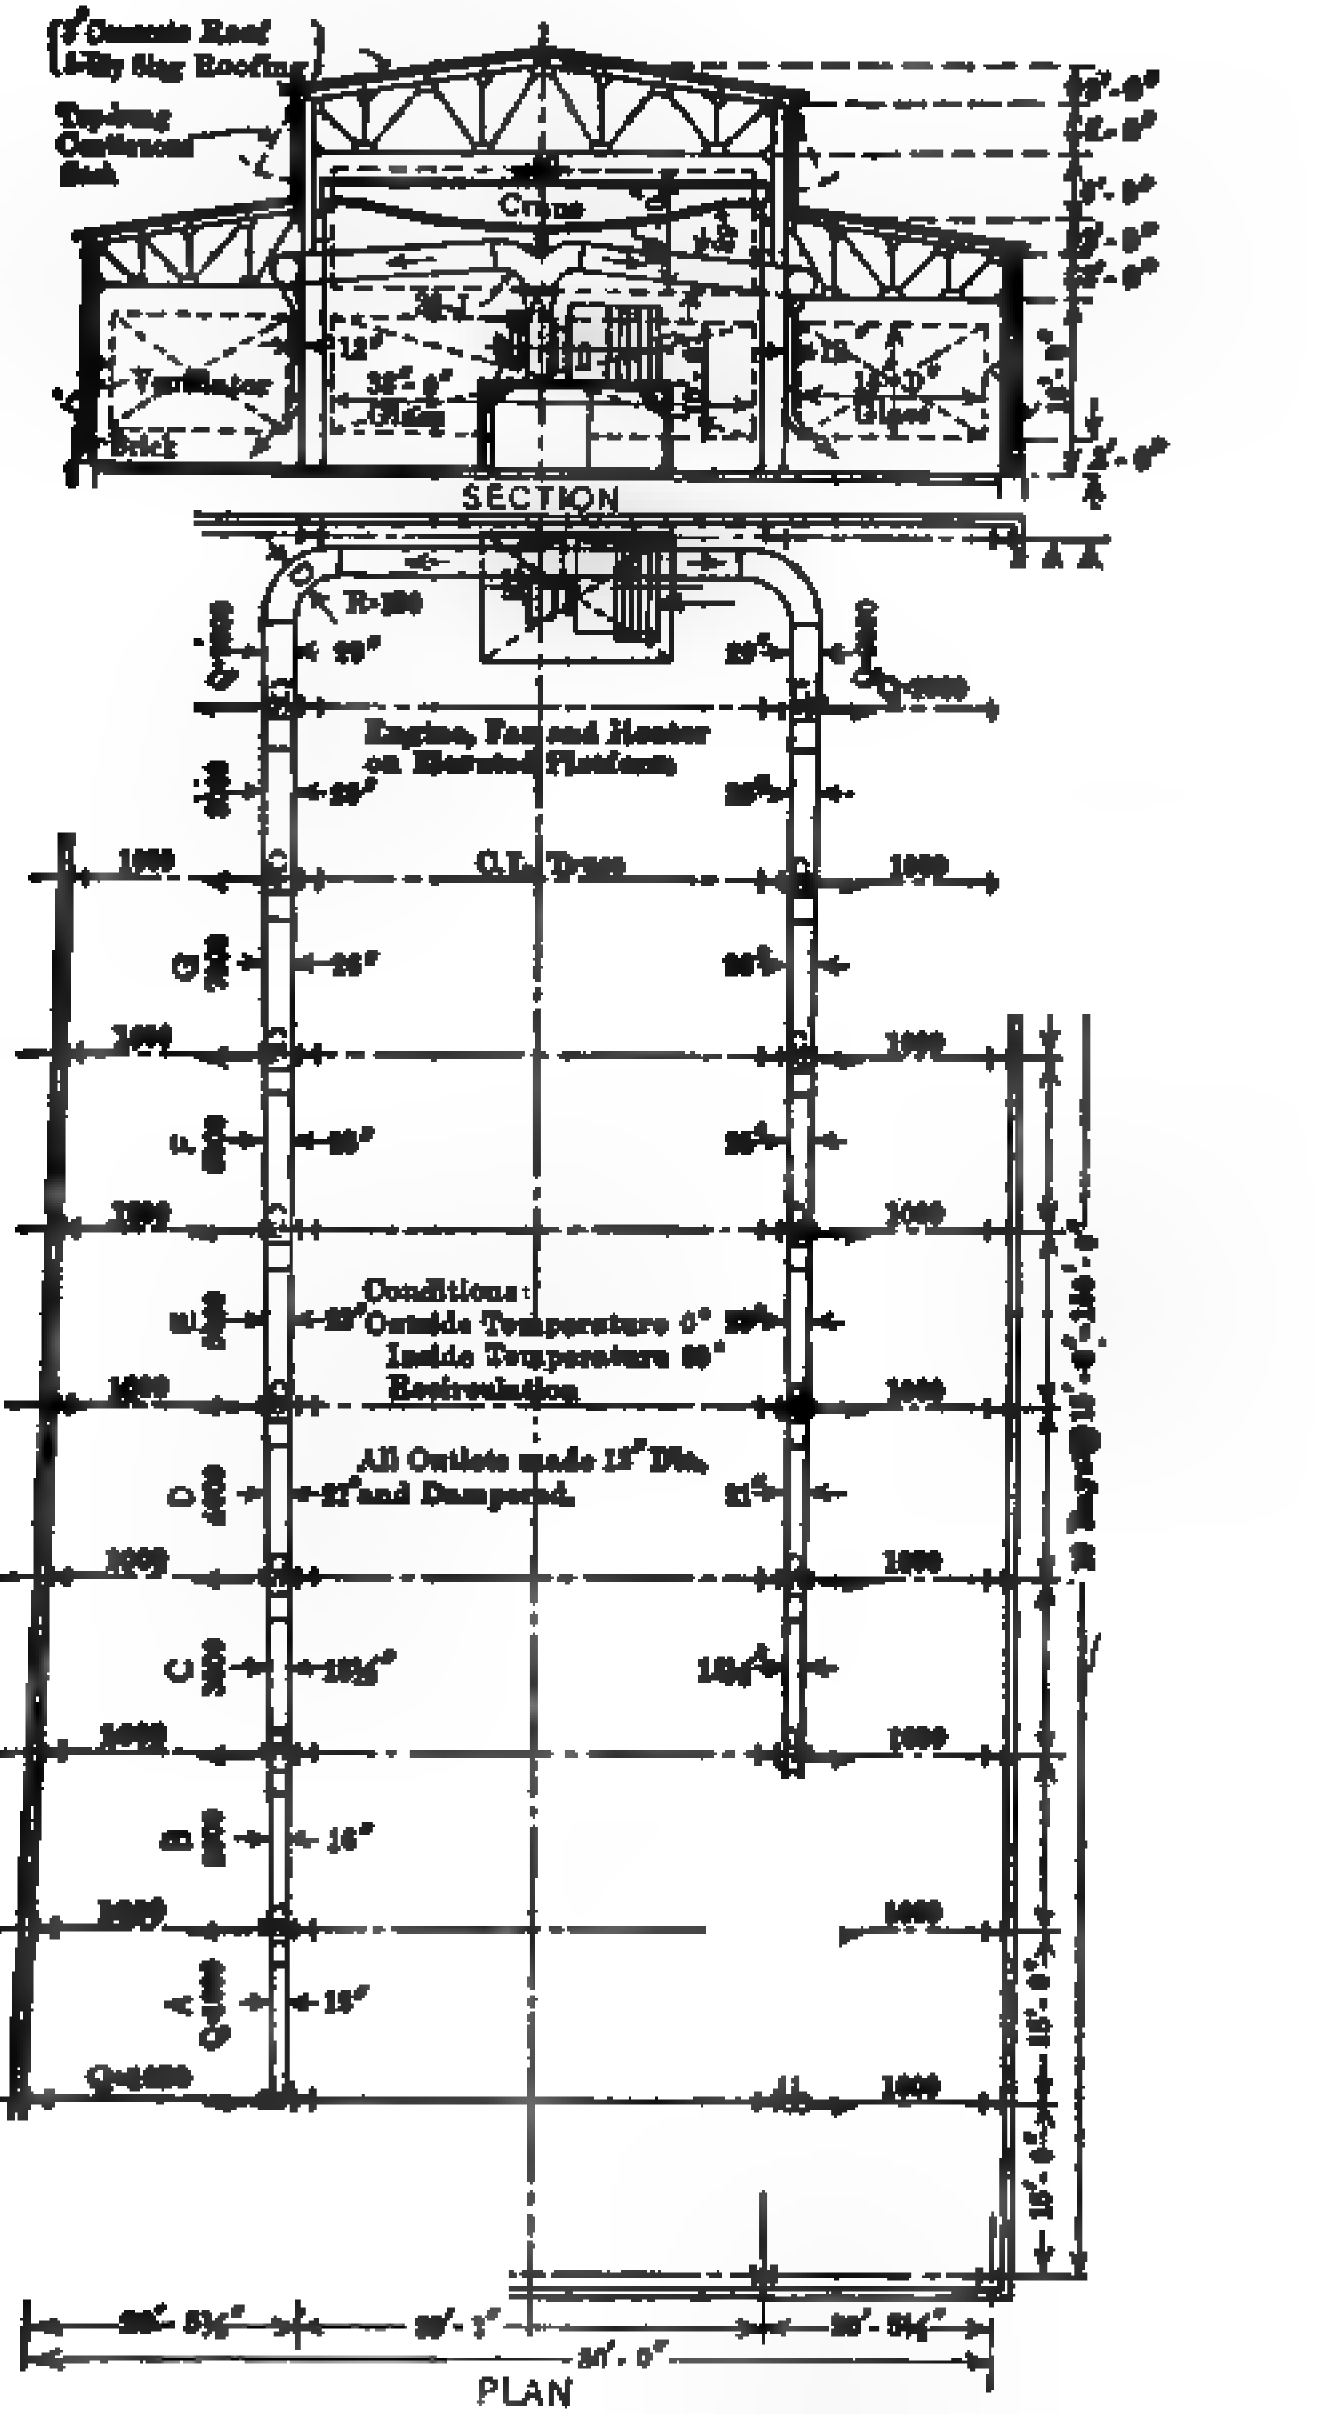
$$15\,506/1\,000 = 15.5 \text{ sq ft}$$

Assuming a 60-in length of section with loops 5 in on centers, the free are section is 0.92 sq ft (Table XLVIII). The number of sections per stack is

$$15.5/0.92 = 17$$

The total number of sections required is

$$5 \times 17 = 85$$



Hot-blast Heating for a Factory-building. (See Example for Computations)

Double-inlet fans have approximately double the capacities of single-inlet fans and require for their operation, under the same conditions, approximately twice the power. The "per-cent opening" refers to the opening used for the rating given from the test-data.

* C. F. M. denotes cubic feet per minute, R. P. M., revolutions per minute and B. H. P., brake horse power.

The total heating-surface is

$$85 \times 16 = 1\,360 \text{ sq ft}$$

Weight of Steam or Condensation per Hour. This is

$$1\,360 \times 1.09 \text{ (Table LI)} = 1\,482 \text{ lb}$$

The equivalent amount of direct radiation is

$$1\,482/0.25 = 5\,929 \text{ sq ft}$$

Design of Duct System. The round ducts will be designed for equal-frictio pressure-loss per foot of length. The final velocity at the last or most remot outlet from fan will be taken at 1275 ft per min. The friction pressure-loss fo this velocity, as read from the diagram in Fig. 64, is 0.25 in of water per 100 of length. There are to be eighteen outlets. The total volume of air to be di charged, measured at 145° F., is

$$1\,163/0.065 = 18\,000 \text{ cu ft per min}$$

or

$$18\,000/18 = 1\,000 \text{ cu ft per min per outlet}$$

The cross-sectional area of the outlet or last section is 1 000/1 275 sq ft, co responding to a circular section with a diameter of 12 in. The branch-outle may all be made the same size and provided with dampers to adjust or equali the flow. The friction pressure-loss in the duct system is therefore

$$(212/100) \times 0.25 = 0.53 \text{ in of water}$$

The size of each section of duct is determined by locating the quantity of a at the right of the diagram and passing horizontally to the intersection with th 0.25-in pressure-loss line.

Table LX. Data for Design of Ducts in Fig. [illegible]

Section	Quantity of air in cubic feet per minute 145° F.	Duct-diameter in inches	Velocity in feet per minute	Measured length plus allowance for ells, in feet

H	8 000	28	....	15
I	9 000	29	....	35 + [2.4(6 + 10)] = 7
J	18 000	38	2 285	....
				Total length = 212

Selection of Fan for Draw-Through Arrangement. The static press rating required, referred to a temperature of 70°, is:

Pressure-loss in heater (data from Table LVI) = 0.26 in
Pressure-loss in duct (data from chart, Fig. 64) = 0.53 in

Total = 0.79 in

The actual pressure-loss will be somewhat less, owing to the fact that the air-
mperature is higher (145° F.) and the density less than for air at 70° F. The
tual estimated pressure-loss is therefore assumed to be ¾ in.

The volume of air the fan must handle in this example is 18 000 cu ft per min,
easured at 145° F. As stated under Rating of Fans, to maintain a constant
essure the tabulated speed, volume and horse-power must be multiplied by
e square root of the ratio of densities, or

$$\sqrt{0.075/0.066} = 1.07 \text{ (nearly) (Table II)}$$

We therefore select from Table LIX a fan having a capacity, measured at
' F., equal to

$$18\,000/1.07 = 16\,822 \text{ cu ft per min (approximately 17 000)}$$

en operating with a static pressure of ¾ in. A No. 8 Sirocco fan fulfills this
uirement. The tabulated speed and horse-power when multiplied by the
or 1.07 gives

$$196 \times 1.07 = 210 \text{ R.P.M.}$$

$$3.76 \times 1.07 = 4.02 \text{ brake horse-power}$$

election of Fan for Blow-Through Arrangement. In this case the
may be called upon to handle air at a temperature of 0° F., or lower. Assum-
he same weight of air, or 70 000 lb per hr, to be handled by the fan at a static-
sure of ¾ in, the volume at 0° is

$$70\,000/(0.086 \times 60) = 13\,566 \text{ cu ft per min}$$

rring to Table LVIII, the ratio between the speed, volume and power neces-
to produce the same pressure for air at 0° and air at 70°, is found to be
. We therefore choose a fan with a capacity of

$$13\,566/0.932 = 14\,557 \text{ cu ft of air at } 70°$$

with a static pressure of ¾ in.

m-Engine. When high-pressure steam is available an automatic high-
engine is frequently employed for fan-driving, and the exhaust from the
e is used in the first section of the heater.

ection of Motor for Fan-Driving. It is considered good practice to add
10 to 15% to the brake horse-power, as determined from the fan-tables,
e rating of the motor, to allow for a possible overload due to the fact that
n may not be operated under exactly the same conditions as to pressure
eed as those under which it was originally rated. For the preceding exam-
raw-Through Arrangement) a 5-horse-power motor would be selected.

litional Heating Requirement. It is frequently desirable to proportion
ating-apparatus large enough so that the fan may be shut down at night
arted up about two hours before the shop or factory is opened in the
g. In this event it may be safely assumed that the temperature of the
the building will not be below 30° F. when the fan is started, and that
is all recirculated. The fan and heater must be of sufficient capacity
e care of the heat-loss from the building, including the infiltration, and
tion to warm up the contained air from 30° to 60° in two hours. Assum-
same data as given in the preceding example, the additional heat re-
will be, if the cubic contents of the building are 328 000 cu ft,

$$(328\,000 \times 0.08 \times 0.24 \times 30)/2 = 94\,464 \text{ Btu per hr}$$

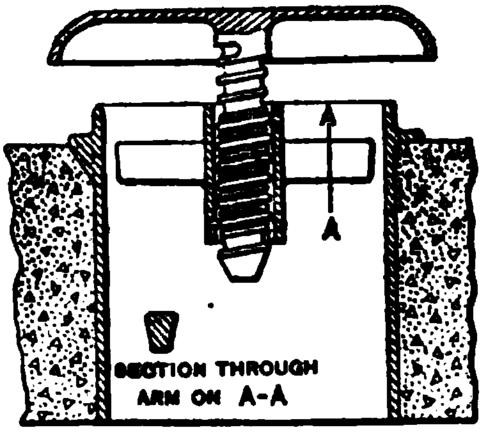
This amounts to an increase of approximately 7% in the heating requirements as previously calculated, and is readily provided for by increasing the steam pressure carried in the heater to approximately 10-lb gauge. Catalogues, bulletins, etc., on the subject of hot-blast heating, air-washing and humidification may be obtained from the American Blower Company, the B. F. Sturtevant Company, the Buffalo Forge Company, and the Carrier Air Conditioning Company.

Ventilation

Natural and Mechanical Ventilation. Ventilation, whether NATURAL or MECHANICAL, consists in the displacement of vitiated air from an apartment and

s replacement by fresh air. To state that the air in an apartment is renewed ny given number of times per hour is not strictly accurate, as a positive change oes not actually occur; the incoming air mixes with and dilutes the foul air to a oint suitable for healthful respiration. In NATURAL-VENTILATION systems the iovement of the air in flues, ducts, etc., is induced solely by the thermal head roduced by the difference between the density of the column of air in the ucts and that of the outside atmosphere; the higher the temperature in the ucts the more powerful the draft. The direction and velocity of the wind aterially affect the natural ventilation, retarding or accelerating the moveent of the air through ducts and flues, according to the exposure of the building id the position of inlets and outlets. In MECHANICAL VENTILATION the moveent of air is maintained by means of various types of fans, driven by a steamgine, electric motor, or other prime mover. With fans of known efficiencies e results can be accurately estimated. The principal advantages of the use mechanical systems of heating and ventilation have already been stated der Hot-Blast Heating.

Systems of Ventilation. Ventilation systems are also broadly divided into o general classes known as the UPWARD SYSTEM and the DOWNWARD SYSTEM. e UPWARD SYSTEM (Fig. 70) is generally used for audience-rooms where there is ong natural tendency for the heat given off by the large number of occupants to e and take with it the vitiation-products due to respiration. The AIR IS SUPED NEAR THE FLOOR-LINE through mushroom ventilators in the floor, or ough the hollow pedestals of the chairs themselves, or through low registers. e VITIATED-AIR OUTLETS ARE IN OR NEAR THE CEILING. This system makes it her difficult to heat the room in advance of the arrival of the audience as the lets allow the warmed air to escape almost rapidly as it can be introduced. The VNWARD SYSTEM is very generally used chool-rooms, hospitals, institutions, etc. occupants are not as closely placed as he former case, and a more even distrion of air and more uniform heating can ecured when the AIR IS SUPPLIED EIGHT T OR MORE ABOVE THE FLOOR, and the ATED AIR REMOVED AT OR NEAR THE OR-LINE. On account of the elevation e inlets above the heads of the occupants e is little liability of drafts, and if the ts are on the same side wall as the inthere is very little opportunity for -circuiting between inlet and outlet, the incoming air must flow out across oom to the cold outside wall before it cool and drop to the floor-level. It is, ver, necessary in the downward system, vercome the natural tendency of the d air from the bodies of the occupants to rise and oppose the uniform ward tendency of the incoming fresh air. The selection of either system depend entirely on the conditions to be met. These have been outlined above paragraphs.



SIZES OF "ABC" MUSHROOM VENTILATOR.

Size.	Approximate Inside Diameter.	Approximate Weight
4	4¼	6 lb.
5	5¼	10 lb.
6	6¼	15 lb.

Fig. 71. Section through A B C Mushroom Ventilator

stribution of the Air. In general, it should be observed that whether rd or downward ventilation is employed there should always be a definite n of vitiated-air removal, designed to provide for uniform distribution and

prevent short-circuiting between inlets and outlets. A practically complete diffusion can only be attained when inlet and outlet are placed in the same inside wall, with the former at least from 7 to 8 ft above the latter. MULTIPLE

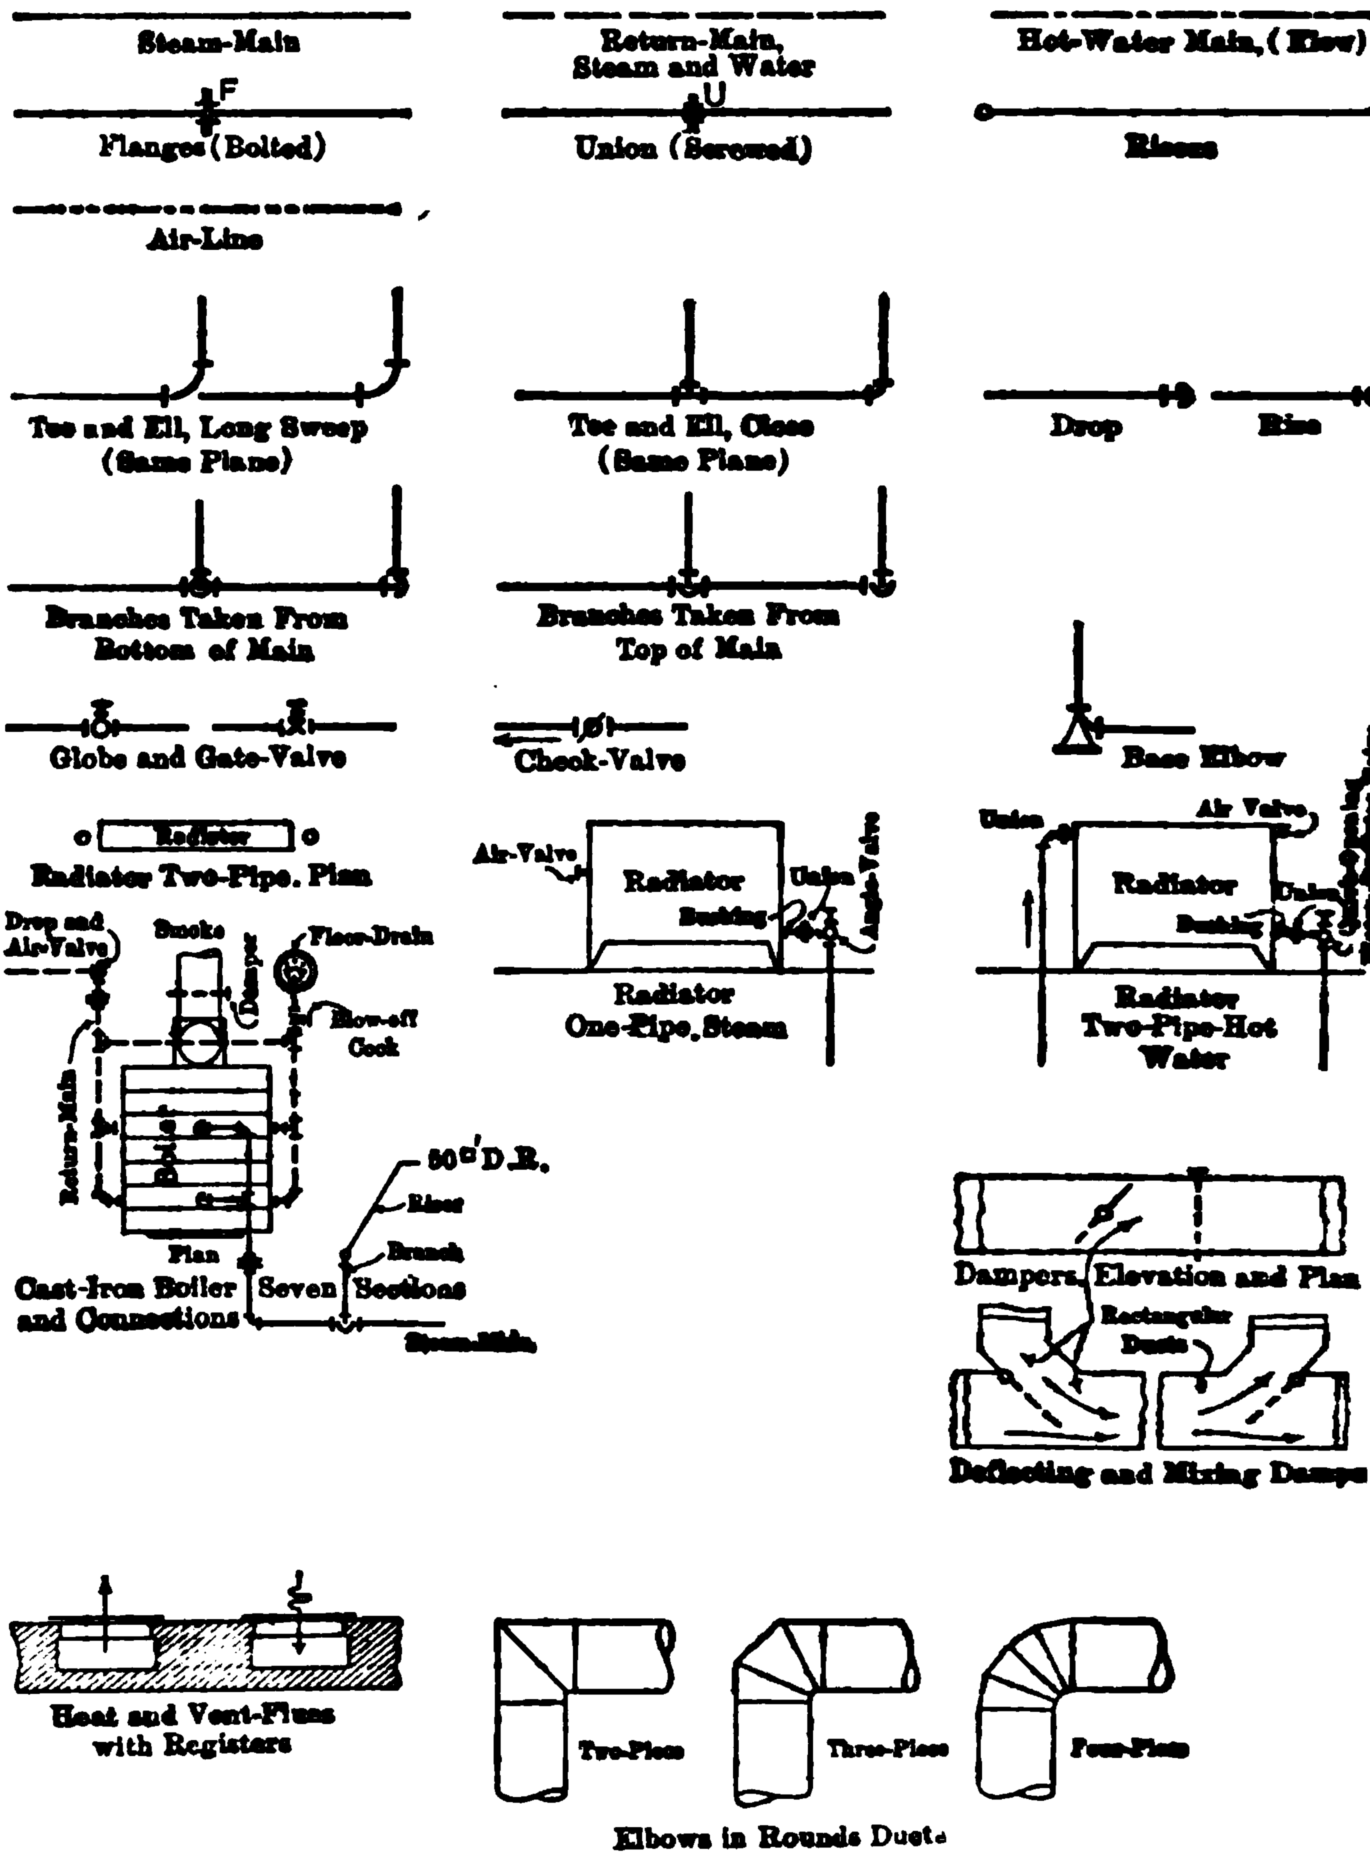


Fig. 72. Heating and Ventilating Symbols

INLETS and MUSHROOM VENTILATORS, in order to secure a better mechanical distribution of the air, are being made use of in many systems of upward ventilation for audience-rooms with fixed seats. In this case a false floor or PLENUM CHAMBER must be constructed just below the main floor through which the air

to be supplied. Mushroom ventilator-heads (Fig. 71) are then located under ery second or third seat and adjusted to give a uniform discharge of tempered r over the entire seating-area. These heads are either mounted on an ad-

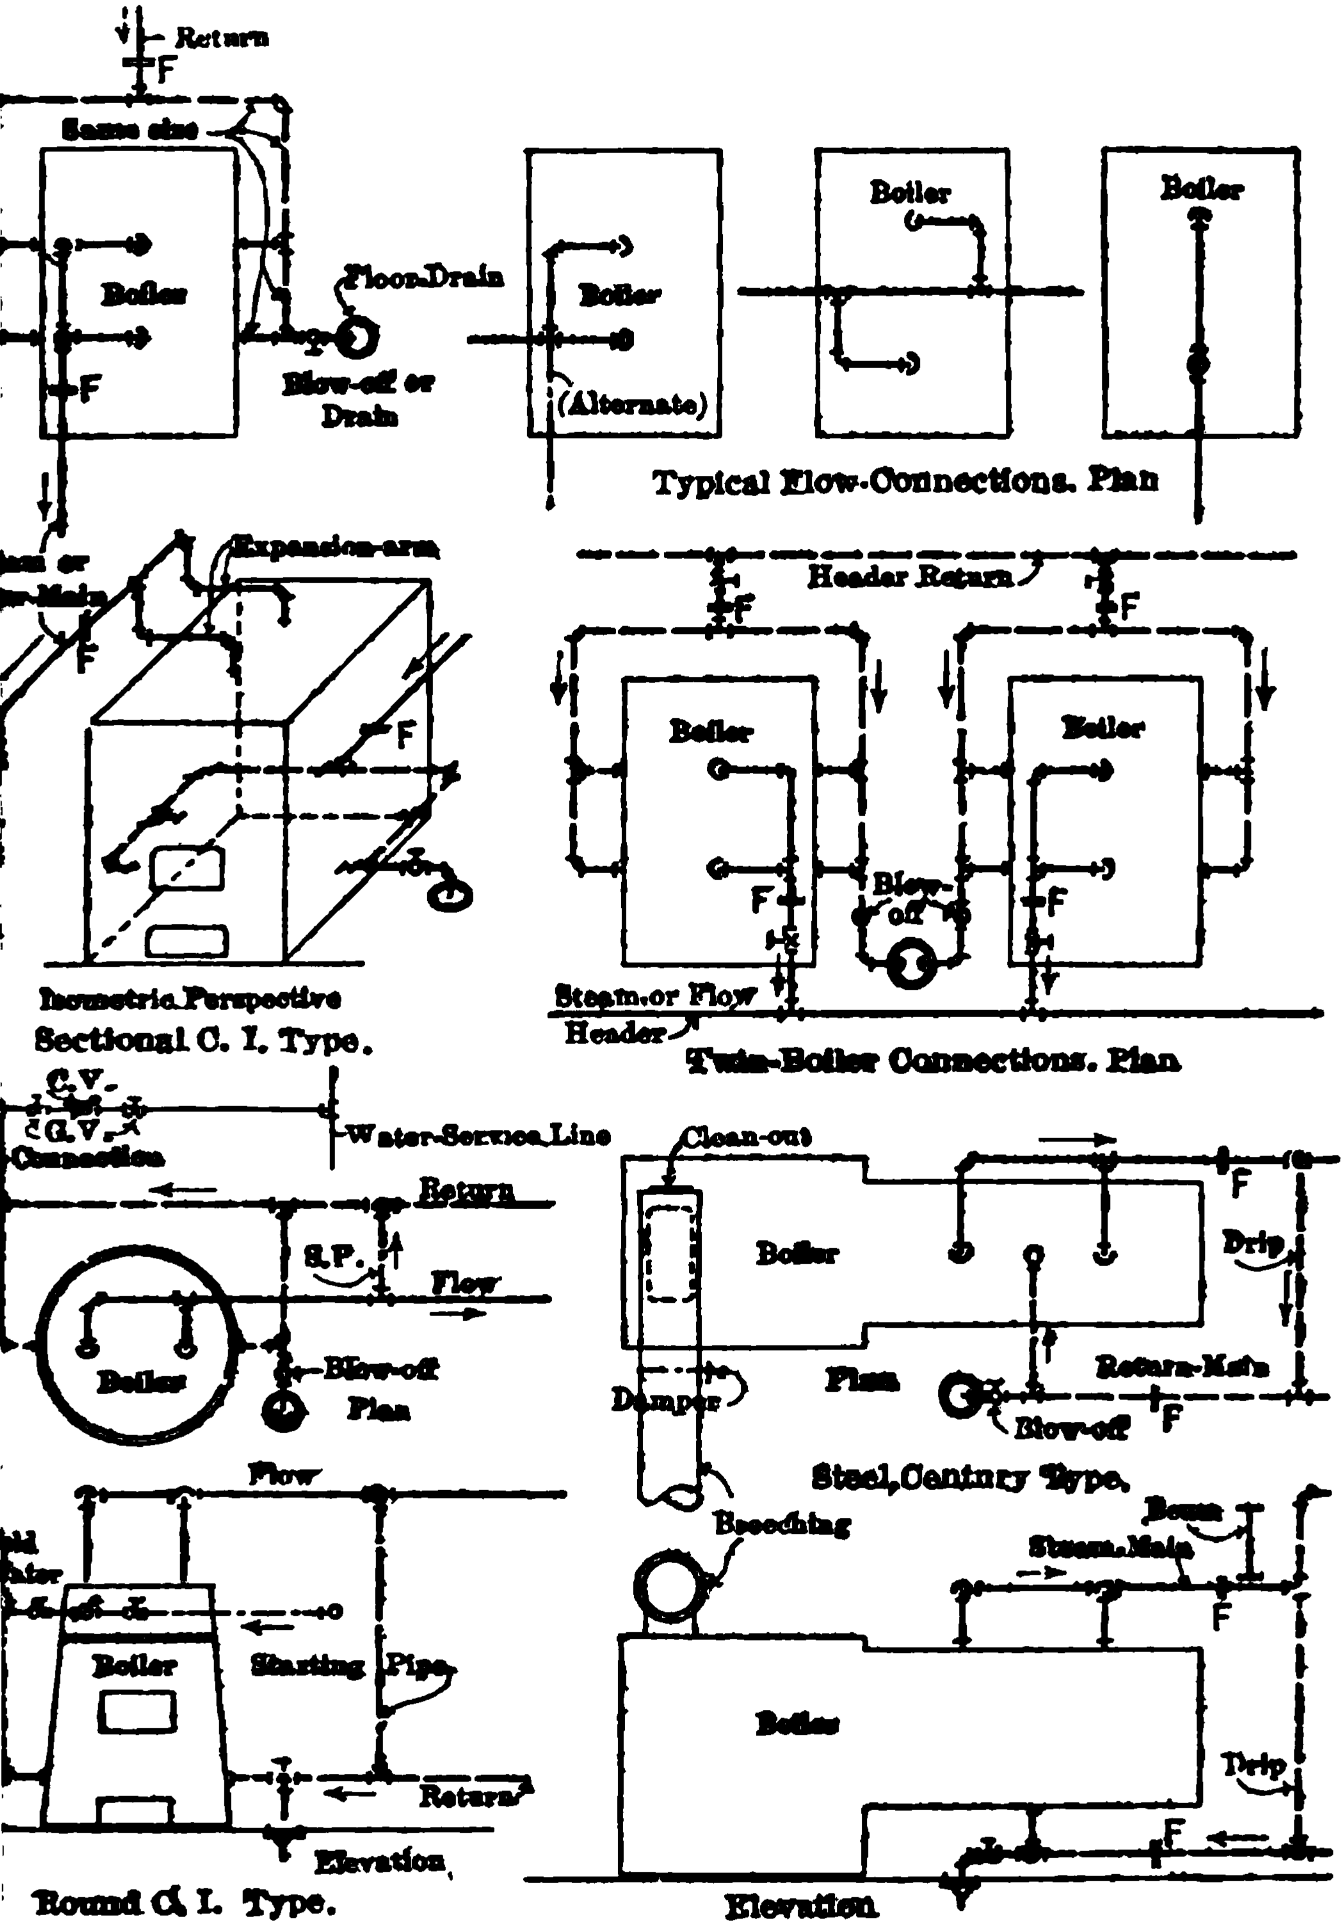

Fig. 73. Heating-boiler Connections

stable spindle (Fig. 70), which is supported centrally in the cast-iron floor-eve or flange, or else they have a non-adjustable spindle similarly supported, d are equipped with a control-damper. In either case the adjustable head or

damper must be locked positively in the finally adjusted position. In the c of concrete floors it is very desirable to use a cast-iron sleeve and flange (F 70) rather than a galvanized sleeve and cast-iron flange.

The Effect of Vitiated Air. The amount of CARBON DIOXIDE present vitiated air has been, until recently, quite generally understood to be the elem of danger that should be kept within safe limits. Dr. Ira Remsen has pointed that the presence of carbon dioxide in itself is not dangerous to health exc that it reduces the supply of oxygen by displacing it. Carbon dioxide is poisonous, but the ORGANIC IMPURITIES that are exhaled at the same time w other gases that are given off may prove a menace to health. The ill effects breathing air in a poorly ventilated room are due to the small quantities decomposing organic matter and unhealthful gases. The carbon dioxide g erated by the lungs and given off at the same time as the other impurities ser more or less as an indicator of the presence of the real danger. Any loweri of the oxygen-supply that is actually required for the proper and necess transformation of the potential heat-value of the food into the physical a nervous energy required to keep the human machine running, and to read supply the additional demand made upon that machine to perform exter work, means that industrial workers who perform their duties in a vitia atmosphere do so at the expense of a lowered vitality, and are naturally l productive. Satisfactory ventilation consists not only in constantly supplyi in a pure condition, fresh air FREE FROM DUST AND OTHER IMPURITIES, at t proper temperature and WITH THE PROPER AMOUNT OF MOISTURE PRESENT, b also in efficiently removing the vitiated air. This cannot be positively acco plished during the heating-season by simply opening the doors and windo Some mechanical means must be employed. Many physicians, however, not believe in MECHANICAL VENTILATION for hospitals, and advocate ventilat by the OPEN-WINDOW METHOD; and many hospitals are now constructed with any provision for mechanical ventilation except for the toilets and operati rooms for which exhaust-fans are provided.

Relation between Humidity and Temperature. The proper and health RELATIVE HUMIDITY OF THE AIR in buildings has only in recent years been gi the thought and attention it rightfully deserves. Heated or warmed whether purposely introduced into a building for warming, or naturally enter by infiltration, on being expanded by heat, has its percentage of moisture or re tive humidity lowered, and consequently its CAPACITY FOR ABSORBING MOIST greatly increased. There is, therefore, experienced the sensation due to so-ca DRY HEAT. This causes an excessive and unnatural evaporation of moist from the skin and from the membranes of the respiratory organs. Evaporat takes place by the direct application of heat and is essentially a refrigerating cooling process. The abstraction of heat from the body for this purpose, n urally tends to lower the surface-temperature, and one feels several degr cooler than the temperature recorded by the thermometer in the room. H. M. Smith's many observations and experiments upon the sensations produ by DIFFERENT PERCENTAGES OF SATURATION, led him to make the following st ment: "It may be accepted as a cardinal rule that if a room is at 68° and is warm enough for any healthy person, it is because the RELATIVE HUMIDIT too low." A STANDARD RELATIVE HUMIDITY may be obtained when mechan ventilation is used by the addition of a HUMIDIFIER to the system. The sub of AIR-CONDITIONING is fully treated in Heating and Ventilating, Vol. I, Harding and Willard.

Requirements for Good Ventilation. There is quite a diversity of opi among various authorities as to what constitutes GOOD VENTILATION in m

tances. The following data by G. D. Small represent good practice in this pect:

Types of Buildings. Air-Changes to be Allowed

FICE-BUILDINGS	Portions above grade	One change per hour.
	Basement, general	Four changes per hour.
	Mechanical plant	Ten changes per hour.

CTORY-BUILDINGS which have no mechanical or natural ventilation, one change per hour. For factories in which large doors from the outside are frequently opened, about four air-changes per hour.

SIDENCES which have loose windows, two changes per hour.

URCHES. Four changes per hour, except small rooms, which should have five or six changes per hour. These data for churches contemplate mechanical ventilation. The majority of public buildings and many of the factories require ventilation or the fan system of heating.

The Usual Requirements for Air Supplied per Person are as Follows

PITALS	Ordinary	from 35 to 40 cu ft per min
	Epidemic	80 cu ft per min

	Air-change
Detention-rooms	6 min
Toilet-rooms	6 min
Bath-rooms and duty-rooms	8 min
Kitchens	3 min
Serving-rooms	10 min
Fumigating-rooms	10 min

KSHOPS	25 cu ft per min
ONS	30 cu ft per min
ATERS	from 20 to 30 cu ft per min
TING-HALLS	20 cu ft per min
OLS	30 cu ft per min per child and 40 cu ft per min per adult

The Usual Time-Intervals for One Air-Change are as Follows

HOTELS

Room	Air-change	Room	Air-change
gine-room	6 min	Café	8 min
chen	1½–5 min	Lobby under balcony	8 min
staurant	6 min	Main lobby	20 min
e-toilet	5 min	Banquet-hall	15 min
iard	10 min	Retiring-room	10 min
ber-shop	8 min	Kitchens	8 min
ing-room	15 min	All others	15 min
m-room	12 min	Toilets	6 min
fet	8 min		

LIBRARIES

ridors	15 min	Inside rooms	8 min
ement-rooms	15 min	Corner rooms	7 min
ding-rooms	12 min	Toilet-rooms	5 min

ndries should have an air-change every 4 to 6 min.

E. Radiation on sides of buildings subjected to prevailing and cold winds should eased 10% up to the 10th floor and 15% above that floor.

Ventilation-Laws. The number of VENTILATION-LAWS has increased ve rapidly in the last few years, not only as regards the number of states whi have added such laws to their codes, but also as to the scope and effectiveness these statutes. In many cases a special ventilation-officer or commission h been appointed to see to the enforcement and extension of the requirements f compulsory ventilation, so that it behooves the architect or engineer to becom thoroughly familiar with the law of the state or states wherein he practic A summary of the law recently enacted by the legislature of the state of Oh is given in the following paragraphs as an example of the regulations wi which architects and engineers must conform in preparing plans and specific tions. This law as well as the law of Massachusetts, attempts to provide ve definite regulations for heating and ventilating all classes of buildings. Futu legislation in other states will undoubtedly take a more specific form, establishi complete and definite codes for the heating and ventilation not only of publ buildings but of workshops, factories and mercantile establishments as well.

Requirements of the Department of Inspection of the Industrial Commission of Ohio for the Heating and Ventilation of Public Buildings, Hospitals, Asylums and Homes

Temperature

A heating system shall be installed which will uniformly heat the vario parts of the building to the following temperatures in zero weather.

THEATERS AND ASSEMBLY-HALLS. All parts of the buildings, except storag rooms, 65° F.

CHURCHES. Auditorium, social and assembly-rooms, 65° F. All oth parts of the building, except storage-rooms, 70° F.

SCHOOL-BUILDINGS. Corridors, hallways, play-rooms, toilets, assembl rooms, gymnasiums and manual-training rooms, 65° F. All other parts of t buildings, 70° F.

HOSPITALS, ASYLUMS AND HOMES. Operating-rooms, 85° F. All other par of the buildings, except storage-rooms, 70° F.

Change of Air

The heating system shall be combined with a system of ventilation which normal temperature will change the air the following number of times, or supp to each person the following number of cubic feet of air per hour.

THEATERS. Parlors, retiring, toilet and check-rooms, six changes per hour

AUDITORIUMS. 1 200 cu ft of air per person per hour.

ASSEMBLY-HALLS. When used in connection with a school-building, lod building, club-house, hospital or hotel, six changes per hour; and in all oth assembly-halls, 1 200 cu ft of air per hour per person.

CHURCHES. Auditoriums, assembly-rooms and social rooms, six changes p hour.

SCHOOL-BUILDINGS. All parts of the buildings, except corridors, halls a storage-rooms, six changes per hour.

ASYLUMS, HOSPITALS AND HOMES. (1) Rooms with fixed capacity:

	Adults	Children	Babies
ospitals, contagious and epidemic...........	6 000	4 000	3 000
ospitals, surgical and medical...............	3 000	2 400	1 500
ɛnal institutions..........................	1 800	1 800	...
ll other buildings..........................	1 800	1 500	...

) Rooms with variable capacities:

Hospitals, contagious and epidemic.................. 12 times per hour
Hospitals, surgical and medical..................... 12 times per hour
All other buildings................................ 6 times per hour

Rooms accommodating four or less persons need not be provided with a system ventilation.

Radiators

No radiator shall be placed in any aisle, foyer or passageway of a new theater, embly-hall or church, but such radiators may be placed in recesses in the lls.

Registers

Io floor-registers shall be used in theaters, assembly-halls, or hospitals.
Io floor-registers, except foot-warmers, shall be used in a school-building.
loor-registers may be used in churches.
therwise all vent-registers shall be placed not more than 2 in above the floor-, and warm-air registers not less than 8 ft above the floor-line (except when registers are used when a change of air is not prescribed).

Systems to be Installed Where a Change of Air is Required

he system to be installed when a change of air is required shall be either a ity or mechanical furnace system, gravity indirect steam system, or hot-water ɛm; mechanical indirect steam or hot-water system, or split steam or hot-r system; except in hospitals, where a direct-indirect system may be used nnection with an exhaust-fan. The fresh-air supply shall be taken from de the building and no vitiated air shall be reheated. All vitiated air shall nducted through flues or ducts and be discharged above the roof of the ling.

CEPTIONS. Standard ventilating stoves may be used in the following ings:

sembly-halls seating less than 100 persons.
urches seating less than 100 persons.
school-buildings, hospitals, asylums and homes.

Furnaces

naces may be used in all classes of buildings.

Gravity Indirect Hot-Water or Steam-Radiator Systems

irect hot-water or steam-radiators shall be located in basement fresh-air directly at the base of masonry hot-air flues, and shall be properly con-l to same with galvanized-iron housing.

Indirect Radiating-Surface for Heating and Ventilating Purposes

One square foot of radiating-surface shall be provided to heat not more than the following number of cubic feet of air per hour:

Height	Steam	Hot water
First story	200	125
Second story	250	160
Third story	300	200
Fourth story	250	235

For Heating Wall-Surfaces and Glass-Surfaces. The amount of radiating-surface for the heating of the glass-surface and wall-surface shall not be less than that obtained by adding together the glass-surface and one fourth the exposed wall-surface, both in square feet, and multiplying by the following factors:

Height	Steam	Hot water
First story	0.7	1.05
Second story	0.6	0.9
Third story	0.5	0.75
Fourth story	0.4	0.5

Accelerating or Aspirating Coils for Vent-Flues. Vent-flues used in connection with a gravity indirect steam or hot-water system shall be provided with accelerating coils placed 1 ft above the vent-openings.

Mechanical Fan Plenum System

This system shall be designed with furnaces, tempering coils or blast-coils so as to furnish heated air, and is to have cleaning-screens, fan plenum chambers, galvanized-iron or masonry horizontal ducts, masonry hot-air flues, electric motor, gas or gasoline engine, or a low-pressure steam-engine operating on a steam-pressure not to exceed 35-lb gauge to operate fan and such other device as is necessary to make this a complete working system. All parts and apparatus in connection with the installation are to be of ample size to make a perfectly free and easily working system, which must thoroughly heat all portions of the building without forcing.

Velocity of Air

The velocity of the air traveling through ducts, flues, etc., shall never exceed the following number of feet per minute:

Ducts, Flues, etc.	Feet per minute
Fresh-air screens, small mesh	600
Fresh-air ducts, gravity system	300
Fresh-air ducts, mechanical system	850
Tempering coils, gravity system	300
Tempering coils, mechanical system	1 000
Furnaces, gravity system	400
Furnaces, mechanical system	900
Trunk-ducts, mechanical system	1 000
Laterals, branches and single ducts, mechanical system	750
Vertical flues, mechanical system	500

'ertical warm-air flues, gravity system, first story	300
'ertical warm-air flues, gravity system, second story	350
'ertical warm-air flues, gravity system, third story	390
ertical vent-flues less than 20 ft high	300
ertical vent-flues from 20 to 33 ft high	350
ertical vent-flues from 33 to 46 ft high	390
ertical vent-flues from 46 to 60 feet high	440
'arm-air registers	300
ent-registers	300

Maximum Speed of Fans

The maximum speed of fans used in connection with either an exhaust or num system of heating or ventilating, under normal conditions, shall never eed the following:

ameter of fan in inches	18	24	36	48	60	72	96	120	180
volutions per minute	700	550	400	300	225	175	150	125	75

Location of Heater-Room

No heater-room shall be located under the auditorium, stage, lobby, passage-, stairway or exit of a theater; nor, under any exit, passageway, public hall obby of an assembly-hall, church, school-building, asylum, hospital or home. s applies to new buildings, and a changed location of a heater-room in an ting building. No cast-iron boiler carrying more than 10-lb pressure or l boiler carrying more than 30-lb pressure shall be located within the main s of any school-building.

Standard Fire-Proof Heater-Room for New Buildings

ll furnaces and boilers, including the breeching, fuel-rooms and firing-spaces be enclosed by brick walls not less than 12 in thick, or by monolithic con- walls not less than 8 in thick. The ceiling over the same shall not be less the following: reinforced-concrete slab, 4 in thick; brick arches, 4 in thick, red with 1 in of cement mortar and supported by fire-proof steel with the ssary tie-rods; or hollow-tile arches, 6 in thick, covered with 2 in of concrete, ered on the under side and supported by fire-proof steel with the necessary ods.

Specifications for Furnace-Work

e following form is given as a guide to architects in preparing the specifi- ns for furnace-work:

FICATIONS FOR FURNACE-WORK IN RESIDENCE FOR MR..........TO BE AT..........................

..................ARCHITECT

nace. Furnish and set up complete, where shown on basement-plan, one ame . . .) furnace, or approved equal, portable-pattern, with double casings. ct the furnace with the chimney with a No. 22 galvanized-iron smoke-pipe same size as the collar on the furnace; all bends or turns to be made with piece elbows; the pipe to be strongly supported by wire, and to be kept below the ceiling.

Pit. Excavate for and build a cold-air chamber under the furnace not an 18 in deep, with 8-in brick walls, laid and plastered with cement; also

cement the bottom of the chamber. Build the cold-air duct under cellar-floor where shown on plan, — ft long, 14 in deep in the clear, and — in wide, with sides of hard brick in cement, and with the sides and bottom smoothly plastered with cement. Cover the duct with 3-in flagstones with tight joints, leaving opening of proper side for the wooden box to be built by the carpenter (wooden box should be included in carpenter's specifications).

Hot-Air Pipes. Furnish and properly connect with furnace and register-boxes leaders and stacks of the following sizes, all to be made of bright IX tin, and the stacks are to be double with an air-space. All turns in leaders to be made by three-piece or four-piece elbows, and the stacks to have boots or starters of approved pattern.

Sizes of Pipes and Registers

Hall	11" leader,	no stack	12" × 14" register
Parlor	11½" leader,	no stack	12" × 15" register
Dining-room	12" leader,	no stack	12" × 15" register
Library	10½" leader,	no stack	12" × 14" register
Chamber No. 1	10" leader,	4" × 15" stack,	10" × 14" register
Chamber No. 2	9" leader,	4" × 13" stack,	10" × 12" register
Chamber No. 3	8½" leader,	4" × 13" stack,	10" × 12" register

Registers. All registers are to be of sizes given in the foregoing list, of the (...name...) or approved equal, manufacture; japanned, except those in the first story, which are to be electro-bronze-plated. All floor-registers are to be set in iron borders corresponding with the registers.

Register-Boxes. All register-boxes to be made double; for first-story boxes the JOISTS ARE TO BE LINED WITH TIN and provided with CEILING-PLATES the full size of the registers, with plaster-collars attached, so that pipes and boxes can be removed without disturbing the plastering or defacing the ceiling.

Miscellaneous. All horizontal pipes in the basement are to be round, and where they pass through partitions they are to be provided with collars, so that the pipes can be removed without disturbing the plastering. All leaders are to be provided with dampers and tin tags designating the different rooms they supply; and whenever pipes run near woodwork the same is to be properly covered with tin and protected from any danger from fire. The contractor is to remove all rubbish made by him, clean up all ironwork, leave the whole apparatus in complete working order, and furnish a poker of proper size.

Guarantee. The contractor is to guarantee, if he furnishes the heating drawings, that the furnace shall, under proper management, heat all rooms with registers connected with the furnace, to 70° F., when the temperature outside indicates 0°. In the event of the failure of the furnace to do this the contractor, at his own expense and without unnecessary delay, is either to make the furnace heat said rooms or substitute another furnace that will heat them.

Hot-Air-and-Water Combination-Furnaces

Combination-Furnaces. It is quite difficult, if not impossible, to heat dwellings covering throughout, more than 1 400 sq ft with warm air alone. On account of the much larger exposure and the increased length of leaders it becomes necessary to supplement the warm air with an auxiliary heat whi

be carried to remote and exposed parts of the house, and which will not ffected by pressure of wind or long and crooked pipes. For supplying this iary heat, hot water has been found best adapted as a rule, and a variety OMBINATION-FURNACES are now made which contain provisions for heating r which may be carried by pipes to radiators located in those parts of the e most difficult to heat by warm air. Such combination-systems have used with success. The construction of the parts for heating the water s with different makes of furnaces. Some furnaces have a portion of the ot hollow, and the water is heated there; others have a separate heater nded over the fire-pot. As a rule, the parts of the house which should eated by the hot water are the halls, bath-rooms, and perhaps the s on the north or west sides of the house. The same rules govern the of the radiators and piping and the manner of installing as in an entire ater plant.

Specification for Hot-Water Heating-Apparatus in a Residence

s specification contemplates a complete upfeed two-pipe gravity hot-water g system, to be installed in accordance with the drawings covering the

ter. Furnish and set up in cellar, where shown on plan, one (. . . name . . .) boiler, or approved equal, guaranteed free from all flaws and defects. eater to be set on a substantial foundation of hard brick laid in cement r and put in by the heating-contractor. Furnish and deliver one set of ols, consisting of one poker, one slice-bar and one fine brush and handle.

ke-Pipe. Connect the boiler to the chimney by means of smoke-pipe of No. 22 galvanized iron, the diameter of the pipe to be equal to the on the heater.

mings. The boiler is to be provided with one thermometer registering o° F. to 250° F., and one Standard altitude gauge.*

er-Connections and Blow-off. Feed-water with its supply-pipe will be t within 6 ft of the boiler by the plumber and left with one ¾-in cast-iron for boiler-connection, which is to be made by this contractor, with suit-ck. Draw-off cock to be placed on lowest point of system and to be or hose-attachment.

. Furnish and run all necessary flow and return-mains of ample size, ing them to radiators with risers of ample size to insure the free flow vater to and from the radiators. All connections from risers to radiators ade below floors.

ity of Materials. All materials used in the construction of this apparatus e the best of their respective kinds, all fittings to be heavily beaded and f the best gray iron with clean-cut threads, and, when practicable, Y's L's are to be used.

ing. The ends of all pipes used in the construction of this apparatus e reamed and all obstructions removed before pipes are placed in position. and return-mains in the basement are to be supported by neat, strong, le hangers, arranged to suit expansion and contraction, and properly to timbers overhead. At all points where pipes pass through ceilings,

* ltitude-gauge indicates the amount of water in the system and is a convenient at which avoids the necessity of consulting the gauge-glass in the tank. It pensed with if desired.

floors, or partitions, tin thimbles are to be provided and the holes protect with floor or ceiling-plates.

Expansion-Tank. The expansion-tank is to be constructed of galvanized ir and is to be furnished with a proper gauge-glass with brass mountings comple It is to be placed at least 3 ft above the highest radiator in a suitable pl and supported on a proper shelf. From this tank an overflow-pipe will run to the basement or other suitable place with a vent-pipe through the r properly flashed.

Radiators. Furnish, set up, and pipe the following radiators:

Rooms	Number of radiators	Radiating-surface, sq ft
Main hall	1 indirect radiator	108
Sitting-roon	1 indirect radiator	120
Library	1 direct radiator	40
Dining-room	1 direct radiator	60
Sitting-room chamber	1 direct radiator	40
Library chamber	1 direct radiator	44
Dining-room chamber	1 direct radiator	36
Kitchen chamber	1 direct radiator	32
Bath-room	1 direct radiator	32
	9 radiators	512

In all there are to be 284 sq ft of direct surface and 228 sq ft of indirect; to surface, 512 sq ft. The direct radiators to be (...name...) hot-water patte or approved equal, 38 in high.

Air-Valves. Each radiator is to be provided with a nickel-plated key-ty air-valve.

Radiator-Valves. Each direct radiator is to be promptly connected to t system of piping with a quick-opening nickel-plated radiator-valve and un elbow.

Indirect Radiation. The indirect radiators are to consist of two stacks (...name...) hot-water radiation, or approved equal, connected toget with tight joints and firmly suspended from the basement-ceiling by suita wrought-iron hangers. The stacks are to be so piped and hung as to per a noiseless and constant flow throughout of the heated water. Each st is to be enclosed in a galvanized-iron chamber with proper fresh-air inlet-d and a corresponding outlet-duct for warm air, connected to the register in t room which the stack is intended to heat. The registers are to be of t (...name...) pattern, electro-bronze-plated, and of the following sizes: h 12 by 19; sitting-room, 14 by 22 in. Registers are to have floor-borders a to be set in register-boxes. The duct connecting the stack and register be so arranged that all fresh air coming in will be properly heated and c veyed, with least loss, to its destination. In arranging indirect boxes, c is to be exercised in getting ample space for cold air under the stack, an corresponding space for warm air over the stack.

Covering of Pipe. All flow and return-pipes and fittings in cellar above floor are to be properly covered with 1-in hair-felt neatly sewed up in can

nd painted one coat of good white lead, or covered with asbestos or magnesia ctional covering, with canvas cover, and secured by lacquered-brass bands.

Boiler-Covering. All exposed parts of the boiler, except the front, are to e covered with plastic asbestos, 1½ in thick, neatly applied and troweled, nooth.

Workmanship. All work is to be done in a neat, substantial and workman- e manner, and the apparatus, when completed, is to be thoroughly tested d left in good working order.

Guarantee. The contractor is to guarantee, if he is to furnish the heating- wings, that the apparatus he installs will be of ample capacity to evenly intain a temperature of 70° F. in the rooms in which radiators are located. en the outside temperature is at zero, and that the apparatus throughout l have a free circulation when in operation.

Steam-Heating for Residences

General Requirements. For very large residences, the author would ommend steam-heat, all of the principal rooms to be heated by indirect iation, and only the bath-room, halls, and perhaps the attic and one or two ns on the north side, which generally includes the dining-room, by direct ation. For dining-rooms a special direct radiator, containing a warming- et, is made. The air-supply to the indirect stacks should be very large provided with a damper, so that the supply may be regulated according he weather. The boilers used in residence-heating are generally of the cast- sectional type described on page 1278. The single-pipe system is com- ly used in dwellings, all indirect radiators, however, being two-pipe.

Specification for a Low-Pressure Steam-Heating Apparatus for Heating by Direct Radiation

tention. This specification is intended to cover everything necessary to finish and install in the above-mentioned building a complete steam-heat- ystem in strict accordance with the plans and this specification, as prepared ———, architect.

ns. The drawings herewith are intended to show only the location of the r, piping and radiators; the arrangement of the piping will be left largely e contractor, subject to the approval of the architect.

neral Requirements. This contractor is to provide all necessary tools and nces for the erection and completion of the work, and when completed, remove all apparatus, refuse and débris from the building and grounds, g the work in a clean, uninjured and perfect condition. No cutting of escription tending to weaken the building structurally is to be undertaken ut consulting the architect. This contractor is to be fully responsible for fety and good condition of the work and material embraced in this contract he completion and acceptance of the same. All work is to be of the best y, and should at any time improper, imperfect, or unsound material or workmanship be observed, whether before or after same has been built e structure, this contractor, upon notice from the architect, is to remove nd substitute good and proper material and workmanship without delay e thereof, in default of which the architect is to effect same by other as may be deemed best, and is to deduct the cost of such alterations from n due the contractor under this contract.

System. The heating is to be effected by direct radiation distributed throu out as shown on the drawings, and the circulation of the steam is to be by one-pipe circuit system.

Boiler. This contractor is to build the foundation for the boiler, whi shown, 12 in deep, of common hard brick laid in cement mortar. He is leave an ash-pit for the boiler of proper size, 12 in deep, cemented, and ma water-tight. He is to furnish and set up one (...name...) cast-iron section or approved equal, boiler, provided with 6-in low-pressure brass-cased stea gauge, water-gauge, and glass, gauge-cocks, combination-column, safety-valv and blow-off valves, and all other usual and necessary trimmings to compl the boiler,* and a full set of fire-tools, consisting of one slicing-bar, one h one poker, and a cleaning-brush. He is to cover the boiler with 1 ½-in of asbes cement, neatly troweled to a smooth finish.

Water-Supply. The plumber is to bring the water-supply to within 6 ft boiler, but this contractor is to make connection with boiler with ¾-in ir pipe, stop-cock and check-valve.

Smoke-Pipe. Contractor is to connect the boiler with the chimney with round smoke-pipe made of No. 22 galvanized iron with suitable balance-dampe This connection to be of same size as left for this purpose by maker of boiler.

Main Pipes and Risers. The steam-main is to be run full size for the enti length and provided with an automatic air-vent at the end of the run. It to be of ample size to carry all the risers and radiators attached to the syste and is to be graded 1 in in 10 ft in the direction of the flow. From the top this main the various branches are to be taken to radiators and risers, t connections for which are to be so made that no traps are formed. If a tr cannot be avoided, a drip connected with the return-main is to be installe Radiators on first story are to be connected direct to steam-main. Radiato for the second and third floors may be taken off the same riser. The mai after serving the last radiator, is to drop below the water-line of the boil and its size reduced, and it is to run back to the boiler as a wet-return-mai The steam-main at the end of the run is to be 24 in or more above the water-li of the boiler. The boiler is to be installed in a pit if necessary to accompli this.

Pipes and Fittings. All pipe used throughout is to be of the best quali wrought-iron or steel pipe of standard weight and thickness, with the en reamed, free from imperfections, and true to shape. All threads are to clean-cut, straight and true. All fittings are to be of the best heavy gray ir with taper-threads, and are to be heavily beaded. No inferior pipe or fitti will be allowed.

Supports. All piping is to be supported by approved expansion-hangers rollers, not to exceed 10 ft apart. Neat cast-iron floor and ceiling-plates to be used where pipes pass through floors, ceilings and partitions.

Radiators. Direct radiation is to be furnished to the amount enumerated the drawings of the (...name...) make, or approved equal.

Radiator-Valves. The radiators are to be furnished with removable di type union valves, rough nickel-plated, and are to have hard-wood hand-whee

Air-Valves. Radiators throughout the entire building are to be furnis with (...name...) automatic air-valves, or approved equal.

* For house-heating plants it is well to specify also "one automatic damper-regul of approved pattern, with connection for operating draft-door and cold-air check."

Pipe-Covering. All pipes in the cellar above the floor are to be covered th 1-in asbestos (or magnesia) sectional covering with canvas cover and ured by lacquered-brass bands.

Painting and Bronzing. All radiators and exposed pipes in rooms or halls to be neatly painted two coats of best radiator-enamel, or bronzed in desired ors.

Finally. When completed, the apparatus is to be tested to 10-lb steam-ssure and made tight at that pressure, said test to be conducted under the ervision of the architect. Fuel for the test is to be furnished by the owner, when accepted, the apparatus is to be turned over to the owner in com-e working order. All valves and stuffing-boxes are to be properly packed the plant completed in all its parts, it being understood that this contractor furnish all miscellaneous material, tools, labor, etc., necessary to complete work in a first-class and workmanlike manner.

uarantee. This contractor is to guarantee that when the apparatus is pleted it will be free from all mechanical defects and, if he is to furnish design and layout, that the installation shall be of ample capacity to heat ooms where radiation is placed to a temperature of 70° F. when the outside perature is 0° F.

CHIMNEYS*

By

L. A. HARDING

FORMERLY PROFESSOR OF MECHANICAL ENGINEERING, PENNSYLVANIA STA[TE]
COLLEGE

Draft. To burn a fuel at a given rate (pounds per square foot of grate-surfa[ce] per hour) requires a definite weight of air to be supplied for combustion. Th[e] air passes under the grate and through the fuel-bed and meets with considerab[le] resistance in its flow, not only through the fuel-bed, but through or around th[e] boiler-tubes and smoke-flue or breeching. The motive force causing the air-flo[w] in a natural-draft plant is supplied by the chimney. The difference betwe[en] the atmospheric pressure and the pressure existing at any point in the furna[ce] or in the flue is termed the DRAFT at that particular point. This pressure [is] ordinarily measured by means of a U tube filled with water, the draft bein[g] recorded in inches of water, and is the difference in the heights of the wate[r] columns in the two legs of the U tube.

Height. The INTENSITY OF DRAFT that a chimney is capable of producing [at] the base is a function of its height, the temperature of the flue-gases, and th[e] temperature of the outside air, which is generally assumed to be 60°. The tem[-]perature of the flue-gas is ordinarily assumed to be 550°. The intensity [of] draft produced, per foot height, measured in inches of water is

$$H = 0.0071\, L$$

L = height of chimney above grate, in feet. The flue-gas temperature is tak[en] at 550° and the outside temperature at 60°. Ordinarily $0.8H$ is taken as rep[-]resenting the AVAILABLE DRAFT, in order to allow for the cooling of the chimne[y] gases. Then $0.8H$ must be equal to or greater than the sum of the expecte[d] draft-losses as given in the following paragraphs.

Draft-Losses. The DRAFT-LOSSES through the fuel-bed depends upon th[e] rate of combustion required and the kind of fuel. This loss may be approx[i-]mated by using the data in Table I.

The LOSS OF DRAFT between the grate or furnace and a point just beyond th[e] damper-box of a boiler is about as shown in Table II when the boilers are oper[-]ated at normal rating; bituminous coal burned at the rate of from 25 to [3x] lb per sq ft of grate-surface per hour.

The loss of draft through the boiler will depend largely upon the method [of] baffling employed, and increases with the per-cent rating at which the boiler [is] operated. The precipitating-figures should be increased by approximate[ly] 55% when the boiler is operated at 150% of its rated capacity, and by 75[%] when it is run at 200% rating.

Velocity of Gases through Flue and Chimney. In preliminary estimat[es] 5 lb coal per boiler horse-power developed, and 24 lb air per lb of coal is usual[ly]

* See, also, Chimneys for Heating Boilers, page 1281; Flues for Kitchen Ranges [and] Fireplaces, page 1282, and Selection of Chimney Flues, page 1282.

ed. The customary allowable VELOCITIES OF GASES in chimneys, when sign is based on 120 lb of the flue-gas per hour per rated boiler horse-power, from 17 ft per sec for a diameter of stack equal to 24 in, to 31 ft per sec 72-in or larger diameter. These figures correspond to a weight of 0.68 10 lb per sq ft of area. The formula that is supposed to give the most nical diameter for an unlined steel chimney or stack, and used by many ers in this country is $d = 4.68\sqrt[5]{(\text{h.p.})^2}$, in which d is the inside diameter es and *h.p.* is the rated capacity of the boilers served.

following figures are frequently used by engineers for approximating the draft in flues or breechings:

Horizontal flues, square or rectangular, from 0.13 to 0.15 in of water per Increase these values 50% for brick-lined flues. Loss of draft for easy ngle bends, 0.05 in of water.

When economizers are to be installed the temperature of the flue-gas is l to from 250° to 325°, and the total head, H, should be calculated on a these temperatures.

The loss of draft through the economizers should not be figured less 3 in of water.

The turns which the flue makes in leaving the damper-box of the boiler, enters the main flue and at the stack, should be considered and allowed

t is customary to make the flue or breeching approximately from 10 to eater in area than the stack to which it connects. The cross-section is re-n proportion to the volume of gas to be handled as the flue passes the n succession. The width of the flue or breeching, where it enters the

chimney, should never exceed one third the outside diameter of the chimney its base.

Example. The method of procedure in determining the dimensions o chimney and breeching is explained in the following example.

Three 150-1 h.p. return tubular boilers with a total of 1 500 sq ft of heati surface are to be served. The total area of the grate-surface is 90 sq ft. measured length of the breeching is 40 ft. The gas makes two right-angle tu one at the entrance to the breeching, and one on entering the chimney. fuel assumed is Pennsylvania bituminous coal. If 5 lb of coal per boiler ho power per hour is assumed as the fuel-consumption, the rate of combustio $(3 \times 150 \times 5)/90 = 25$ lb per sq ft of grate-surface per hour.

The weight of flue-gas per second is

$$(3 \times 120 \times 150)/(60 \times 60) = 15 \text{ lb}$$

Assuming a temperature of 550°, the volume of the flue-gas per secon $15/0.0393 = 382$ cu ft. Assuming an allowable velocity through the chimn area of 25 ft per sec, the required area is,

$$382/25 = 15.3 \text{ sq ft}$$

corresponding to 54-in diam, approximately The area of the flue is to 15% greater, or

$$15.3 \times 1.15 = 17.6 \text{ sq ft}$$

at the last boiler next to the chimney. The chimney must produce suffici draft to overcome the following resistance. The loss of draft through fuel- based on a rate of combustion of 25 lb per sq ft per hr (Table I) is 0.31 in. loss of draft through return tubular boilers (Table II) is 0.27 in. The los draft through the breeching is

$$0.15 \times 40/100 = 0.06 \text{ in}$$

The loss of draft occasioned by two turns is

$$2 \times 0.05 = 0.10 \text{ in}$$

The total loss is

$$0.31 + 0.27 + 0.06 + 0.10 = 0.74 \text{ in}$$

Then

$$H = 0.74/0.8 = 0.92 \text{ in}$$

or approximately 1 in.

Substituting this value of H in the equation

$$H = 0.0071L$$

the height, L, of the stack is

$$1/.0071 = 140 \text{ ft}$$

measured above the grate.

Kent's Chimney-Formulas. The following chimney-formulas by Wi Kent are largely used by engineers in this country: The formula is base the assumption that the friction-head in the chimney is considered equiv to a diminution of the area by an amount equal to a lining of inert gas, 2 thickness.

Table III. Size of Chimneys for Steam-Boilers

If A = the actual area in square feet;
E = the effective area in square feet;
D = the diameter in feet;

Then $E = A - 0.60\sqrt{A}$.

The draft-power of a chimney varies directly as the effective area, E, and as the square root of the height, L. The formula for the horse-power of a chimney will take the form, $h.p. = CE\sqrt{L}$, in which C is a constant. The value of C as obtained by Kent from an examination of a large number of chimneys is 3.33 when 5 lb of coal is burned per boiler horse-power per hour.

The formula for the horse-power rating of a chimney is, therefore,

$$\text{h.p.} = 3.33E\sqrt{L} = 3.33\,(A - 0.6\sqrt{A})\sqrt{L}$$

or

$$E = 0.3\ \text{h.p.}/\sqrt{L}$$

The Babcock & Wilcox Company recommend that when the fuel used is low grade bituminous coal of the Middle or Western States, the sizes given in Table III be increased from 25 to 60%, depending upon the nature of the coal and the capacity desired. If the gas makes more than two turns it is advisable to increase the diameter given in the table by one size. The height must be increased at least 30% if economizers are used. Table III may be applied to heating-boilers, the equivalent rating in square feet of direct radiation being approximately equal to the horse-power rating × 100.

Chimneys for Tall Office and Loft-Buildings. The chimney or stack for a tall building is a special case in which the height is frequently fixed by the height of the structure itself or the height of the adjoining buildings. In this case a diameter is assumed and the method outlined in the preceding example applied.

General Formulas for the Design of Brick Chimneys. See Fig. 1

Let P = horizontal wind-pressure in pounds per square foot, ordinarily assumed as 25 lb per sq ft for round chimneys

xx = any section distant z from top of chimney

$z\left(\dfrac{d + d_1}{2}\right)$ = projected area above xx

R = horizontal wind-load in pounds

$= Pz\left(\dfrac{d + d_1}{2}\right)$

y = distance from xx to center of gravity of portion above xx

M = wind-moment in foot-pounds

$= Pzy\left(\dfrac{d + d_1}{2}\right)$

Properties of Section

d_1 = outside diameter

d_2 = inside diameter

$c = d_1/2$

I = moment of inertia of section

A = area of section in square feet

$= 0.7854\,(d_1^2 - d_2^2)$

$\dfrac{I}{c}$ = section-modulus

$\frac{I}{c} = \frac{0.0982\,(d_1^4 - d_2^4)}{d_1}$

W = weight of chimney above xx, in tons

S_1 = compressive stress at edge on leeward side due to W, in tons per square foot

S_2 = compressive stress at edge on leeward side due to M, in tons per square foot

$S_1 = +\frac{W}{A} \qquad S_2 = \pm \frac{Mc}{I}$

$$\text{Windward side, } S_w = \frac{W}{A} - \left[\frac{Mc}{I}\text{ (tension)}\right]$$

$$\text{Leeward side, } S_l = \frac{W}{A} + \left[\frac{Mc}{I}\text{ (compression)}\right]$$

S_w and S_l should not exceed the following values, in tons per square foot, for dial Brick Chimneys:

Maximum tension		Maximum compression	
Below 150 ft........	2 to 2½	200 ft and below.........	19
From 150 to 200 ft...	1 to 1½	Above 200 ft.............	21
Above 200 ft........	0		

'oundations. Calculate wind-moment, M_1 for chimney above ground-line.

$M_1 = Ph\,y_1 \left(\frac{d + d_2}{2}\right)$

l = length of side of square base in feet

$l_1 = l^2$ = area of base in square feet

$\frac{I}{c} = \frac{l^3}{6}$ = section-modulus of base

W_1 = combined weight of chimney and foundation

ample. It is required to determine the maximum compression, in tons per t at the base of the column, for the chimney shown in Fig. 2, and also the imum soil-pressure in tons per sq ft. The assumed wind-pressure is 25 lb q ft. (See General Formulas for the Design of Brick Chimneys, and Fig. 1.)
he area of section at base, $A = 0.7854\,(16^2 - 12.3^2) = 80.9$ sq ft.
he section-modulus at base, $I/c = [0.0982(16^4 - 12.3^4)]/16 = 257$.
he total weight of brick column (Table V) is $W = 495$ tons (interp olated).
he projected area of column is $\frac{1}{2} \times (8.75 + 16) \times 180 = 2\,228$ sqft.
he horizontal wind-load, $R = 2\,228 \times 25 = 55\,700$ lb = 27.8 tons.
he moment-arm of R is $y = \frac{1}{3} \times 180[(2 \times 8.75) + 16]/(8.75 + 16) = 81$ ft.
he wind-moment, $M = 81 \times 27.8 = 2\,252$ ft tons.
$= 495/80.9 = 6.2$ tons per sq ft.
$= \pm 2\,252/257 = 8.7$ tons per sq ft.
e maximum compression on the leeward side, $S_1 + S_2 = 6.2 + 8.7 = 14.9$ per sq ft. The maximum tension on the windward side, $S_1 - S_2 = -2.2$ per sq ft. The following computations are for a square base:
undation. The length of base, $l = 25.5$ ft, $A_1 = l^2 = 650$ sq ft, $I/c =$ /6 = 814. The weight of foundation, based on 1.9 tons per cu yd, is 266 The weight of the 4½-in lining is $36 \times 11 \times 0.063 = 25$ tons. The total t of column, lining and foundation, is $W_1 = 495 + 25 + 266 = 786$ tons. e moment-arm for R may be assumed the same as before, or 81 ft. Ther 2 252 ft-tons. The section-modulus of the base, $I/c = l^3/6 = 814$.
$= 786/650 = 1.2$ tons per sq ft. $S_2 = 2\,252/814 = 2.8$ tons per sq ft.
e maximum soil-pressure, $S_1 + S_2 = 1.2 + 2.8 = 4$ tons per sq ft.

$+S_1$

$+S_2=$

$+S_3=$

Tons per square foot

$$S_1 = \frac{W_1}{l^2} = \text{compression per sq ft due to } W_1$$

$$S_2 = \frac{6M_1}{l^3} = \text{compression per sq ft due to } M_1$$

ese values are interpolated from curves by the M. W. Kellogg Company. The n unit soil-pressure at the outer edge of the foundation, due to dead and wind-es not exceed 2 tons per square foot.

forced-Concrete Chimneys. Area of Steel Reinforcement Re- The following formulas are used by one concern in the design of rein-oncrete chimneys:

= wind-moment at section considered, in inch-pounds;

= weight of shell above section considered, in pounds;

D = outside diameter of shell, in feet;
d = inside diameter of shell, in feet;
R = radius of steel circle, in inches;
r = radius of neutral core = $\frac{1}{8}D[1 + (d/D)^2]$ feet;
WR = moment of stability from weight of shell, in inch-pounds;
S = 16 000, the allowable fiber-stress in the steel in pounds per square in
A = total cross-sectional area of steel rods required at section considered, square inches;
$A = 2(M - Wr)/SR$ = number of bars × cross-sectional area of one ba

The bars used are ordinarily ¾-in square, twisted bars, each with a cro sectional area of 0.5625 sq in. The thickness of the shell, if made without taper, is ordinarily 6 in, and if constructed with a taper the shell is made 5 in thickness at the top and increased ¼ in in thickness for each 5 ft in heig The maximum compression due to the wind-moment and dead load in t concrete, at the base, is ordinarily limited to 350 lb per sq in. The same formu apply in this case as in the design of brick chimneys (Fig. 1).

Example. A reinforced-concrete chimney has the following dimensio 150 ft high; no taper; 9 ft inside diameter; thickness of shell 6 in; outsi diameter 10 ft; weight of shell 335 250 lb. It is required to determine the to cross-sectional area of reinforcement.

$M = 25 \times 10 \times 150 \times 150/2 = 2\,812\,500$ ft-lb $= 33\,750\,000$ in-lb;
$r = 10/8 \times [1 + (9/10)^2] = 2.3$ ft $= 27.6$ in;
$R = 58$ in;
$A = 2[33\,750\,000 - (335\,250 \times 27.6)]/16\,000 \times 58) = 53$ sq in;

If ¾-in square bars are used, it requires $53/0.5625 = 94$ bars.

ig. 3. Details of Tall Reinforced-concrete Chimney

himney Company, Chicago, Ill., designed and constructed, chimneys, the great reinforced-concrete chimney at Saganoseki, riental Compressol Company, for the copper smelter. It was uary, 1917, and ranks with the highest in the world, being foundations and 26¼ ft in internal diameter at the top.

Self-Sustaining Steel Chimneys* are largely used, especially for tall chimneys of iron-works and power-houses from 150 to 300 ft in height.

"The advantages claimed are: Greater strength and safety; smaller space required; smaller cost by 30 to 50% as compared with brick chimneys; avoidance of infiltration of air and consequent checking of the draught, common in brick chimneys. They are usually made cylindrical in shape, with a wide curved flare for 10 to 25 ft at the bottom. A heavy cast-iron base-plate is provided, to which the chimney is riveted, and the plate is secured to a massive foundation by holding-down bolts. No guys are used."†

The largest SELF-SUSTAINING STEEL CHIMNEY in the world (1919) is that built by the Chicago Bridge and Iron Works at the plant of the United Verde Copper Company, Clarkdale, Arizona. It is 30 ft 9½ in in diameter and 400 ft in height. The thickness of plates varies from ¼ in at the top to 11/16 in for the bell-shaped portion at the bottom. The weight of steel is 800 000 lb. The stack is anchored to the foundation by thirty-six bolts, each 4 in in diameter, upset, and spaced equidistant in a bolt-circle of 25 ft 4½ in radius.

Table VIII. Sizes of Foundations for Self-Sustaining Steel Chimneys, Half-Lined‡

The governing feature in the design of a SELF-SUSTAINING STEEL CHIMNEY OR STACK is the force of the wind. The cylinder above any horizontal plane section may be assumed to act as a cantilever beam in which the bending moment, in foot-pounds, is

$$M = HD \times P \times \tfrac{1}{2}H = \tfrac{1}{2}H^2DP$$

in which H is the height in feet above the section considered, D the diameter in feet and P the assumed pressure of the wind in pounds per square foot on a vertical cross-section. The fiber-stress S, in pounds per square inch, according to the formula for flexure, is $S = Mc/I$. For hollow cylinders of large diameter and small thickness, the moment of inertia $I = \pi R^3 t$, in which R = mean radius in feet (equivalent to c in the flexure formula) and t = thickness of shell in inches. Hence

$$S = MR/12\pi R^3 t = 0.106M/D^2 t, \quad \text{and} \quad t = 0.106M/SD^2.$$

The stress S is tensile on the windward side and compressive on the leeward side.

‡ These dimensions were taken from a pamphlet published by the Philadelphia Engineering Works.

small compressive stress due to the weight of the stack. The
be taken at 25 lb per sq ft and of S at 16 000 lb per sq in, as given
tions for the Structural Steel Work for Buildings, Chapter XXX.
ouilt for durability as well as strength it is often advisable to
oretical thickness of the shell. No plate should be used with a
han ¼ in. It is important that the stack be securely anchored
n. Many methods have been proposed for determining stresses
As the problem depends for its solution on the physical con-
base and bolts, no exact analysis is possible. (See editorial dis-
icle, Anchor-Bolt Tension, in Engineering News, April 30, 1914.)
assumption is that the bolts are screwed up with a high initial
nchor-bolt ring can then be considered in the same way as a ring
The maximum stress at any point of the bolt-circle is devel-
wind is blowing parallel to the radius through that point. The
ircumferential inch is $0.106M/(2R_1)^2$, $2R_1$ being the diameter
le. Let b be the circumferential distance in inches between
-bolts, N the number of bolts equidistant on the bolt-circle and
the stack. For the anchor-bolt on the windward side there is a
, due to the wind,

$$S_w = 0.106bM/(2R_1)^2$$

$$b = (2R_1 \times 12 \times \pi)/N$$

$$S_w = 2M/R_1N$$

eight of the portion of the stack between adjacent bolts, the
stress in any anchor-bolt may be expressed by the equation

$$S_w = (2M/R_1N) - W/N$$

Chimneys. These chimneys are built with special blocks
ne circular and radial lines of each section of the chimney so
brickwork has joints of an even thickness throughout and a
surface. The blocks being much larger than common bricks,
om one third to one half as many joints. Radial-brick chim-
ircular in plan above the base. The best form of base is octag-
ion so as to permit the breeching to enter the chimney at a
at the same time comply best with the rules of stability.
cal-works, refineries, furnaces, etc., radial-brick chimneys are
e shell, a lining only being provided in the immediate vicinity
ce. All radial bricks are perforated vertically and this insures
and allows the mortar to enter the perforations, thus forming
ige.
for chimney-construction have been used extensively in
y, France and Russia since 1870. They were not introduced
however, until 1898. About forty-five years ago (1869 or
stodis, of Düsseldorf, Germany, originated a method of building
erforated radial blocks, made from selected clays and burned
mperature, and in 1898 an American company * was formed
f erecting chimneys by this method of construction. Since

stodis Chimney Construction Company, New York City.

that time the company through various agencies has built more than six thousand chimneys in all parts of the world. The tallest chimney in the world (1919), 585 feet high and 60 ft in internal diameter at the top, was built by this company in 1918 for the Anaconda Copper Company, at Anaconda, Mont.

Mr. H. R. Heinicke,* of Chemnitz, Germany, builder of the 460-ft stack at Halsbrücke, Germany, has employed radial bricks made especially for each chimney. This firm through long and costly research has done much to make chimney-building a science. The chimney at Halsbrücke is a very remarkable one on account of its proportions. In a height of 460 ft, the diameter at the top is only 8 ft, whereas the 585-ft stack at Anaconda, Mont., has a diameter of 60 ft at the top.

The Heine Chimney Company † has erected many important high chimneys. The essential difference in the methods of construction used by this company from those of the other chimney-constructors is that the Heine Chimney Company uses perforated, INTERLOCKING, radial bricks. It is claimed that this interlocking-feature has an advantage over the straight-sided bricks in acting as a preventive of deep weathering of the joints and of air-leaks. In addition to this it is claimed that the circumferential strength of the walls when built of this type of brick is considerably greater than when built with plain-sided or corrugated bricks. The perforations in these bricks are fewer but larger than those of some of the other constructors. The brickwork is laid on full-mortar beds with SHOVED joints. These large perforations allow the mortar to rise in them, thus forming PINS which give the walls great strength and enable them to withstand the stresses due to expansion caused by the high temperature of the flue-gases. In walls more than one brick thick, the bricks are laid up in English bond, that is, with alternate header and stretcher-courses. This company advocates this method of construction even in chimneys built with the ordinary straight-sided common building-bricks. Among the many important chimneys constructed by the Heine Chimney Company is the one erected at the St. Joseph Lead Company's plant, at Herculaneum, Mo. The height of this chimney is 350 ft and the inside diameter at the top 20 ft. (See page 1706.)

The M. W. Kellogg Company ‡ has designed and built many radial-brick chimneys for power-plants, chemical-works and other purposes. Several of the important chimneys put up by them are mentioned in the list of tall chimneys (page 1379). Some of the details of construction differ from those of the other companies mentioned. One of the points of difference is the detail relating to the corrugations on their bricks. These corrugations are 3/8 in wide and 1/4 in deep and are placed along the vertical sides of the bricks as they lie in the wall. The adhesion between the bricks and mortar is increased by this increased area. It is claimed that tests made show that this is the case. On account of these corrugations it is not considered necessary to embed any ironwork in these chimneys to prevent the development of cracks due to heat-expansion. Ironwork has sometimes been inserted when plain-sided bricks have been used. It is claimed that this design is somewhat heavier than that employed by some other constructors, this company holding that it is not safe to figure on wind pressure of less than 25 lb per sq ft of projected area. Among the many tall chimneys erected by this company may be mentioned especially the

LICS, PLUMBING AND DRAINAGE, ILLUMINATING-GAS AND GAS-PIPING

BY
J. J. COSGROVE
CONSULTING SANITARY ENGINEER

(1) HYDRAULICS

ctically an incompressible liquid, weighing, at the average temper-
62.355 lb to the cu ft and 8.335 lb to the gallon. These figures
with changes in temperature and atmospheric pressure, and a
for the same temperature will be found in different works.

Water. The pressure of still water in pounds per square inch
s of any pipe or vessel of any shape whatever is due alone to the
of the surface of the water above the point considered pressed
qual to 0.433 lb per sq in for every foot of head at 62° F. The
er square inch is equal in all directions. To find the total pres-
ater against and perpendicular to any surface, whether vertical,
inclined at any angle, whether it be flat or curved, multiply
ea in square feet of the surface pressed, the vertical depth of its
ty below the surface of the water, and the constant 62.4. The
the required pressure in pounds. This may be expressed by
ws:

$$P = 62.4\, AD$$

essure in pounds of quiescent water on the surface considered;
ea pressed upon in square feet; and
rtical depth in feet of center of gravity of surface considered.

Pressure in Pounds per Square Inch for Different Heads of Water in Feet

1	2	3	4	5	6	7	8	9

for greater heads can be readily found by multiplication or addi-
pressure for a head of 110 ft is ten times that for 11 ft. The pres-
s equal to the pressure for 110 ft plus that for 8 ft.

Flow of Water in Pipes. Owing to the many practical and variable conditions which affect the flow of water in pipes, such as the smoothness of the pipe, number and character of the joints, bends and valves in the pipe, to say nothing of the size and length of the pipe, all formulas for the velocity and discharge of water in and through pipes can only be considered as approximate. The following formulas and data are taken largely from the National Tube Company's Book of Standards, 1902 edition. They agree fairly well with similar tables by Kent and Trautwine, both of whom devote much space to this subject. The QUANTITY OF WATER passing through a given pipe is governed by the sectional area of the pipe or outlet and the mean VELOCITY. The velocity depends primarily upon the PRESSURE or HEAD, and is greatly affected by FRICTION, which again varies with the smoothness of the bore, the diameter and length of the pipe, and whatever obstructions there may be in the pipe. The HEAD is the vertical distance from the surface of the water in the reservoir to the center of gravity of the lower end of the pipe when the discharge is into the air, or to the level surface of the lower reservoir when the discharge is under water. When the pressure is produced by mechanical means, the head of water in feet may be readily determined by the following table:

Table B.* For Converting Pressure in Pounds per Square Inch into Head of Water in Feet

Pressure	0	1	2	3	4	5	6	7	8	9

* Tables A and B are exact for water at 62° F. and for atmospheric pressure at 14.7 lb per sq in.

To find the velocity of water discharged from a pipe-line longer than four times its diameter, knowing the head, length and inside diameter, use the following formula:

$$v = m\sqrt{\frac{hd}{L + 54d}}$$

in which

- v = approximate mean velocity in feet per second;
- m = coefficient from the table below;
- d = diameter of pipe in feet;
- h = total head in feet;
- L = total length of line in feet.

The following coefficients are averages deduced from a large number of experiments. In most cases of pipes carefully laid and in fair condition, they should give results varying not more than from 5 to 10%.

Values of Coefficient m

Diameter of pipe in feet							
0.05	0.10	0.50	1	1.5	2	3	4
m	m	m	m	m	m	m	m
29	31	33	35	37	40	44	47
34	35	37	39	42	45	49	53
39	40	42	45	49	52	56	59
41	43	47	50	54	57	60	63
44	47	52	54	56	60	64	67
47	50	54	56	58	62	66	70
48	51	55	58	60	64	67	70

Given the head, $h = 50$ ft; the length, $L = 5\,280$ ft and the diam-
t; to find the velocity and quantity of discharge.
ing these values in the foregoing formula, we get

$$\sqrt{\frac{d \times h}{L + 54\,d}} = \sqrt{\frac{2 \times 50}{5\,280 + 108}} = \sqrt{\frac{100}{5\,388}} = 0.136$$

ın headed $\sqrt{\dfrac{hd}{L + 54\,d}}$ find 0.10, which is the value nearest to 0.136, along this line until column headed 2 is reached; then read 62 as of coefficient m.

$= 62 \times 0.136 = 8.432$ ft per sec, the velocity required.

d the discharge in cubic feet per second, multiply this velocity by oss-section of pipe in square feet.

ʒ.1416 $\times (1)^2 \times 8.432 = 26.49$ cu ft per sec.

here are 7.48 gal in a cubic foot, the discharge in gallons per second = '.48 = 198.2.

bove formula is only an approximation, since the flow is modified by ›ints, incrustations, etc.

ıd the head in feet necessary to give a stated discharge in cubic feet, formula

$$h = \frac{0.000704\,Q^2\,(L + 54\,d)}{d^5}$$

h

= total head in feet;
= total length of line in feet;
= diameter of pipe in feet;
= quantity of water in cu ft per second.

mple. Given the diameter of pipe, $d = 0.5$ ft; the length of pipe, $L =$ and the quantity of water to be discharged, $q = 3.07$ cu ft per sec; to he necessary head.

›stituting these values in the above formula, we get

$$h = \frac{0.000704 \times 9.4 \times (20 + 27)}{(0.5)^5}$$

$$= \frac{0.000704 \times 9.4 \times 47}{.0.03125} = 9.95 \text{ ft, the required head.}$$

The following formula is simpler and can be used when 54 d in relation to L is so small as to be negligible:

$$h = \frac{0.000704\, Q^2 \times L}{d^5}$$

If the pipe instead of being straight has easy curves (say with radius not less than five diameters of the pipe) either horizontal or vertical, the discharge will not be materially diminished so long as the total heads and total actual lengths of pipe remain the same, but it is advisable to make the radius as much more than five diameters as can conveniently be done.

To find the diameter of a pipe of given length to deliver a given quantity of water under a given head use the following,

$$d = 0.234 \sqrt[5]{\frac{Q^2 L}{h}}$$

in which

d = diameter of pipe in feet;
Q = cubic feet per second delivered;
L = length of line in feet;
h = head in feet.

Example. Given the head, $h = 700$ ft; the length of pipe, $L = 3\,000$ ft; the quantity to be delivered, $Q = 4$ cu ft per sec; required the diameter of pipe necessary.

Substituting these values in the foregoing formula, we get:

$$d = 0.234 \sqrt[5]{\frac{16 \times 3\,000}{700}} = 0.234 \sqrt[5]{68.57} = 0.545 \text{ ft} = 6.54 \text{ in}$$

To find the diameter of pipe required to deliver a given quantity of water with a given head.

Rule. (1) Reduce the head to feet per 100 ft; (2) from Table C, page 1385, find the discharge for the head thus obtained through a pipe 1 ft in diameter; (3) divide the required discharge by that obtained from Table C; look for the quotient in the column of Table D, page 1386, headed Ratio of Discharge, etc., and opposite it, in the adjoining columns of the table, will be found the required diameter.

Note. The use of Tables C and D gives results sufficiently correct for pipes less than 700 diameters in length.

Example. If the head of water from a reservoir to the point of delivery is 20 ft in a distance of 1 860 ft, what is the diameter of a pipe required to deliver 6 cu ft of water per second?

20 ft head in 1 860 ft = 20/18.60 ft in 100 ft, or 1.075 ft in 100

From Table C we find that the discharge per second with a head of 1.136 is 3.989 cu ft; for a head of 1.075 it would be about 3.8 cu ft. Dividing the required discharge 6, by 3.8 cu ft per sec, we have 1.58. From Table D the diameter of pipe having a ratio of discharge equal to 1.58 is found to be about 14½ in; therefore we must use a 15-in pipe to obtain the required discharge. If the required discharge is in gallons, divide by 7.5 to reduce to cubic feet. If in cubic feet per minute, divide by 60 to reduce to feet per second.

ocities and Discharges Through a Straight, Smooth Pipe One Diameter and One Mile, or 5 280 Diameters, in Length

ble E may also be used when the pressure is in feet-head of water by reducing ead in feet to pounds per square inch by Table A. Thus, if we wish the arge per minute through a ¾-in pipe 100 ft long with a head of 70 ft, we rom Table A that a head of 70 ft corresponds to a pressure of 30 lb per sq d from Table E we find the discharge through a ¾-in pipe 100 ft long with ssure of 30 lb to be 1.84 cu ft per minute.

Table F. Friction of Water in Pipes Based on Ellis and Howland's Experiments

The following table gives the friction-loss in pounds-pressure per square inch for EACH 100 ft of length in clean iron pipes of different sizes, discharging given quantities of water per minute. This friction-loss is greatly increased by bends or irregularities in the pipe.

To find the friction-head in feet, multiply by 2.3

Water-Pipe is usually tested to 300 lb pressure per square inch before delivery, and a hammer-test should be made while the pipe is under pressure. The usual length for each section of cast-iron water-pipe is from 12 ft 4 in to 12 ft 6 in, depending upon the depth of the socket, each length making approximately 12 ft of pipe when laid. Pipes from 2 to 4 in diameter are sometimes made in 8 or 9-ft lengths.

There is no standard weight of pipe for any given pressure.

Private Water-Supply. Pumps

Private Water-Supplies. The architect is frequently required to furni[sh] a water-supply for isolated buildings, and even in cities it is becoming qui[te] common for manufacturing establishments and large buildings to have th[eir] own water-supply; so that some knowledge of the various methods of su[p]plying water is requisite. Power-pumps are of so many kinds and so int[ri]cate in construction that no attempt will be made to describe them.

The Hydraulic Ram. Where a small stream of water having a fall of a [...] or more flows near the premises, an hydraulic ram may be used to great adva[ntage]

ıter for domestic purposes, or even for irrigation. The ram : momentum of the water flowing through the drive-pipe and ɔ an open tank. Water can be conveyed by a ram 13 000 ft ı ft, provided there is sufficient fall. The drive-pipe supplying : 30 or 40 ft long to give the necessary momentum. The use most economical method of pumping water, as there is no enance except for repairs, and the cost of installation, also, is

ı **of the Rife Rams** are given in the following table. The rmined from the table by multiplying the available supply of ɔr the rated amount of water a Rife ram will use, by the factor at the intersection of the line giving the fall available, for the column showing the height the water is to be elevated. The ll and 50-ft discharge is 192, and this multiplied by the supply of water per minute will give the delivery per day. This is shown by the example worked out in the corner of the table. These capacities are based on efficiencies dependent on the ratio of fall to lift. A fall of 10 ft and a lift of 50 ft give a ratio of 1 to 5, and an efficiency of 66⅔%. The efficiencies of Rife rams based on various ratios, are also given in the table.

Deep Wells and Plunger-Pumps. The common method of obtaining a private water-supply is to drive a deep well until a sufficient supply of water is obtained. The depth to which a well must be driven will, of course, depend upon the locality, and can only be determined by drillings. As the well is driven, a large wrought-iron pipe is sunk to form the casing. Casings are seldom less than 6 or more han 10 in inside diameter, 8 n being the common size. When the water-pocket has een reached, the water will usually rise and stand in the ipe several hundred feet above ts bottom, and the amount of ater that can usually be umped from such wells, without lowering the water, is practically unlimited. The cost f drilling deep wells, per foot THE CASING, differs, of course, with the strata, location and s. As a rule, however, it will average about $5 per foot for a rock and $6 per foot for a well through sand. For raising ɔpen tank a single-acting pump consisting of a working-ı operates a cylinder placed in a smaller pipe lowered into hich the water is raised, is commonly employed. The erably be placed below the water-line in the well, and is th the working-head by wooden sucker-rods. The working-

Example

With a supply of 1 400 gal per min, 10-ft fall, 50-ft elevation, No. 120 engine will deliver 268 800 gal per day.
1 400 × 192 = 268 800

* Multiply factor opposite POWER-HEAD and under PUMPING-HEAD by the number gallons per minute USED by the engine; the result will be the number of gallons DELIVERED per day.

The efficiency developed is governed by the ratio of fall to pumping-head.

The efficiency of rife rams is based on....
- 75% for a ratio of 1 to 2¼
- 70% for a ratio of 1 to 3
- 66⅔% for a ratio up to 1 to 18
- 60% for a ratio up to 1 to 23
- 50% for a ratio up to 1 to 30

ad may be operated by hand, or by a crank-rod attached to a pumping-jack, admill or engine. With a single-acting pump the plunger is raised and tered once with every revolution of the driving-wheel, the principle of oper-on being the same as in an ordinary hand suction-pump. Fig. 2 shows a nple arrangement for operating a working-head by belt-power. This is own as a deep-well power working-head. A DEEP-WELL PUMP (Fig. 2) differs m a SUCTION-PUMP in that it will raise water from any depth, whereas a suc-n-pump in practice will raise water only about 20 ft. A suction-pump may placed at any point in relation to the well, and will draw the water any sonable horizontal distance. The deep-well pump, on the other hand, must set directly over the well, but it will then deliver the water at any desired it. The amount of water pumped in a minute by any single-acting pump etermined by the diameter of the suction-cylinder, the length of stroke, and number of strokes per minute. The table following gives the capacity per ke for cylinders of different diameters, and for strokes of different lengths. ind the capacity per minute, multiply the values given in the table by the lutions per minute. The usual speed of single-acting working-heads and ping-jacks is from 25 to 30 revolutions per minute. Cylinders over 2¾ in in ieter should have a substantial iron working-head.

Air Engines. These are very extensively used for pumping water for houses, as they are absolutely safe, require little attention, and have es, springs or gauges to get out of order. They are also adapted to al-ly kind of fuel, such as coal, coke, wood, gas, or kerosene oil. They ıp from either a shallow or a deep well, but are best adapted to wells

in which the surface of the water is within 20 ft of the top of the well. Th best known hot-air engines are the Rider-Ericsson, which have been in succes ful operation for many years. These engines have capacities ranging from 1 to 3 500 gal per hour and will deliver water from 50 to 350 ft above t surface of water in the well, although the higher the water is raised the l will be the quantity delivered. The cost of these engines, with pump a tached, varies from $110 for the smallest size, having a capacity of 150 gal p hour raised 50 ft, to $540 for the largest size, having a capacity of 3 500 gal p hour raised 50 ft. The smaller size requires about 1 quart of kerosene or 3 of anthracite coal per hour. Hot-air engines should be placed close to t source of supply, and when the latter is a deep well the engine must placed so that the pump-rod will be in a vertical line above the cylinder the well, the operation of pumping being the same as that of the ordina single-acting deep-well pump. It is not practicable to DRAW water more th from 20 to 25 ft, in height, with any form of suction-pump, because of t difficulty of keeping the pipe, valve and fittings absolutely air-tight. F further information, see the catalogue of the Rider-Ericsson Engine Compan

Action of Wind and Capacities of Pumping Windmills

Velocity per hour in miles	Pressure* per square foot in pounds	Description of wind	Action of wind and windmill
3	0.045	Just perceptible.......	Windmills will not run
5	0.125	Pleasant wind.........	Might start if lightly loaded
8	0.33	Fresh breeze..........	Will start pumping
10	0.5	Average wind.........	Pumps nicely if properly load
15	1.125	Good working wind...	Does excellent work
20	2	Strong wind..........	Gives best service
25	3.125	Very strong wind......	Maximum results secured
30	4.5	Gale................	Should be furled out of wind
40	8	Storm................	Well-constructed mills an towers safe if properly erect
50	12.5	Severe storm..........	
60	18	Violent storm.........	Buildings, trees, etc., might injured
80	32	Hurricane............	Buildings, trees, etc., woul be injured
100	50	Tornado	Ruin

From the above table it will be seen that the only available winds are those blo with a velocity of from 8 to 25 miles per hour, and that a 15-mile wind can be util to the best advantage. It is therefore advisable to LOAD a windmill for a 15-mile w It then starts pumping in an 8-mile wind, does excellent work in a 15-mile wind reaches the maximum results in a 25-mile wind.

* The pressures per square foot in pounds will vary slightly from the values g according to the formula which is used to obtain such pressures. See, also, Cha XXVII, pages 1052-3, Chapter XXX, page 1199, and page 1717.

Windmills. In the country and on large suburban estates, windmills extensively used for pumping water. Aside from the noise of operation, only objection to the windmill, where it can be used, is the irregularity o supply, but with a large storage-tank this is not a serious objection when for domestic purposes only. Professor Thurston says, regarding windm "In estimating the capacity, a working-day of eight hours is assumed, but

iachine, when used for pumping, may actually do its work twenty-four hours a ay for days, weeks, and even months together, whenever the wind is stiff enough) turn it. It costs for work done only one-half or one-third as much as steam, ot-air, or gas-engines of similar power." The action of wind of different elocities, the pressure per square foot of sail-surface and its relation to the umping capacity of pumps can be found in the following table, compiled by airbanks, Morse & Company.

The windmill operates the plunger in the well, the process of pumping being e same as that of the single-acting pumps described above. The following ble of capacity was prepared by Alfred R. Wolff, and is sufficiently accurate r all practical purposes:

Capacity of the Windmill

Desig-ation of mill wheel, ft	Velocity of wind in miles per hour	Revolutions of wheel per minute	Gallons of water raised per minute to an elevation of						Equivalent actual useful h.p. developed
			25 ft	50 ft	75 ft	100 ft	150 ft	200 ft	
8½	16	40 to 50	6.192	3.016	....	....	....	....	0.04
10	16	35 to 40	19.179	9.563	6.638	4.750	....	....	0.12
12	16	30 to 35	33.941	17.952	11.851	8.435	5.680	....	0.21
14	16	28 to 35	45.139	22.569	15.304	11.246	7.807	4.998	0.28
16	16	25 to 30	64.600	31.654	19.542	16.150	9 771	8.075	0.41
18	16	22 to 25	97.682	52.165	32.513	24.421	17.485	12.211	0.61
20	16	20 to 22	124.950	63.750	40.800	31.248	19.284	15.938	0.78
25	16	16 to 18	212.381	106.964	71.604	49.725	37.349	26.741	1.34

The horse-power of windmills of the best construction is proportional to the ares of their diameters and inversely as their velocities; for example, a 10-ft in a 16-mile breeze will develop 0.15 horse-power at 65 revolutions per min-; and with the same breeze:

a 20-ft mill, at 40 revolutions per minute, 1 horse-power;
a 25-ft mill, at 35 revolutions per minute, 1¾ horse-power;
a 30-ft mill, at 28 revolutions per minute, 3½ horse-power.

he wheels of very few windmills are larger than 25 ft in diameter. There no pumps which will enable the user of a windmill to utilize the increased er obtained from winds of high velocity, so that in practice the amount of er pumped by windmills in high winds is but little more than is pumped by same mills in winds having velocities of from 12 to 18 miles per hour. For reason it is customary to regulate windmills to govern at about 25 miles an . Theoretically the increase in power from increased velocity of wind is equal ne square of its proportional velocity; as, for example, the 25-ft mill rated e for a 16-mile wind will, with a 32-mile wind, have its horse-power increased × 1¾ = 7 horse-power. A windmill "will run and produce work in an 8- breeze." Windmills have also been used for the generating and storage ectricity for small lighting-plants.*

r-Lift Process. Compressed air is now being used to an increasing extent aising water from artesian wells. The process in general consists of sub- ing a discharge-pipe in a closed well, with a smaller pipe inside delivering

* See Kent's Mechanical Engineers' Pocket-Book.

compressed air into it at the bottom. The compressed air by its inherent e pansive force lifts a column of mingled air and water which is conveyed to a open tank, to permit of the escape of the air. If desired the water may then conveyed by gravity into a series of closed tanks, and forced by air-pressure different parts of a building, the only machinery required being an air-co pressor and power for driving it The slip of the bubble constitutes the ch loss of energy in the air-lift. The method of piping a well differs according its general conditions and the quantity of water to be pumped. "No two we are alike, and consequently the method of piping which might be applied one would be unsuited to another." Information as to the best method piping any particular well may be obtained from the Ingersoll-Sergeant Dr Company.

Advantages of the Air-Lift Process. From two to six times as much wa may be obtained from a given diameter of well as with any other known syste because there are no valves, cylinders, or rods to hinder the rapid discharge water. One air-compressor operates any number of wells, which may be a distance apart so as not to affect one another. There is nothing outside t engine-room to look after or wear out. Nothing but common pipe in the wel Sand or gravel does no harm. The COST of raising 1 000 gal of water by t method, including fuel, labor, oil, interest on cost of well, boiler, compress foundations, pipes, real estate, erection and taxes, including 15% for dep ciation, runs from 2½ cts down to ¼ ct, according to the size of the pla height of lift, and other local conditions. With the average outfit of mediu or small size, it is usually under 1¼ cts.* The air-lift process is now exte sively used in ice-works, breweries, cold-storage houses, textile mills, dye-wor etc., and a great variety of industrial plants, and for the water-supply quite a number of the smaller cities. In Newark, N. J., pumps of this ty are at work having a total capacity of 1 000 000 gal daily, lifting water fro three 8-in artesian wells.†

Pneumatic Water-Supply Systems. The pneumatic system of supplyi water to buildings is used extensively in buildings and institutions remote fro public water-supplies. With the pneumatic system, instead of an open el vated tank, a closed water-tight tank of iron or steel is used, and this tank m be located at any level, for the water is forced from it by means of compress air confined in the top of the tank. This fact makes it possible to bury the ta in the ground below the frost-line, away from the heat of the sun, and where t water will have an almost uniform temperature the year round. The water protected from possible contamination from insects, rats, birds, dust, or oth agencies, while the tank takes up no valuable space above ground, imposes weight upon the attic-floor of a building, and does not disfigure the landsca The principle of operation is this: Air is compressible, while water is not. then, water is pumped into a closed tank at the bottom, it will trap the a within, and the more water pumped in, the greater the compression of the a The elasticity of the air, then, will force the water out again, whenever a fauce opened, and the water will continue to flow as long as the air is under sufficient pr sure in the tank. In practice the air would become absorbed by the water in t tank, and in a short time become exhausted, if it were not supplied as fast as us This is accomplished by injecting a proportionate amount of air with each stro of the pump, by means of a SNIFTER-VALVE air-compressor, or other device. connections to the tank are taken from the bottom, to prevent the escape of which would occur if the connections were taken from the top of the tank.

*. Ingersoll-Rand Drill Company, St Louis, Mo. † Kent.

Horse-Power Required to Raise Water to Different Heights

General Principles. The power required to raise a certain quantity of water to certain height varies directly with the quantity to be raised, and also with the eight. For instance, it requires twice as much power to raise 200 gal per minute) ft high as it does to raise 100 gal to the same height and in the same time; and to ise 100 gal 20 ft high requires twice as much power as it does to raise 100 gal 10 high. To find the theoretical horse-power necessary to elevate water to a given ight, multiply the number of gallons per minute by 8.335, the weight of 1 gal, d this result by the total number of feet the water is raised, that is, from the rface of the water to the highest point to which the water is raised, and the sult gives the power in foot-pounds; divide by 33 000, and the quotient is e horse-power. To the theoretical power a liberal allowance must be made r the inefficiency of the pump. For a cylinder-pump add from 75 to 100%. the actual height to which the water is to be raised add the friction-loss in t, given in Table F, page 1388, when the discharge is to be piped any distance.

Example. Find the theoretical horse-power required to raise 100 gal per nute 120 ft high, through a 3-in pipe, 200 ft long.

Solution. From Table F, the friction-head for 100 gal per min in a 3-in pipe,) ft long, is 1.31 × 2.3 or 3 ft. For 200 ft it will be 6 ft, which, added to 120, es 126 ft for the height. Then theoretical horse-power = 100 × 8.35 × 126/ 000 = 3.2 h.p. The actual horse-power required will probably vary from o 6, according to the efficiency of the pump. The mistake of using too ill a discharge-pipe can easily be seen from Table F. For instance, if attempted to force 100 gal per minute through 100 ft of 2-in pipe, back-pressure would be equivalent to raising the water 22 ft high. The used would be correspondingly increased. Right-angle turns are to be ided, as the friction is very materially increased, being practically equal to friction of 25 ft of straight pipe.

Table of Effective Fire-Streams

Jsing 100 ft of 2½-in ordinary best-quality rubber-lined hose between nozzle and hydrant or pump

e—Streams. The following is an extract from a paper read by John reeman at a meeting of the New England Waterworks Association, ed Some Experiments and Practical Tables Relating to Fire-Streams,

"When unlined linen hose is used the friction or pressure-loss is from 8 t
60%, increasing with the pressure. This kind of hose is best for inside use i
short lengths. Mill-hose is better than unlined linen hose for long length
but ordinarily the best quality of smooth rubber-lined hose is superior to th
mill-hose, having less frictional resistance. The ring-nozzle is inferior to th
smooth nozzle and actually delivers less water than the smooth nozzle. Fo
instance, the 7/8-in ring-nozzle discharges the same quantity of water as
3/4-in smooth nozzle, and a 1-in ring-nozzle the same as a 7/8-in smooth nozzl
Two hundred and fifty gallons per minute is a good standard fire-stream a
80-lb pressure at the hydrant; 100-lb pressure should not be exceeded excep
for very high buildings or lengths of hose exceeding 300 ft."

Notes on the Construction of Cylindrical Wooden Tanks*

Material should be either cedar, cypress, juniper, fir, yellow pine, or whit
pine, free from imperfections and thoroughly air-dry. Clear Louisiana re
Gulf cypress makes the most durable tanks.

Staves and Bottom of tanks of greater capacities than 15 000 gal should b
made of 2½-in, dressed to about 2¼ in, stock for tanks 12 ft and not exceedin
16 ft diameter or 16 ft deep. For larger tanks 3-in, dressed to about 2¾ i
stock should be used. For smaller tanks 2-in stock may be used. Stave
should be connected about one-third the distance from the top by a ⅝-i
dowel to hold them in position during erection. The bottom planks should b
dressed on four sides, and the edges of each plank should be bored with hol
not over 3 ft apart for ⅝-in dowels.

Taper. The batter to each side should not be less than ¼ in nor more tha
½ in per ft.

Hoops should be of ROUND wrought iron or mild steel of good quality. Wrough
iron is preferable because it does not rust as easily as steel. There should be n
welds in any of the hoops. Where more than one length of iron is necessar
lugs should be used to make the joints; and when more than one piece is necessa
the several pieces constituting one hoop should be tied together in preparing f
shipment. Hoops for fire-tanks should be of such size and spacing that the stre
in no hoop will exceed 12 500 lb per sq in when computed from the area at ro
of thread. For general purposes, a stress of 15 000 lb per sq in is permissibl
On acccount of the swelling of the bottom planks, the hoops near the botto
may be subjected to a stress greater than that due to the water-pressure alon
additional hoops, therefore, should be provided. For tanks up to 20 ft in diam
eter, one hoop of the size used next above it should be placed around the botto
opposite the croze and not counted upon as withstanding any water-pressur
For tanks 20 ft or more in diameter, two hoops, as above, should be use
Hoops with UPSET ends must not be used. The top hoop should be plac
within 2 in of the top of staves, so that the overflow-pipe may be inserted as hi
as possible. Hoops should be so placed that the lugs will not be in a vertic
line. No hoop should be less than ¾ in in diameter. All should be clean
of mill-scale and rust and painted one coat of red lead, lampblack and boiled
before erecting.

Note. The strength of a tank depends chiefly on its hoops. Round hoo
are specified because they do not rust rapidly; a slight amount of rust do

* These notes have been condensed from specifications published by the Inspecti
Department of the Factory Mutual Fire Insurance Company, 31 Milk Street, Boston;
most excellent pamphlet.

not have the same weakening effect as on a flat hoop, and round hoops are not likely to burst when the tank swells, as they will sink into the wood.

Spacing of Hoops. The hoops should be spaced so that each one will have the same stress per square inch, and no space should be greater than 21 in. To meet this requirement the hoops must be spaced quite close together at the bottom, the space between them gradually increasing towards the top.

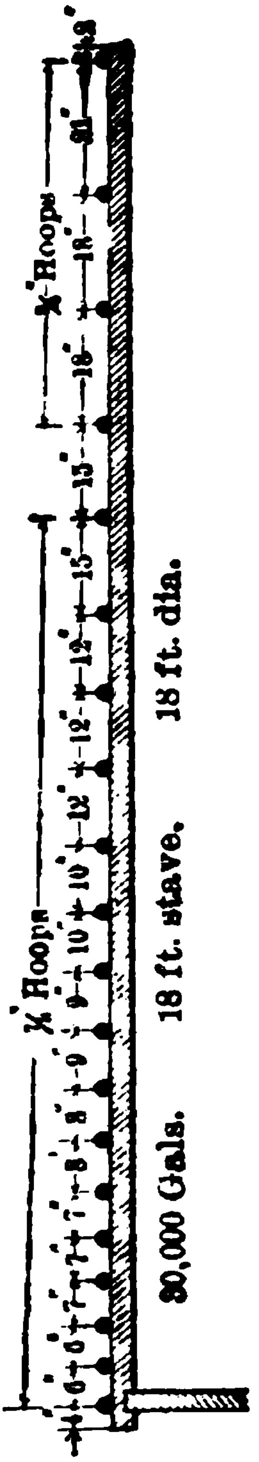

Fig. 4. Lug for Tank-hoops

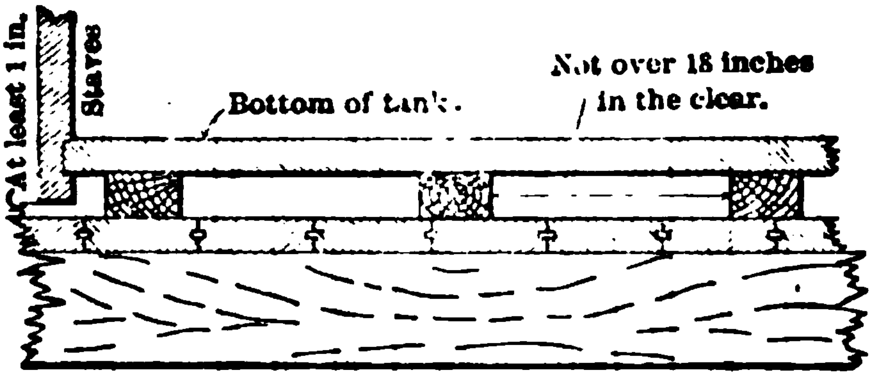

Fig. 5. Support for Bottom of Tank

Fig. 3 shows the proper spacing of hoops for a tank 18 ft in diameter, with 18-ft staves. The spacing for seven other sizes of tanks is given in the pamphlet referred to. It may be computed by the following formula:

$$\text{Spacing of hoops in inches} = \frac{\text{strength}}{2.6 \times \text{diameter in feet} \times H}$$

For strength of a ¾-in rod use 3 750; of a ⅞-in rod, 5 250; of a 1-in rod, 6 875; and of a 1⅛-in rod, 8 625.

H is the distance from surface of the water to center of hoop in feet.

Example. How far apart should 1-in hoops be placed, at 15 ft 2 in from top of tank, on a tank 20 ft diameter?

Solution. $$\text{Spacing} = \frac{6\,875}{2.6 \times 20 \times 15} = 8\tfrac{3}{4}\text{ in}$$

. 3. Diagram
f Hoop-spacing
r Tanks

Lugs should be as strong as the hoops. A lug similar to Fig. 4 is simple and fulfils the requirement for strength. Malleable lugs are required.

Support. The weight of the tank should be supported entirely from its tom; and in no event should any weight come on the bottom of the staves. e planks upon which the tank-bottom rests should cover at least one-fifth area of the bottom, should be not over 18 in apart, and of such thickness t the bottom of the staves will be at least 1 in from the floor (see Fig. 5).

he Discharge-Pipe should preferably leave the bottom of the tank at its ter and extend up inside of the tank 4 in, to allow the sediment to collect he bottom of the tank.

The Overflow-Pipe should be placed as near the top of the tank as possible, discharging either through side or bottom, as may be desired. An overflow is much to be preferred to a telltale, as the latter is liable to get out of order.

Heating. Tanks of moderate size need to be provided with some means to prevent freezing. When a tank is in an enclosed room, as in a mill-tower, the best method is to keep the room warm by a coil of steam-pipe with a return to the boiler-room. A covered tank out of doors may often be similarly heated by placing the steam-pipe in the bottom of the tank. With a tank located on a high trestle, or at a distance from the steam-supply, it is often impracticable to arrange a return-pipe. In this case steam may be blown directly into the water in the tank. A 1-in pipe is generally sufficient for this purpose. It should be carried to the top of the tank and there bend over and dip downwards, so that its outlet is about 1 ft below the high-water line. A check-valve should be placed in this steam-pipe, near its point of discharge, to prevent water being drawn back by siphon-action when the steam is shut off. The water in fire-tanks must be kept from freezing by means of a water-heater which either heats a coil in the tank, or circulates a current of water through the tank.

⅞ in. horizontal nailing strips

⅞ Thick ... ad around each box except outside, grooved sheathing.

Fig. 6. Method of Frostproofing Pipes

Frostproofing for Pipes. The discharge-pipe from a tank on a trestle, or from one elevated above a roof, must be protected from freezing. The common practice is to enclose the pipe in a double, triple, or quadruple box made of boards and tarred paper, as shown in Fig. 6. If steam is supplied to the tank, the steam-pipe is carried inside the box. In New England, New York State and Canada the quadruple boxing is generally used, whereas in the milder regions to the south triple or double boxing is used. The boxing should always be carried down into the ground below the frost-line, and a good tight joint made at the underside of the tank.

Covers. For economy in heating and to prevent birds, leaves, etc., from getting into the water, all out-of-door tanks should be covered. A double cover is recommended consisting of a tight flat cover made of matched boards supported by joists which span the top of the tank, and above this a shingled conical roof. To prevent the covering from being blown off, it should be firmly fastened to the top of the tank by straps of iron. In order to keep out the wind particular attention should be given to making a tight joint where the roof rests on the top of the staves.

Scuttles should be arranged in both the conical and flat covers to give access to the inside of the tank and a substantial, permanent ladder erected to give easy access to the top of the tank.

Dimensions of Tanks of Standard Sizes

Approximate net capacity, gal	Size. Outside dimensions: Average diameter, ft	in	Length of stave, ft	Thickness of lumber after being machined: Staves, in	Bottom, in	 A, in	B, in	C, in	Hoops: Number of	Size, in

Pumps for Fire-Streams. The dimensions of steam-pumps for fire-protection in buildings, approved by the Board of Underwriters, can be found in the following table.

Underwriter Steam Fire-Pumps

Rated capacity, gal per min	Size in inches: Diameter of steam-piston, in	Diameter of water-plunger, in	Length of stroke, in	Boiler h.p. required, A.S.M.E. standard, h.p.	Size in inches: Suction-pipe, in	Discharge-pipe, in	Steam supply-pipe, in	Steam exhaust-pipe, in	Relief-valve, in	Piston-rod, in	Valve-rod, in	Over-all dimensions of largest pump of given capacity: Length, ft	in	Width, ft	in	Height, ft	in	Proper capacity for priming-tank, gal
500	14 14 16	7 7¼ 8	12 12 10	80	8	6	3	4	3	2	1	9	⅛	5	2	7	5	250
750	16 16	9 9¼	12 12	115	10	7	3½	4	3½	2¼	1⅛	9	5	5	2	8	0	375
1000	18 18½	10 10½	12 10	150	12	8	4	5	4	2⅜	1⅛	10	8	5	7½	8	10	500
1500	20	12	16	200	14	10	5	6	5	2½	1¼	12	5	5	7	8	11	750

The capacities given in last column are desirable; but in case the suction-pipe is short and the lift low, a tank of not less than one-half the capacity stated may sometimes be used.

Notes on Steel Tanks *

Steel Tanks of sizes commonly used for fire-protection cost from 40 to 100% more than wooden tanks. The additional cost for large tanks is relatively less than for small tanks. A steel tank of about 40 000-gal capacity or over can be erected on a steel trestle at about the same cost as a wooden tank, since a saving can be made in the cost of supports by making a hemispherical or conical bottom to the steel tank and supporting the tank directly on the legs of the trestle, thus saving the expense of horizontal supporting beams. A steel tank is superior to a wooden tank for the following reasons: (1) It will last for an indefinite time if KEPT THOROUGHLY PAINTED inside and out, whereas a wooden tank will have to be replaced in from twelve to thirty years, usually in about fifteen years; (2) it will be absolutely tight when once well erected and properly cared for, whereas a wooden tank will shrink and leak if the water gets low; (3) it will not be at all likely to burst suddenly, if originally correctly designed, even if painting is neglected, for experience shows that a few spots will first rust through and thus show the weak condition by small leaks, whereas a wooden tank, if neglected, may burst its hoops suddenly and cause serious damage. The objections to steel tanks are that: (1) They require skilled boiler-makers to erect them, thus adding considerable to the cost when erected at a distance from a boiler-shop; (2) they are more difficult to protect against freezing; (3) they give more trouble by SWEATING when placed in a mill-tower; (4) they deteriorate rapidly if painting is neglected.

Stresses in Cylindrical Tanks.† The intensities of stresses in lb per sq in found in cylindrical tanks are as follows: A tensile stress due to hydrostatic pressure at any vertical joint or section of the shell of a tank filled with water,

$$S = 62.5\,HD/(2 \times 12\,t) = 2.6\,HD/t$$

A compressive stress at any horizontal joint or section, due to the weight of the stack,

$$S = W/(\pi D \times 12\,t) = 0.026\,W/Dt$$

A stress at any horizontal joint or section, tensile on the windward side and compressive on the leeward side, due to the wind, $S_2 = 0.106\,M/D^2t$. (See Self-Sustaining Steel Chimneys, page 1376.) In the above equation, H = height of tank in ft above section considered, D = diameter in ft, t = thickness of shell in in, W = weight of tank in lb, and M = bending moment in ft-lb. The conditions for overturning from wind are most severe when the tank is empty.

Stand-Pipes were much used for storage-reservoirs at one time. They usually varied from 12 to 30 ft in diameter and from 35 to 120 ft in height. A tank built in 1889 at Greenwich, Conn., was 80 ft in diameter and 30 ft in height. Its capacity was 1 300 000 gal. A stand-pipe built in 1876 at Winona, Minn, was 4 ft in diameter by 210 ft in height. The steel cylinder was surrounded by a masonry tower. A long list of failures, mostly due to faulty design, are recorded against the stand-pipe. Because of this and the superior advantage of the elevated water-tower, few are now built. General Specifications for Elevated Steel Tanks on Towers, and for Stand-pipes (Trans. Am. Soc. C. E., Vol. 64, 1909, pages 548 to 566), and General Specifications for Steel, Water and Oil-Tanks (Proc. Am. Ry. Eng. Asso., vol. 13, 1912), are both reprinted in Ketchum's Structural Engineers' Handbook.

* Actual.

nd the capacity of pipes greater than those given, look in the table for a one-half the given size and multiply its capacity by 4, or one of one-s size and multiply its capacity by 9, etc. To find the WEIGHT of water of the given sizes, multiply the capacity in cubic feet by the weight of a oot of water at the temperature of the water in the pipe.

nd the capacity of a cylinder in U. S. gallons, multiply the length by the of the diameter and by 0.0034.

Cylindrical Vessels, Tanks, Cisterns, Etc.

Diameter in feet and inches, area in square feet, and U. S. gallons capacity for 1 ft in depth

1 gallon = 231 cu in = 0.1337 cu ft

To find weight of water in pounds at 62° F., multiply the number of gallons by 8⅓.

Example. To find number of gallons in a rectangular tank that is 7.5 ft by 10 ft., the water being 4 ft deep. Look in the extreme left-hand column for 7.5 and opposite to this in the column headed 10 read 561.04, which being multiplied by 4, the depth of water in the tank, gives 2244.2, the number of gallons required.

(a) PLUMBING AND DRAINAGE

Reliable Rules for Plumbing and Drainage. The water-supply of buildings, including the apparatus for heating water, the system of drainage and sewage, and the various fixtures connected therewith, are installed by the plumber, usually in accordance with specifications prepared by the architect and subject to municipal regulations. An efficient and safe system of plumbing is a matter of vital importance. The following may be used as a reliable guide in any locality.

EXTRACTS * FROM THE RULES AND REGULATIONS OF THE DEPARTMENT OF BUILDINGS OF THE CITY OF NEW YORK; ADOPTED APRIL 23, 1912

Definitions of Terms

(12)† The term PRIVATE SEWER is applied to main sewers that are not constructed by and under the supervision of the Department of Sewers.

(13) The term HOUSE-SEWER is applied to that part of the main drain or sewer extending from a point 2 ft outside of the outer wall of building-vault or area to its connection with public sewer, private sewer or cesspool.

(14) The term HOUSE-DRAIN is applied to that part of the main horizontal drain and its branches inside the walls of the building-vault or area and extending to and connecting with the house-sewer.

(15) The term SOIL-PIPE is applied to any vertical line of pipe extending through roof, receiving the discharge of one or more water-closets with or without other fixtures.

(16) The term WASTE-PIPE is applied to any pipe, extending through roof, receiving the discharge from any fixtures except water-closets.

(17) The term VENT-PIPE is applied to any special pipe provided to ventilate the system of piping and to prevent trap-siphonage and back-pressure.

Materials and Workmanship

Soil-Pipe and Vent-Pipe. (19) All cast-iron pipes and fittings must be uncoated, sound, cylindrical, and smooth, free from cracks, sand-holes and other defects, and of uniform thickness and of the grade known in commerce as EXTRA HEAVY.

(20) Pipe, including the hub, shall weigh not less than the following average weights per linear foot:

Diameters	Weights per linear foot, lb
2 in.	5½
3 in.	9½
4 in.	13
5 in.	17
6 in.	20
7 in.	27
8 in.	33½
10 in.	45
12 in.	54

* These numbered paragraphs, from (12) to (174), extracts from Building Regulations, unedited, except in those details which affect typographical uniformity throughout book. Editor-in-chief.

† Paragraph-numbers are the same as those in the Official Regulations. Missing numbers indicate paragraphs purposely omitted.

(22) All joints must be made with picked oakum and molten lead and be made gas-tight. Twelve (12) oz of fine, soft pig lead must be used at each joint for each inch in the diameter of the pipe.

(24) Wrought-iron and steel water-pipes, vent-pipes, waste-pipes and soil-pipes must be galvanized.

(29) All brass pipe for soil-pipes, waste-pipes, and vent-pipes and solder-nipples must be thoroughly annealed, seamless-drawn, brass tubing of standard iron-pipe gauge.

Lead Waste-Pipes. (37) The use of lead pipes is restricted to the short branches of the soil-pipes and waste-pipes, bends, traps, and roof-connections of inside leaders. SHORT BRANCHES of lead pipe shall be construed to mean not more than

8 ft of 1½-in pipe
5 ft of 2-in pipe
2 ft of 3-in pipe
2 ft of 4-in pipe

(38) All connections between lead pipes and between lead and brass or copper pipes must be made by means of WIPED solder joints.

(39) All lead waste, soil, vent, and flush-pipes must be of the best quality, known in commerce as *D*, and of not less than the following weights per linear foot:

Diameters	Weights per linear foot, lb
1¼ in (for flush-pipes only)	2½
1½ in	3
2 in	4
3 in	6
4 and 4½ in	8

(40) All lead traps and bends must be of the same weights and thicknesses as their corresponding pipe-branches. Sheet lead for roof-flashings must be 6-lb lead and must extend not less than 6 in from the pipe, and the joint made water-tight.

(41) Copper tubing when used for inside leader roof-connections must be seamless-drawn tubing not less than 22 gauge, and when used for roof-flashings must be not less than 18 gauge.

Yard, Area and Other Drains

(54) All yards, areas, and courts exceeding 15 sq ft in area must be drained into the sewer. A shaft open at the top and not exceeding 25 sq ft in area, and which cannot be connected in back of a leader, yard, court, or area drain-trap, may be drained into a publicly placed, water-supplied, properly trapped and vented slop-sink.

(59) These drains, when sewer-connected, must have connections not less than 3 in in diameter. They should be controlled by one trap, the leader-trap if possible.

Leaders

(60) Every building shall be kept provided with proper metallic gutters and rain-leaders for conducting water from all roofs in such manner as shall protect the walls and foundations of said buildings from injury. In no case shall the water from any rain-leader be allowed to flow upon the sidewalk or adjoining property, but the same shall be conducted by proper pipes to the sewer. If there be no sewer in the street upon which the buildings front, then the water

leaders shall be conducted by proper pipes below the surface of the
› the street-gutter, or may be conducted by extra-heavy cast-iron
eching cesspool located at least 20 ft from any building. No plumb-
shall discharge into a leeching cesspool.
de leaders must be made of cast iron, wrought iron, or steel, with
tions made gas-tight and water-tight by means of a heavy lead or
rn tubing wiped to a brass ferrule or nipple calked or screwed into

side leaders may be of sheet metal, but they must connect with the
by means of a cast-iron pipe extending vertically 5 ft above the

lers must be trapped with cast-iron running traps so placed as to
zing.
-water leaders must not be used as soil-pipes, waste-pipes or vent-
all any such pipe be used as a leader.

[H]ouse-Sewer, House-Drain, House-Trap and Fresh-Air Inlet

house-drain must properly connect with the house-sewer at a point
of the outer front vault or area-wall of the building. An arched or
opening in the wall must be provided for the drain to prevent
settlement.
house-drain if above the cellar-floor, must be supported at inter-
by 8-in brick piers or suspended from the floor-beams, or be other-
supported by heavy iron-pipe hangers at intervals of not more

eam-exhaust, boiler blow-off, or drip-pipe shall be connected with
in. Such pipes must first discharge into a proper condensing tank,
a proper outlet to the house-sewer outside of the building must be
low-pressure steam-systems the condensing tank may be omitted,
-connection must be otherwise as above required.
ouse-drain and house-sewer must be run as direct as possible,
at least ¼ in per ft, all changes in direction made with proper
ll connections made with Y branches and one-eighth and one-six-

use-Sewer. (74) The house-sewer and house-drain must be at
liameter where water-closets discharge into them. Where rain-
es into them, the house-sewer and house-drain up to the leader-
ust be in accordance with the following table:

Diameter of pipe, in	For a fall of ¼ in per foot, sq ft of drainage-area	For a fall of ½ in per foot, sq ft of drainage-area
3	1 200	1 500
4	2 500	3 200
5	4 500	6 000
6	8 000	10 000
7	12 400	15 600
8	18 000	22 500
9	25 000	31 500
10	41 000	59 000
12	69 000	98 000

(75) Full-size Y and T-branch fittings for hand-hole clean-outs must be provided where required on house-drain and its branches. No clean-out need be larger than 6 in in diameter.

(76) An iron running-trap must be placed on the house-drain near the wall of the house, and on the sewer-side of all connections, except a Y fitting used to receive the discharge from an automatic sewage-lift, oil-separator or a drip-pipe where one is used. If placed outside the house or below the cellar-floor it must be made accessible in a brick manhole, the walls of which must be 8 in thick, with an iron or flagstone cover. When outside the house it must never be less than 3 ft below the surface of the ground.

(79) A FRESH-AIR INLET must be connected with the house-drain just inside of the house-trap and extended to the outer air, terminating with a return-bend, with open end 1 ft above the grade at most available point, to be determined by the superintendent of buildings and shown on plans. The fresh-air inlet-pipe must be of the same diameter as the house-drain. An automatic device approved by the superintendent of buildings may be used when set in a manner satisfactory to him.

Note. The fresh-air inlet and running trap prescribed by Sections 76 and 79 are not required in many cities, and it is better to omit them where not required.

Soil-Pipes, Waste-Pipes and Vent-Pipes

(81) All main, soil, waste or vent-pipes must be of iron, steel, or brass.

(90) The diameters of soil-pipes and waste-pipes must not be less than those given in the following table:

Main soil-pipes	4 in
Main soil-pipes for water-closets on five or more floors	5 in
Branch soil-pipes	4 in
Main waste-pipes	2 in
Main waste-pipes for kitchen-sinks on five or more floors	3 in
Branch waste-pipes for laundry-tubs	1½ in
When set in ranges of three or more	2 in
Branch waste for kitchen-sinks	2 in
Branch waste for urinals	2 in
Branch waste for other fixtures	1½ in

(97) The SIZES OF VENT-PIPES throughout must not be less than the following:

For main vents, 2 in in diameter; for water-closets on three or more floors, 3 in in diameter; for other fixtures on less than seven floors, 2 in in diameter; 3-in vent-pipe will be permitted for less than nine stories; for more than eight and less than sixteen stories, 4 in in diameter; for more than fifteen and less than twenty-two stories, 5 in in diameter; for more than twenty-one stories the size of vent-pipe shall be determined by the superintendent of buildings.

For fixtures other than water-closets and slop-sinks and for more than eight stories, vent-pipes may be 1 in smaller than above stated.

Traps

(101) Every fixture must be separately trapped by a water-sealing trap placed as close to the fixture-outlet as possible and no trap shall be placed more than 2 ft from any fixture.

set of not more than three wash-trays may connect with a single trap, trap of an adjoining sink, provided both sink and tub waste-outlets same side of the waste-line and the sink is nearest the line. When so the waste-pipe from the wash-trays must be branched in below the

ie discharge from any fixture must not pass through more than one reaching the house-drain.

l earthenware traps must have approved heavy brass floor-plates cured to the branch soil-pipe and bolted to the trap-flange and the gas-tight. The use of rubber washers for floor-connections is pro- ll floor-flanges must be set in place and inspected before any water- thereon.

trap shall be placed at the foot of main soil- and waste-pipe lines.

e sizes for traps must not be less than those given in the following

ater-closets	4 in in diam.
op-sinks	2 in in diam.
itchen-sinks	2 in in diam.
ash-trays	2 in in diam.
inals	2 in in diam.
ower-baths	2 in in diam.
her fixtures	1½ in in diam.

leaders, areas, floor and other drains must be at least 3 in in diam-

Water-Closets

enement-houses, lodging-houses, factories, workshops, and all gs the entire water-closet apartment and side walls to a height e floor, except at the door, must be made water-proof with asphalt, netal, or other water-proof material as approved by the superin- ldings.

general water-closet accommodation of any building cannot be cellar nor can any water-closet be placed outside of a building, ce an existing water-closet.

sewer-connected occupied buildings there must be at least one nd there must be additional closets so that there will never be en persons per closet.

ging-houses there must be one water-closet on each floor, and more than fifteen persons on a floor, there must be one additional r every fifteen additional persons or fraction thereof.

-closets and urinals must never be connected directly with or e water-supply pipes, except when flushometer-valves are used, water-closet and urinal-cisterns and automatic water-closets erns are prohibited unless approved by the superintendent of

pper lining of water-closets and urinal-cisterns must not be lighter er.

closet flush-pipes must not be less than 1¼ in and urinal flush- ameter, and if of lead must not weigh less than 2½ lb and 2 lb h-couplings must be of full size of the pipe.

Sinks and Wash-Tubs

(147) In all houses sinks must be entirely open, on iron legs or brackets, without any enclosing woodwork.

(148) Wooden wash-tubs are prohibited, except when used in hotels, restaurants or bottling establishments for washing dishes or bottles. Cement or artificial stone tubs will not be permitted unless approved by the superintendent of buildings.

Testing the Plumbing-System

(171) The entire plumbing and draining-system within the building must be tested by the plumber, in the presence of a plumbing inspector, under a water-test. All pipes must remain uncovered in every part until they have successfully passed the test. The plumber must securely close all openings as directed by the inspector of plumbing. The use of wooden plugs for this purpose is prohibited.

(172) The water-test will be applied by closing the lower end of the main house-drain and filling the pipes to the highest opening above the roof with water. The water-test shall include at one time the house-drain and branches, all vertical and horizontal soil, waste and vent and leader-lines and all branches therefrom to point above the surface of the finished floor and beyond the finished face of walls and partitions. If the drain or any part of the system is to be tested separately, there must be a head of water at least 6 ft above all parts of the work so tested, and special provision must be made for including all joints and connections in at least one test.

(173) After the completion of the plumbing-work, in any new or altered building and before the building is occupied, a final smoke-test must be applied in the presence of the plumbing-inspector. Except that for a building not over six stories in height, a peppermint-test may be applied.

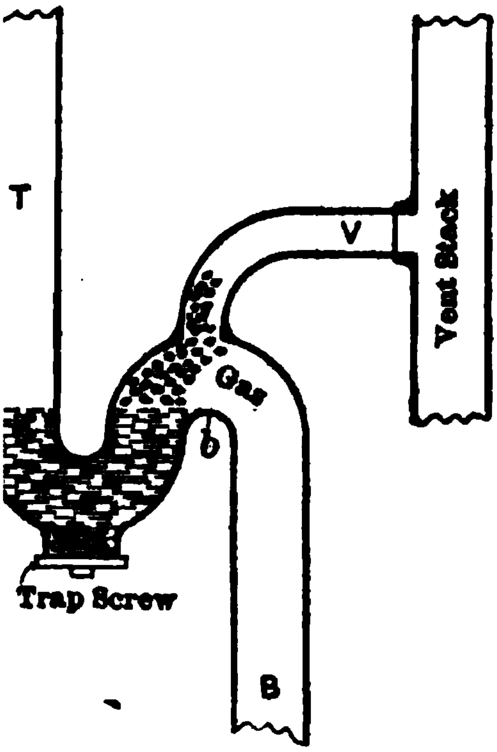
(174) The material and labor for the tests must be furnished by the plumber. Where the peppermint-test is used, 2 oz of oil of peppermint must be provided for each line up to five stories and cellar in height, and an additional ounce of oil of peppermint must be provided for each line when lines are more than five stories in height.

Traps

A trap is a device which permits the free passage of liquids through it, and also of any solid matters that may be carried by the liquid, while at the same time preventing the passage of air or gas in either direction. Traps used for plumbing purposes are shaped so that an amount of water sufficient to close the passage and prevent the passage of air will stand in them at all times. The principle of the common trap is shown in Fig. 7. The pipe *T* receives the waste from a sink or wash-basin, while the lower end *B* connects with the sewer. Sewer-gas rises in pipe *B*, but is prevented from passing to the fixture by the water which stands in the trap. The depth of water through which gas must pass to effect a passage is termed the WATER-SEAL. The water-seal in the trap, Fig. 7, is the distance *S*. All plumbing-pipes which connect with a sewerage-system require to be trapped to prevent sewer-gas from passing through them to the fixture and into the room in which the fixture is located.

Ventilation of Traps. When a considerable body of water rushes down through a pipe it forms a suction, and if the pipe is made air-tight, this suction is often sufficient to prevent enough water remaining in the trap to form a seal, thus leaving an opening for the passage of sewer-gas, as in Fig. 8. By connecting the upper bend of a trap with the outside air by means of a pipe, as at *V*, Fig.

will be stopped, and the water in the pipe *T* will not fall below the outlet at *b*. Several non-siphoning traps have been patented for of obviating the necessity of back-venting, but they are used to a ly limited extent. There are also several varieties of back-pressure



ig. 7. Water-seal of Trap

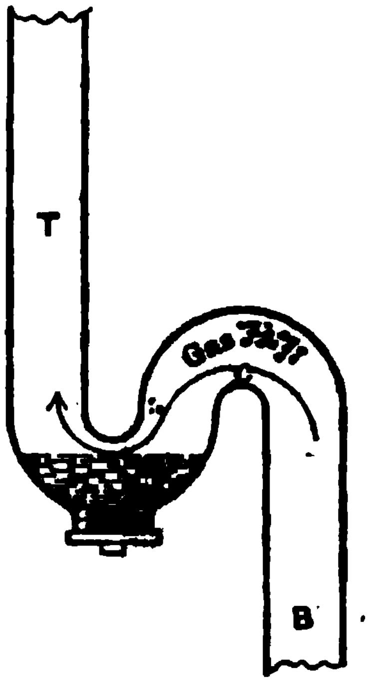


Fig. 8. Water-trap Unsealed

ed to prevent the sewage from flowing back into the house-drain. the nature of check-valves, and are used principally in seaport- tide-water might possibly force the sewage back. The more com- of lead traps used in plumbing, with their trade names, are shown

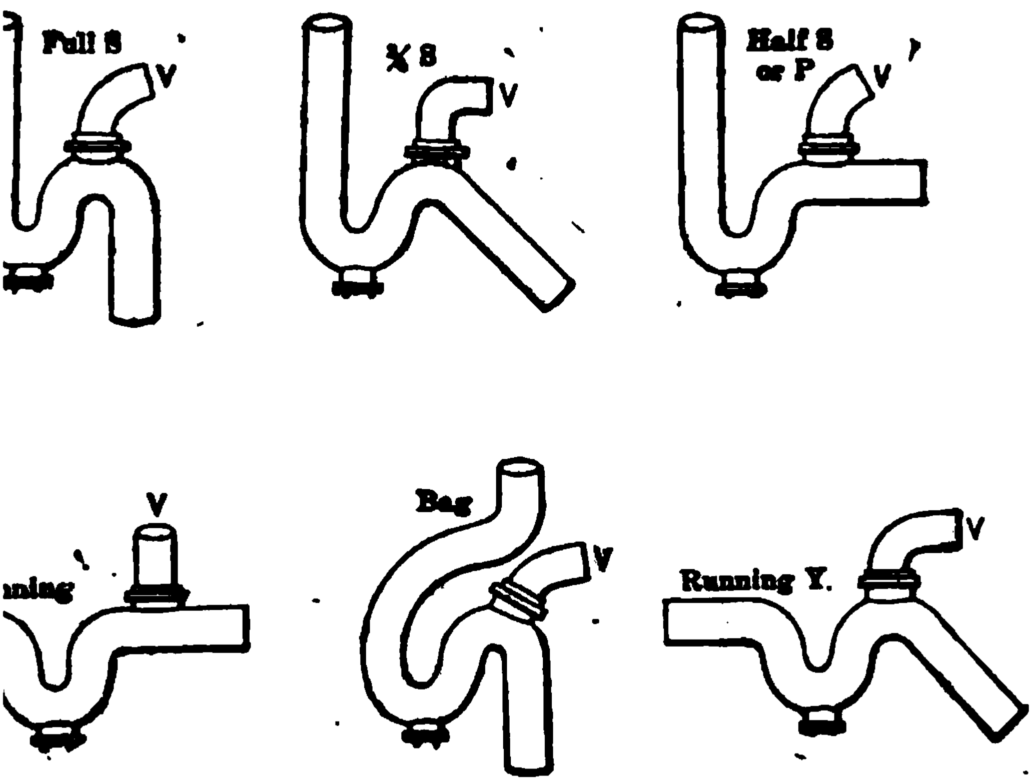

Fig. 9. Types of Traps

he same shapes are also made of cast iron. The pipes marked *V* connections. The drum-trap shown in Fig. 10 has a deeper seal own in Fig. 9, and is commonly used under kitchen-sinks, bath-tubs ys. Drum-traps are not easily siphoned, even when not vented. water-closets are commonly formed in the fixture.

Grease-Traps. The waste-water from kitchen-sinks always contains considerable grease, which if permitted to enter the soil-pipe system is liable to clog the pipes by adhering to the walls. In certain localities grease gives much more trouble than in others, due to the chemical composition of the water. In Colorado and many other places it is necessary to connect the waste from kitchen-

Fig. 10. Drum-trap

Fig. 11. Outdoor Grease-trap

sinks with a large grease-trap, which collects and holds the grease, but permits the water to pass into the sewer system. After a time the accumulated grease fills the trap and must be removed. On account of this it is desirable to use a large trap, and whenever possible it should be placed underground, just outside the house, and as near to the sink as practicable. Grease-traps to be placed underground are commonly made of 24-in vitrified drain-tile or cement pipe, and should be about 4 ft deep. They may also be built of brick in cement mortar. Fig. 11 shows a section through such a grease-trap and the inlet and outlet-pipes. When the sink is in a basement or an upper story, or when the building occupies the entire lot, the grease-trap must be placed under the sink. When so placed, a round lead trap 12 or 14 in in diameter may be used, with a large trap-screw in the top for removing the grease. Fig. 12 shows a section through such a trap and the way in which the connections should be made. A better form of grease-trap is made of cast iron. Some city ordinances require that inside grease-traps shall have a chilling-jacket for the purpose of more perfectly separating the grease and thus preventing any of it from entering the waste-pipes. To be effective, a grease-trap must have a capacity of at least twice the amount of greasy water that will be discharged into it at any one time.

Fig. 12. Lead Grease-trap

es. These may be of lead, brass, galvanized iron, tin-lined lead, Lead pipe offers the least resistance to the flow of water, is easily ny situation, and easy curves are readily made. It is generally re durable underground than galvanized-iron pipe. The grade r STRONG, is the lightest that should ever be used, and when the n from city mains, in which there is a considerable pressure, *AA*, g pipe, should be used. Galvanized-iron pipe is probably more ed than any other material for water-supply pipes in buildings, nickel-plated pipe is required, in which case brass piping is com-Brass pipe used for water-supply should be what is known as IRON-rass piping is preferable to galvanized iron or lead for conveying d is largely used in the better class of buildings. Tin-lined iron s and pipes of block tin are usually considered as offering the ance to corrosion or chemical action, and should always be used ale, beer and other liquors. Tin-lined iron pipe is made by pouring a wrought-iron pipe. While in a fluid state the tin is inseparably ron, and the result is one solid pipe composed of two metals which ORN APART. It is essentially different from iron pipe merely and immeasurably superior to iron pipe lined with a separate will become detached. Its fittings are lined with tin to match. l not injure it, rats will not gnaw it, and thieves will not cut it ot or cold water may stand in block-tin pipes and yet be drawn re and free from poison or rust. Lead-lined pipe is made in the insures delivering the water to the house just as it comes from the ged by the chemical action which often results from contact with pipe.

Drawn Benedict Nickel Tubing is used to some extent for the bing-pipes in high-class residences, office and public buildings. ite metal throughout it cannot rub or wear BRASSY or become is made in all the regular iron-pipe sizes, and necessary fittings the same metal.*

ks. Where the pressure in the street-mains is not great enough fficient volume of water for supplying the fixtures at all times, or rivate water-supply, a tank should be placed in the attic, or ele-6 ft above the highest fixture to be supplied. In some cases the lower story are supplied direct from the street mains, while those ory are supplied from a tank. The advantage of a tank is that it lly from a very small stream, and thus form a reservoir from volume can be drawn in a shorter space of time than could be t from the service-pipes. Storage-tanks should always be pro-overflow-pipe of ample size and when supplied from the street-ly should be controlled by a ball-cock and float. Storage-tanks ze are preferably made of wood lined with planished or tinned lead, zinc or galvanized iron should not be used for lining tanks er for drinking or cooking purposes, and are not as durable as hen the effect on the water need not be considered.

Tank Required will depend largely upon the character of the s supplied from the street-main in which the pressure is fairly not have a capacity exceeding 160 gal. Where the water is e tank by a windmill or hot-air engine, the tank should have a nt for a three or four days' supply at least.

information consult the Benedict & Burnham Manufacturing Company, o.

Amount of Water Required for Various Purposes. The amount of water required for household purposes has been found to be about 25 gal for each person, large or small, but waste will triple that amount sometimes. A horse will drink about 7 gal per day and a cow from 5 to 6 gal per day. A carriage requires from 9 to 16 gal for washing.

Size of Supply-Pipes. The proper diameter of supply-pipes depends upon several considerations, such as the number and size of faucets that are likely to be discharging water at the same time, the urgency of the demand, the length of the pipes and number of angles, and upon the pressure. There is no objection to having a pipe larger than is really necessary, except from the standpoint of cost. Service-pipes should always be one size larger than the tap in the street-main. The following table affords a fair guide for proportioning the supply-branches to plumbing-fixtures. If the pressure is less than 20 lb per sq in the system may be rated as LOW PRESSURE, and if above 20 lb as HIGH PRESSURE.

Supply-branches	Low pressure, in	High pressure, in
To Bath-cocks	¾ to 1	½ to ⅝
Basin-cocks	½	½
Water-closet flush-tank	½	½
Water-closet flush-valve	1¼ to 1½	1¼ to 1½
Sitz or foot-bath	½ to ¾	½
Kitchen sinks	⅝ to ¾	½ to ⅝
Pantry sinks	½	½
Slop-sinks	⅝ to ¾	½ to ⅝
Urinals	⅝ to ¾	½ to ⅝

With high-pressure systems, dwellings of five or six rooms are sometimes, for economy, supplied entirely through ¾-in pipe.

Minimum Diameter of Waste-Pipes. The following are considered as the smallest diameters allowable for waste-pipes. The diameters required in New York City are given on page 1410.

Bath and sink-wastes, 1½ in.

Basin and urinal-wastes, 1¼ in.

Wash-trays, 1½ in from each compartment, entered into 4-in drum-trap and 2-in outlet from trap.

Water-closet trap, 2½ in.

Coils of supply-pipe weigh about 200 lb; aqueduct about 90 lb; suction-pipe, 100 to 180 lb each.

Block-tin pipe is stronger for a given weight per foot than lead pipe or tin-lined lead pipe. As compared with lead pipe its strength is as 3½ to 1.

Tin-lined and lead-lined iron pipe is made with inside diameters of ½, ¾, 1, 1¼, 1½ and 2 in, and in 10-ft lengths, threaded without couplings. Tin-lined and lead-lined fittings are also made (see page 1415).

Sewer-Pipe

three kinds of sewer-pipe or drain-pipe offered in the market, (1) VITRIFIED CLAY PIPE, (2) SLIP-GLAZED CLAY PIPE and (3) CEMENT ame of the latter sufficiently indicates what it is without any de-he SLIP-GLAZED CLAY PIPE is made of what is known as FIRE-CLAY, rick clay, which retains its porosity when subjected to the most It is glazed with another kind of clay, known as SLIP, which, when eat, melts, creating a very thin glazing, and which, being A FOREIGN THE BODY OF THE PIPE, is liable to wear or scale off. SALT-GLAZED nade of a clay, which, when subjected to an intense heat, becomes ass-like. It is glazed by the vapors of salt, the salt being thrown ereby creating a vapor which unites chemically with the clay, and g, which will not scale or wear off, and is impervious to the action , steam, or any other known substance. It unites with the clay ner as to form PART OF THE BODY OF THE PIPE, and is therefore Salt-glazed pipe can only be made from clay that will vitrify, subjected to an intense heat will become a hard, compact, non- It should be borne in mind that SLIP-GLAZING is only resorted to are of such a nature that they will not vitrify.

ial of Drain-Pipes should be a hard, vitreous substance; not is would lead to the absorption of the impure contents of the drain, s actual strength to resist pressure, would be more affected by the formation of crystals in connection with certain chemical or would be more susceptible to the chemical action of the con- sewerage.

s Should be Salt-Glazed, as this requires them to be subjected intense heat than is needed for SLIP-GLAZING, and thus secures a l. Cement pipes made without metal reinforcement have not tly strong and durable to be used with confidence in any im- When reinforced with metal, however, they have ample strength, cement sewer-pipes of large diameter are used to a considerable e.

ing the diameter of house-sewers, the table on page 1409 will guide. Storm-sewers should be proportioned to the area drained. n rainfall, as shown by statistics, is about 1 in per hour, except vy storms, equal to 27 225 gal per hour for each acre, or 453 gal acre. Owing to various obstructions, not more than from 50 to fall will reach the drain within the same hour, and allowance for this fact in determining size of storm-sewer required.

Plumbing Specialties

The Kenney Flushometer. This is a gravity valve designed for flushing all water-closets, urinals and slop-sinks in a building direct from one tank situated in the attic or where most desirable, thus dispensing with the individual overhead tank. The pipe from the main tank is run down to the different floors either exposed or concealed and branches taken off from there to the flushom-

peration of the flushometer is to pull the handle forward, which ain valve off its seat, making a direct connection from the flushom- tank. After the handle is released the valve closes slowly of its against a high or low pressure. It is constructed without springs ers and closes by gravity, is built to stand the hardest service, simple in construction and operation that the same valve is used ements, the only differences in adjustment being those necessary high or low pressure. The flushometer is extensively used for ets in buildings in the Eastern States, including many large office- tories, schools, hospitals, and the better class of residences; also s and yachts.

There are few cities in which the public water-supply is not greatly wholesomeness by being filtered, and in many places filtering is cessary. The filter should be large enough so that the velocity of sing through it will be low and it should be so arranged that the can be reversed and the accumulated impurities washed into a In the country a filter suitable for rain-water may be built un- e filtering process being accomplished by beds of sand and gravel. lings, however, a portable filter located in the basement should be linary sand filter, either pressure or gravity, will clarify water of l impurities, suitable for plunge-baths, and other general uses in To provide a perfectly sterile water, however, the filter must be coagulating apparatus to automatically feed a proportionate dose o the raw water. Those so-called filters which are made to screw e of an ordinary faucet should be considered merely as strainers, hat purpose they soon become foul.

ous Water-Heaters are a great convenience for heating water wash-basins in buildings in which a constant supply of hot water l, and especially in residences where the cooking is done by gas. idrical in shape, made of nickel-plated copper, and are usually plated shelf attached to the wall close to the fixture to be supplied. in in diameter and 30 in high will heat 20 gal of water in eight ost of 1½ to 2 cts with gas at $1 per 1 000 cu ft. A large line of s made by the Instantaneous Water Heating Company, Kala- for both gas and gasoline, although gas is preferable when it he cost of heaters varies from $15 to $45, according to size.

tic Water-Heater which maintains water at any desired tem- t attention, provided the building has a supply of live steam, is B. Clow & Sons, the supply of steam being automatically regu- nostat. It will be found especially desirable in hospitals, hotels, es and public institutions. The heater is made in four sizes, of 1 500, 2 500, 4 000 and 6 500 gal per hour.

Cellar-Drainer * is a simple device for raising water from 6 to tention or power, except a supply of steam or water. It is used draining cellars, wheel-pits, furnace-pits, etc., when they are into the sewer. For such places a box or barrel is sunk so that will run into it, and the drainer is set in this receiver and the dis- to a sink or open drain. The drainer performs its functions by steam under pressure through the drainer-point or jet, thus n which draws the water from the receiver in which it is placed e-pipe, and both the jet-water and cellar-water are discharged

* Manufactured by Jas. B. Clow & Sons.

together. As long as the city water or steam passes through the drainer-pi this suction and discharge continues. The supply of water or steam is tur on or off automatically, so that there is no consumption of city water or ste except when the drainer is removing water. This drainer will operate with pressure of 15 lb or more, the heavier the pressure the greater the amount o dead water discharged. When the drainage-water does not have to be rai more than 10 ft, this is the most economical apparatus that can be used, as th amount of city water consumed is very small. The Climax Drainer is made i six sizes, costing from $25 to $160.

Sewage-Ejectment. Mechanical ejectment of sewage is resorted to in cas where the street-sewer is above the level of the area to be drained. This co dition is found principally in the subbasement-floors of tall buildings, unde ground public-comfort stations and underground passenger-stations. A syste of mechanical ejectment consists of a gravity drainage-system to a receivin tank or sump located in a water-tight pit at the lowest part of the drainag system, and a pump or compressed-air ejector to raise the sewage and dischar it into the street-sewer. There are three types of apparatus used to raise sew age to the street sewers, centrifugal pumps, piston-pumps, and compressed-a ejectors. The compressed-air ejectors, however, are commonly used owing t their numerous advantages. They are automatic and almost noiseless in opera tion, are perfectly odorless, and have but few working parts that can get ou of order. Sewage-ejectment apparatus is generally installed in duplicate s that one set may be cut out of service for cleaning or repairs, without inte rupting the drainage-service.

Plunge-Baths

An Example of the Construction and Details of a Small Plung Bath or Swimming-Bath. The following is a description, with illustration of the bath in the house of the Racquet and Tennis Club on Forty-third Stree New York City.*

"The swimming-bath has inside dimensions of 15 by 22 ft and is about 9 in total depth. It was built in a pit about 19 by 26 ft and about 8 ft deep belo the main excavation, which was blasted out of solid rock. A concrete inve 1 ft or more in thickness was laid over the bottom, serving as a footing o which the 12-in walls of common red brick were laid in cement. They we built close to the rough vertical faces of the excavation, and the spaces behin them were filled with concrete or cement mortar or were flushed with grou Then on the inner surface of the walls and on top of the concrete bottom linin a waterproofing of six layers of felt with lapped joints was mopped on with ho tar and flashed around the iron outlet-pipe, which also had a wide calked lea flange extending between the layers of felt. On the bottom of this water-pro coat an 8-in inverted segmental flat floor-arch of common brick was laid, and o its skewbacks 4-in vertical brick walls were built against the water-proofed side The bottom was then lined with vitrified white tile and the sides were faced wi English white enameled brick. The tops of the walls were coped with bevel and molded white-marble slabs which are about 2 ft above the floor-level an are surmounted at one side and one end by a low heavy rail with twisted orn mental posts, all of brass. A similar horizontal hand-rail is carried along th inside wall of the bath just above water-level and a curved brass hand-rail fastened to the wall above the narrow brick-and-marble stairs at one end. T

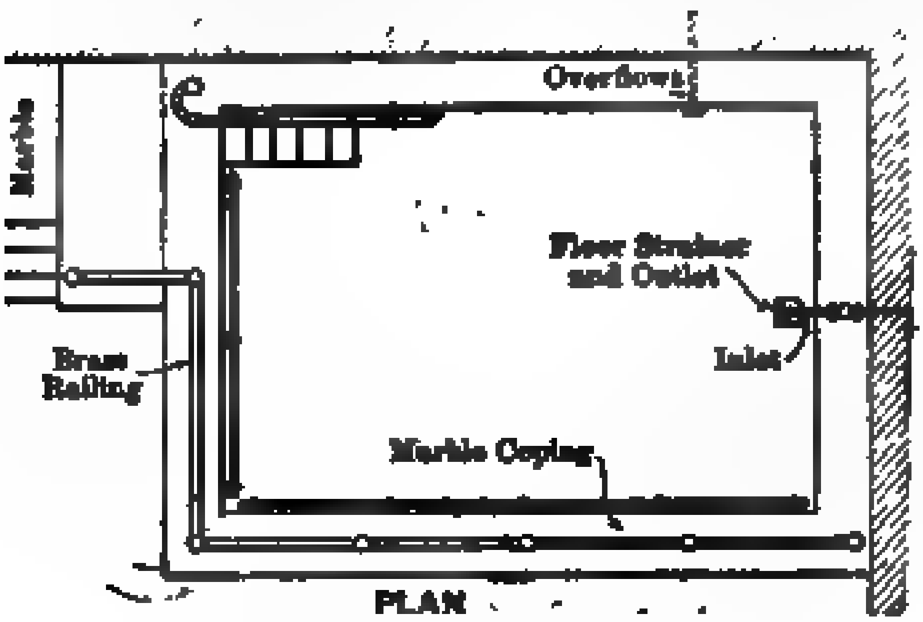
occupies one corner of the room and its elevated marble plat-
ntirely across it, forming a diving-platform which is reached by
ps. All the water-supply is filtered and it can be warmed by in-
nto the delivery-pipe at the filter. The water enters through the
end of a 2-in brass pipe projecting a foot or more through the
top of the bath and delivering a solid jet unless it is reduced by
valve or is formed into a fan-shaped cascade by means of a



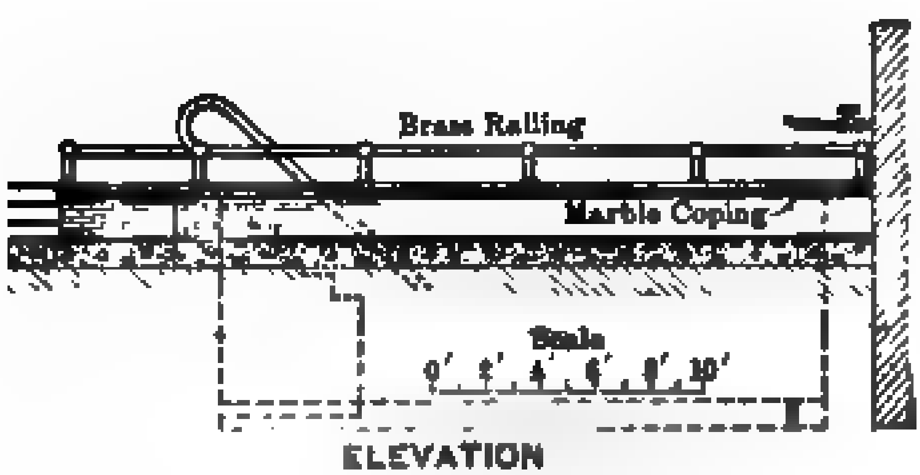


Fig. 13. Plunge-bath

hich can be screwed in the open end of the pipe When the
ed a small stream of water is constantly admitted and causes
e circulation and corresponding overflow, and the entire con-
d out and the bath cleaned every two or three days. There
s, an open one about 8 ft above the bottom and a valved one
L. W. Eidlitz was the architect of the house and the water-
e by the T. New Construction Company."

Plumbing. Figs. 14, 15 and 16 show the symbols suggested
ans and Specifications" for designating plumbing-work on plans

and details, and generally accepted for the purpose. It is just as nece to have conventional symbols to indicate plumbing-work and fixtures, as to have symbols to show-windows, doors, steps, partitions and other str

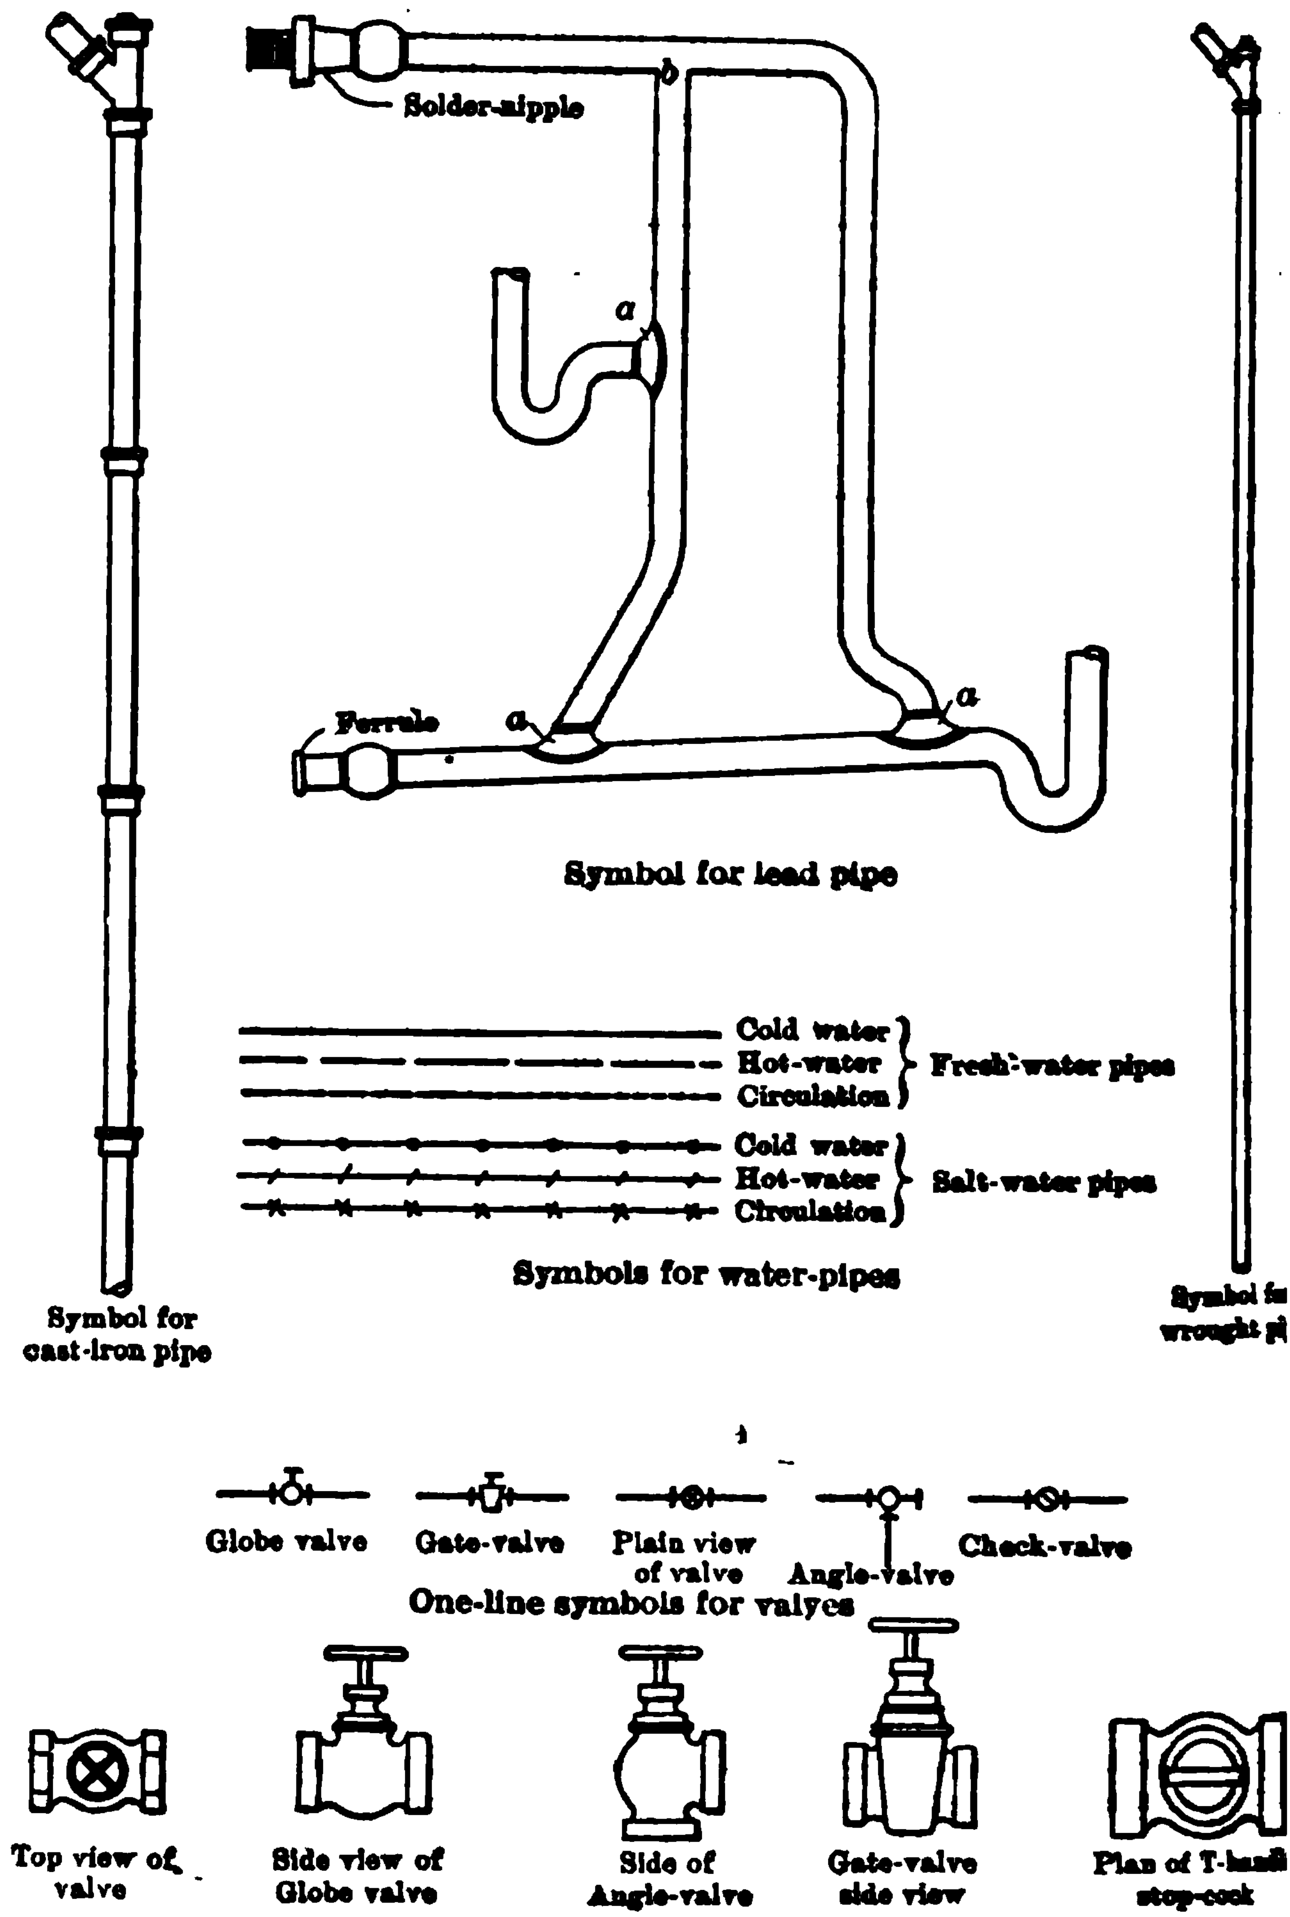

Fig. 14. Symbols for Plumbing-pipes and Valves

tural details on architectural drawings. Before these symbols became gener used there was no uniformity in the drawing of plumbing-plans, and this of standards often led to serious confusion. For instance, if plans from

were examined, the chances were that on no two of them would ave been alike. Further, plans prepared in the same office at

amount of work to be done. To avoid confusion an
standard symbols should be used.

n of Soil and Waste-Stacks. In tall buildings, provision should the soil-stacks and connections to take care of the expansion, con-ttlements, swaying and other movements of the building. This s no inconsiderable amount, in some localities the settlement alone o as much as 5 in when the foundations are not carried to bed-rock. for instance, most of the sky-scrapers which were built on com-indation-beds are out of plumb and lean far out over the plumb-building in particular leaned so that the top was 30 in outside of he foundation." Most of the earlier heavy buildings there erected foundations" are carried on jacks, and periodically jacked up as ccurs. When the building finally comes to rest, the jacks are d the walls filled in with masonry. The settlement which takes ange in such buildings from 3 to 5 in. These various move-nsion, contraction, settlement, racking out of plumb, also sway-buildings as they follow the sun in its course from East to rove destructive to steam-pipes and plumbing-pipes if provision to take care of them. Steam-pipes always have expansion-loops, y recently that the proper attention has been given to soil and and pipes; and fter as many as osets in one build-en through faulty or rigid connec-remedy is to put nts (Fig. 17) in f vent-stacks of s, and to connect all water-closets to the soil-pipes by means collapsible connections which will stretch, collapse, or stretch on collapse on the other, according to the stress to which they are These flexible fittings should be placed as close to the closets as should be used also in connection with slop-sinks and inside rain-inside rain-leaders the number of corrugations can be increased to the height of the building. Ordinary stock fittings have a ut 2 in. That is, they will stretch about 1 in and collapse 1 in. ers in tall buildings, however, greater range than that is desirable. ions would be sufficient for a rain-leader in an ordinary building ft in height; then, for taller buildings, it is well to allow an extra or each additional 100 ft or fraction thereof. The flexibility of can be seen in the accompanying illustrations of Fig. 17.

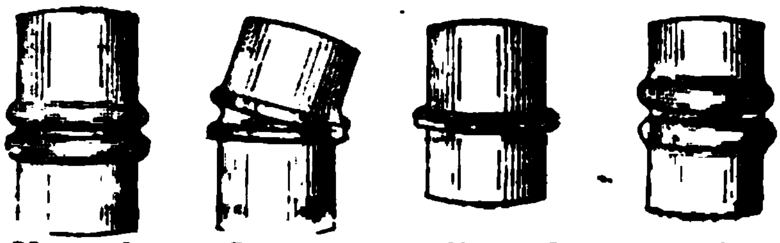

Fig. 17. Expansion-joints

in Buildings. Ninety-seven per cent of buildings erected have -construction, and the floor-joists, when they dry out, shrink. use of many thousands of closets being broken annually, and the the seal at the closet-connection of those which are not broken, re provided with a flexible floor-flange or fitting. The amount of floor-beams of different depths, can be found in the following d from information furnished by the United States Government, f Agriculture, Division of Forestry, in Bulletin No. 10. Besides of the individual tiers of joists, there is the multiple shrink-e tiers when bearing-partitions, supporting the joists at the building, rest on sills at each floor which are laid on top of tead of extending down through to the plate which supports the When the framing is properly done, there is only the shrinkage of beams to take into consideration. When improperly framed,

there might be three or four shrinkages affecting the top floor of the buildin Even though the timbers are dry and seasoned when put in, by the time th plasterers are through the joists are wet and swollen from the moisture in th plaster and from the rain which saturates the timbers before the building is e closed. It is safe to assume, therefore, that a 12-in joist will shrink almost in, and an 18-in joist about ¾ in.

Floor-Connections for Water-Closets. No water-closet can be considere sanitary which depends upon a PUTTY-JOINT, slip-joint, rigid-gasket joint c rigid connection of any kind for a seal. Improved metal-to-metal floor-flang now cost no more than rigid-gasket joints formerly did, and they are flexibl water-tight, will remain permanently tight, and protect the closets from bei broken by shrinkage or other movement of the building or piping. The onl way to get a perfectly sanitary water-closet is to specify a flexible, metal-t metal, closet floor-flange with it.

Expansion of Hot-Water Pipes. In all tall buildings expansion-loo ought to be placed in both the hot-water and the circulation-pipes, to perm the expansion and contraction of the lines without injury to the system. The loops are usually from 6 to 8 ft long, made up with elbows, and extend into th floor of the building. Generally the hot-water and circulation-pipes are su ported midway between loops so that they can expand both up and down. Th length that water-pipes will expand depends upon the degree to which they a heated, and the materials of which the pipes are made. The first of the follo ing three tables gives the expansion of cast-iron pipes, the second the expansio of wrought-iron pipes, and the third the expansion of brass pipes.

[H]ard Water for Domestic Use. In many parts of the country [T]EMPORARILY HARD, PERMANENTLY HARD or both TEMPORARILY [...]TLY HARD. This is due to the fact that in those regions the [...]k is limestone, and in percolating through the limestone the [...]riginally was soft, dissolves carbonates and sulphates of lime or [...] the rock. The solvent capacity of water for lime and magnesia [...] the water is cold than when it is hot. Therefore, deep-well [...]ne-regions is usually saturated with lime or magnesia, and when [...]-tanks or boilers the point of saturation is lowered and lime is liberated in the form of hard scale or incrustation. The effect [...]ation is to shorten the life of the boiler and decrease the efficiency [...]ile in use. It is estimated that:

1/16-in lime-scale means a loss of 13% of fuel.
1/8-in lime-scale means a loss of 22% of fuel.
1/4-in lime-scale means a loss of 38% of fuel.
3/8-in lime-scale means a loss of 50% of fuel.
1/2-in lime-scale means a loss of 60% of fuel.
3/4-in lime-scale means a loss of 91% of fuel.

[...]e probably a little high, but making due allowance, the table [...]w the loss due to the use of hard water. In the laundry the [...]ption of soap to soften hard water is a further item of expense. [...]t 1 lb of soap to soften 100 gal of moderately-hard water, [...] required for washing after the water has been softened. [...]nse, hard water forms an insoluble curd when washing which [...]larly annoying to hotel-guests; therefore, it is advisable to [...]ter for large hotel-buildings, laundries and for many indus- Permanently hard waters contain sulphates of lime or mag- [...]rily hard waters contain carbonates of lime or magnesia.

Temporarily and permanently hard waters contain both carbonates an sulphates of lime or magnesia. Temporarily hard waters are softened b adding lime-water to the raw water to remove the carbonates of lime. Th is known as the CLARK PROCESS. Permanently hard waters are softe by the PORTER PROCESS, which consists of adding soda-ash to the raw wate Stock types of apparatus are manufactured for this purpose, and may be h with capacities of any required amount.

Heating Water with Steam-Coils. The following constants will be foun convenient for proportioning steam-coils for heating water:

W = gallons of water to be heated.
$W \div 10$ = sq ft of iron pipe-coil required for exhaust-steam.
$W \div 15$ = sq ft of copper pipe-coil required for exhaust-steam.
$W \times 0.07$ = sq ft of iron pipe-coil for 5 lb pressure-steam.
$W \times 0.045$ = sq ft of copper pipe-coil for 5 lb pressure-steam.
$W \times 0.05$ = sq ft of iron pipe-coil for 25 lb steam-pressure.
$W \times 0.035$ = sq ft of copper pipe-coil for 25 lb steam-pressure.
$W \times 0.04$ = sq ft of iron pipe-coil for 50 lb steam-pressure.
$W \times 0.25$ = sq ft of copper pipe-coil required for 50 lb steam-pressure.
$W \times 0.03$ = sq ft of iron pipe-coil required for 75 lb steam-pressure.
$W \times 0.02$ = sq ft of copper pipe-coil required for 75 lb steam-pressure.

Capacity of Water-Backs. The average size of water-back having abo 110 sq in, or about ¾ sq ft of exposed surface, will heat to the ordinary tempe ature of domestic hot water, 180° F., about 21 gal of water an hour. It w heat about 17 gal of water to the boiling-point with an ordinary fire. With fire such as is used for roasting, washing, or baking, a water-back of this same si will heat about 23 gal of water to the boiling-point, or 27 gal to a temperatu of 180° F. Wrought-iron pipe heating-coils will heat from 30 to 40 gal of wat under the same conditions, and copper pipes will heat from 45 to 60 gal per ho for each square foot of surface exposed to the fire. In calculating the heati capacity of water-backs or coils, the average temperature of the water is take Thus, if water at 60° is heated to 200° F., the average temperature of the wat would be $(60 + 200) \div 2 = 130°$ F., and the range of temperature through whi it is heated would be $200 - 60 = 140°$ F.

Value of Pipe-Covering. Hot-water pipes and hot-water tanks wh uncovered lose by radiation from their surface about 13 heat-units per min per square foot of surface. To prevent this loss of heat and consequent ext consumption of coal, hot-water pipes, circulation-pipes and hot-water tanks large institutions are generally covered with some non-heat-conducting materi The value of pipe-covering is not proportional to its thickness. Sectional pip coverings average about 1⅛ in in thickness and reduce the loss by radiati about 90%. Doubling the thickness of pipe-covering saves only about anoth 5% of heat-loss. In specifying covering for pipes and boilers, therefore, a thic ness of 1⅛ in will be sufficient. Carbonate of magnesia is a very poor conduc of heat. Therefore, it is a good material for covering hot-water pipes. Carb ate of lime, on the other hand, is not a good covering material, althoug often masquerades as carbonate of magnesia. When magnesia pipe-coveri specified, therefore, it is well to require a composition containing from 80 to 9 of magnesia, and require a test to be made at the expense of the contractor, by a chemist named by the architect. The following coverings are the materials for hot-water pipes, in the order in which they are named. Nonp Cork, Magnesia, Asbestos Air-Cell and Imperial Asbestos.

(3) ILLUMINATING-GAS AND GAS-PIPING*

of Gas. Five varieties of gas are now commonly used for light-
ting, namely:

Gas, which is made by heating bituminous coal in air-tight retorts.
most common variety of gas furnished for the lighting of cities and

-Gas, which is made usually from anthracite coal and steam, and
nsively used in Eastern cities. Gas made by this process contains
han good coal-gas, and consequently does not give as bright a light,
urns perfectly in heating-burners. When used for lighting purposes
l in carbon by vaporizing a quantity of petroleum by heat and in-
to the hot gas before it leaves the generator. Pure water-gas is
as less odor than coal-gas.

l Gas is obtained from holes or wells which are drilled in the ground.
where it can be obtained it furnishes cheap light and fuel. The
btained in the hard-coal regions develops more heat per cubic foot in
any other kind of gas except acetylene. Natural gas is usually under
ure in the street-mains and house-pipes than manufactured gas.

ne-Gas. Used almost exclusively for the lighting of isolated
for public buildings in towns or cities where there is no public gas-
commonly generated on the premises. It is formed by bringing
alcium carbide in contact. Calcium carbide is produced by the
ion of coke and lime. It is now a commercial article produced in
ies and sold at a moderate price. It is a very hard substance like
has a very slight odor, will not burn or explode, and can be handled
ity with perfect safety. The fact that carbide begins to disintegrate
acetylene at the slightest touch of moisture makes it practicable to
gas in small quantities for single buildings.

Generating Acetylene-Gas. The satisfactory production of acety-
ires a generator which shall feed carbide of sufficient size and weight
l a sufficient depth under the water in the generator-chamber to
s and proper washing. The carbide-chamber must be so arranged
l that no gas can return to it to be wasted when the chamber is
ermeate the house with its smell. It must feed carbide loosely
small quantities, in order to provide for perfect coolness by free
er to all of the carbide. It must work automatically and with
ainty. Acetylene-gas to be pure must be thoroughly washed.
lene, as with any other illuminating-gas, means a discoloration of
ninished illuminating power, clogging of pipes and burners with
ther foreign matter, and smoky burners, causing blackening of
arnished and soiled woodwork and upholstery. It is now gener-
at the requirements above outlined can be attained only by a
he plunger-type. Portable generators which may be set in the
nent of any building are manufactured in great variety; it is esti-
o 000 acetylene-gas generators are now in use in the United States.
le in sizes of 5, 10, 15, 20 and up to 500-lights capacity. In all
oping carbide into water there should be a connection open from
olding receptacle to the safety-vent run out of doors from the
t is claimed that for a given degree of illumination, acetylene is
dollar gas. A large residence may be lighted for about $2.50 a

* See, also, Lighting and Illumination of Buildings, page 1437.

month. To develop the full illuminating power of the gas it is necessary to use a burner-tip having the thinnest slit obtainable, the illuminating power of the gas being about fifteen times that of coal-gas, for the same consumption. The light is a clear white, very nearly resembling sunlight in color and diffusiveness, with none of the red of the incandescent lamp, the orange of the ordinary gas-flame, or the green tone of the incandescent mantle; and it possesses the quality, unique among artificial illuminants, of reproducing even the most delicate shades of color as faithfully as sunlight. Even when used with mantle-burners, as it may be with great economy, acetylene-light presents a strong dissimilarity from ordinary gas under the same conditions. Acetylene corrodes silver and copper, but does not affect brass, iron, lead, tin, or zinc. A government specification for a complete apparatus for acetylene-gas was published in Engineering News of Feb. 4, 1904.

(5) **Gasoline-Gas** is a mixture of gasoline vapor with air. It is never piped but is generated close to the burner, and is seldom used for lighting except for street stands, and the like. It is much used for fuel, however.

Gasoline changes from the liquid to the gaseous form under ordinary atmospheric pressure, at temperatures above 40° F., the evaporation being very slow at 40°, quite rapid at 70°, and furious at 212°. If a tank containing liquid gasoline is left open to the air, the liquid will all pass away in the form of gas.

Although generally considered dangerous, it is only so when carelessly or ignorantly handled. To produce 1 000 cu ft of gas of good quality requires about 4½ gal of the best grade of gasoline. An ordinary burner consumes about 5 cu ft per hour.

Piping a House for Gas * †

General Principles and Requirements. Ordinary wrought-iron pipe, such as is used for steam or water, is suitable and proper for all kinds of gas. Galvanized malleable-iron fittings, in distinction from plain iron, are very superior. The coating of zinc inside and out effectually and permanently covers all blow-holes, makes the work solid and durable, and avoids the use of perishable cement. Before the pipe is placed in position it should be looked and blown through. It is not infrequently obstructed, and this precaution will save much damage and annoyance. What is known as gas-fitters' cement never should be used. It cracks off easily, in warm places it will melt and it can be dissolved by several different kinds of gas. Nothing but solid metals is admissible for confining gas of any kind. When pipes under floors run across floor-timbers, the latter should be cut into near their ends, or when supported on partitions, and not near the middle of spans. It is evident that a 10-in timber notched 2 in in the middle is no stronger than an 8-in timber. All branch outlet-pipes should be taken from the sides or tops of running lines. Bracket-pipes should run up from below, and not drop from above. Never drop a center pipe from the bottom of a running line. Always take such outlet from the side of the pipe. The whole system of piping must be free from low places or traps, and decline toward the main rising pipe, which should run up in a partition as near the center of the building as is practicable. It is obvious that where gas is distributed from the center of a building, smaller running lines of pipe will be needed than when the main pipe runs up on one end. Hence, timbers will not

* Circular issued by the Gilbert & Barker Manufacturing Company.

† See, also, Lighting and Illumination of Buildings pages 1437 to 1456.

deep cutting, and the flow of gas will be more regular and even. For eason in large buildings, more than one riser may be advisable. When ; has different heights of post, it is always better to have an in- rising pipe for each height of post, than to drop a system of piping igher to a lower post, or to grade to a low point and establish . Drip-pipes in a building should always be avoided. The whole piping should be so arranged that any condensed gas will flow back he system and into the service-pipe in the ground. All outlet-pipes so securely and rigidly fastened in position that there will be no possi- heir moving when the gas-fixtures are attached. Center pipes should solid support fastened to the floor-timbers near their tops. The pipe : securely fastened to the support to prevent lateral movement. The : must be perfectly plumb, and pass through a guide fastened near the of the timbers, which will keep them in position despite the assault s, masons and others. In the absence of express directions to the , outlets for brackets should generally be 5 ft 6 in high from the floor, at it is usual to put them 6 ft high in halls and bath-rooms. The upright ould be plumb, so that the nipples that project through the walls will be The nipples should project not more than ¾ in from the face of the g. Laths and plaster together are usually ¾ in thick; hence the should project 1½ in from the face of the studding. Drop center pipes roject 1½ in below the furring, or timbers if there is no furring, where own that there will be no stucco or centerpieces used. Where center- re to be used, or where there is a doubt whether they will be or not, e drop-pipes should be left about a foot below the furring. All pipes roperly fastened, the drop-pipe can be safely taken out and cut to the ngth when gas-fixtures are put on. Gas-pipes should never be placed on toms of floor-timbers that are to be lathed and plastered, because they ccessible in the contingency of leakage, or when alterations are desired, -fixtures are insecure. The whole system of piping should be proved to nd gas-tight under a pressure of air that will raise a column of mercury h in a glass tube. The pipes are either tight or they leak. There is no ground. If they are tight the mercury will not fall a particle. A piece r should be pasted on the glass tube, even with the mercury, to mark its while the pressure is on. The system of piping should remain under r at least a half-hour. It should be the duty of the person in charge of nstruction of the building to thoroughly inspect the system of gas-fitting; as much so as to inspect any other part of the building. He should know personal observation that the specifications are complied with. After satisfied that the mercury does not fall he should cause caps on the out- be loosened in different parts of the building, first loosening one to let ir escape, at the same time observing if the mercury falls, then tightening repeating the operation at other points. This plan will prove whether the are free from obstruction or not. When he is satisfied that the whole s properly and perfectly executed, he should give the gas-fitter a certificate t effect.

: following requirements from specifications published by the Denver Gas lectric Company are worthy of attention. Always use fittings in making ; do not bend pipe. Do not use unions in concealed work; use long screws ht-and-left couplings. Long runs of approximately horizontal pipe must nly supported at short intervals to prevent sagging.

Rules and Table for Proportioning Sizes of House-Pipes for Gas*†

Rules Governing Sizes of Gas-Pipes. The table on page 1435 is based on the well-known formula for the flow of gas through pipes. The friction, and therefore the pressure necessary to overcome the friction, increases with the quantity of gas that goes through, and as the aim of the table is to have the loss in pressure not exceed 1/10 in water-pressure in 30 ft, the size of the pipe increases in going from an extremity toward the meter, as each section has an increasing number of outlets to supply. The quantity of gas the piping may be called on to pass through is stated in terms of 3/8-in outlets, instead of cubic feet, outlets being used as a unit instead of burners, because at the time of first inspection the number of burners may not be definitely determined. In making the table, each 3/8-in outlet was assumed to require a supply of 10 cu ft per hour. In using the table observe the following rules:‡

(1) No house-riser shall be less than 3/4 in. The house-riser is considered to extend from the cellar to the ceiling of the first story. Above the ceiling the pipe must be extended of the same size as the riser, until the first branch line is taken off.

(2) No house-pipe shall be less than 3/8 in. An extension to existing piping may be made of 1/4-in pipe to supply not more than one outlet, provided said pipe is not over 6 ft long.

(3) No gas-range shall be connected with a smaller pipe than 3/4 in.

(4) In figuring out the size of pipe, always start at the extremities of the system, and work TOWARD the meter.

(5) In using the table, the lengths of pipe to be used in each case are the lengths measured from one branch or point of juncture to another, disregarding elbows or turns. Such lengths will be hereafter spoken of as SECTIONS. No change in size of pipe may be made except at branches or outlets, each section therefore being made of but one size of pipe.

(6) If any outlet is larger than 3/8 in it must be counted as more than one, in accordance with the schedule below:

Size of outlet, inches...........	1/2	3/4	1	1 1/4	1 1/2	2	2 1/2	3	[illegible]
Value in table..................	2	4	7	11	16	28	44	64	[illegible]

(7) If the exact number of outlets given cannot be found in the table, take the next larger number.

(8) If, for the number of outlets given, the exact length of the section which feeds these outlets cannot be found in the table, the next larger length, corresponding to the outlets given, must be taken to determine the size of pipe required. Thus, if there are eight outlets to be fed through 55 ft of pipe, the length next larger than 55 in the eight-outlet line in the table is 100, and as this is in the 1 1/4-in column, that size pipe would be required.

(9) For any given number of outlets, do not use a smaller size pipe than the smallest size that contains a figure in the table for that number of outlets. Thus, to feed 15 outlets, no smaller size pipe than 1 in may be used, no matter how short the section may be.

(10) In any piping-plan, in any continuous run from an extremity to the meter, there may not be used a longer length of any size pipe than found in the table for that size, as 50 ft for 3/4 in, 70 ft for 1 in, etc. If any one section would exceed the limit length, it must be made of larger pipe. Thus, 6 outlets cou[illegible]

rough 75 ft of 1-in pipe, but 1¼ in would have to be use uccessive sections work out to the same size of pipe and t exceeds the longest length in the table for that size pipe, t the meter of the next larger size. For example, if we h plied through 45 ft of pipe and these 5 and 5 more, n 30 ft of pipe, we should find by the table that 10 outlet quire 1-in pipe, and that 5 outlets through 45 ft would al as the sum of the two sections, 30 plus 45 equals 75 ft, int of 1 in that may be used in any continuous run, the one nearer the meter, must be made of 1¼-in pipe. Th

tion of the limit in length of any one size in a continuous run may also be shown as follows: Eight outlets will allow of 13 ft of ¾-in pipe in the section between the eighth and ninth outlet (counting from the extremity of the system toward the meter), provided that this 13 ft added to the total length of ¾-in pipe that may have been used between the extremity of the run and the eighth outlet does not exceed 50 ft, which, according to the table, is the greatest length of ¾ in allowable in any one branch of the system. Therefore, up to the eighth outlet, 37 ft of ¾-in pipe could have been used, and yet allow 13 ft of ¾ in to be used in the section between the eighth and ninth outlet. If more than 37 ft had been used, then the entire 13 ft between the eighth and ninth outlets would have to be of 1-in pipe.

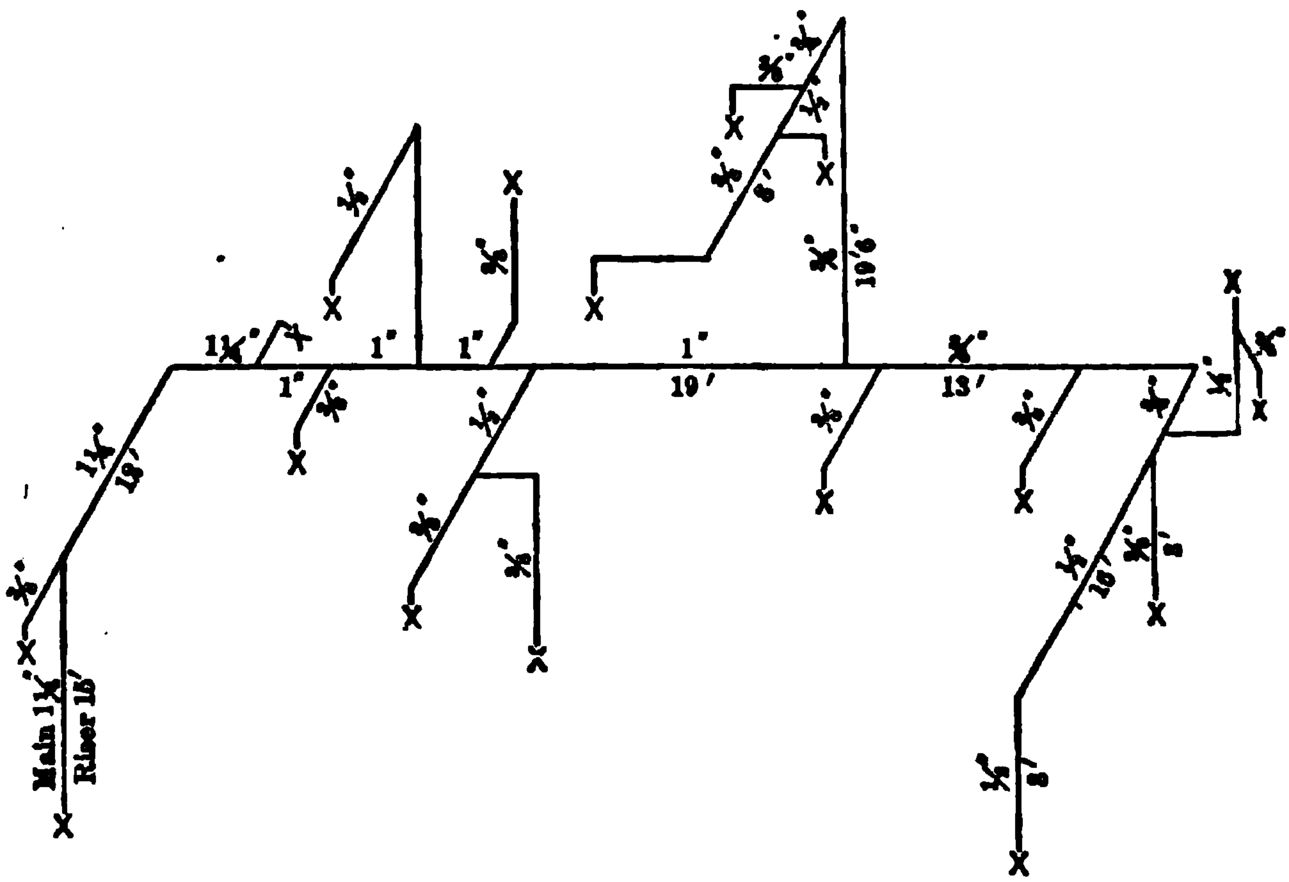

Fig. 18. Diagram of Gas-piping

(11) Never supply gas from a smaller size of pipe to a larger one. If we have 25 outlets to be supplied through 200 ft of pipe, and these 25 and 5 more, making 30 in all, through 100 ft of pipe we should find by the table that 25 outlets through 200 ft would require 2½-in pipe, and 30 outlets through 100 ft would require 2-in piping, but as under this condition a 2-in pipe would be supplying a 2½-in pipe, the 100-ft section must be made 2½ in. The sizes of pipes in Fig 18 are in accordance with the foregoing rules and the table.

LIGHTING AND ILLUMINATION OF BUILDINGS*

By

W. H. TIMBIE

ASSOCIATE PROFESSOR OF ELECTRICAL ENGINEERING, MASSACHUSETTS INSTITUTE OF TECHNOLOGY

General Principles. Objects are illuminated for the sole purpose of making them visible to the eye. The eye, then, is the natural starting-point. When passing upon the merits of any scheme of ordinary illumination, that which should mark it as a success or failure should be the general effect of the scheme upon the eye. Success should be measured largely by the degree of clearness with which the objects are perceived by the eye, as to shape and color. If certain parts of a room or street are too brilliantly lighted, objects in the dimmer portions are not perceived by the eye. If a certain side of one object is too highly illuminated, the general shape of the object is lost, as the eye does not readily perceive its more dimly lighted parts. This is because the eye automatically adjusts itself to the most brilliantly lighted area within its view, and, accordingly, is out of adjustment for perceiving the rest. We should get rid of the idea, therefore, that a light of intense brilliancy is the thing to be sought. It is, in general, highly undesirable. A room may APPEAR brilliantly LIGHTED and yet objects looked at may not be sufficiently well ILLUMINATED for reading or for working purposes. The lights APPEAR brilliant to the eye, but because they throw their strongest rays in other directions than those in which they are needed for use, they do not give efficient illumination.

Distinction between Light and Illumination. There is not only a great difference between LIGHT and ILLUMINATION, but there is a great difference between a brilliantly lighted room and a well-illuminated one. When anybody is asked whether a room is well illuminated or not, the chances are ten to one that he at once looks at the light itself. If the light appears to him to be brilliant and dazzling, he will invariably say, "Why, of course, the room is well lighted." He should first look away from the light at the objects around the room or underneath the light. If these can be seen clearly and easily, then the room is well ILLUMINATED. Afterwards he should look at the lights themselves, and if they appear soft and pleasing to his eyesight the room is well LIGHTED. A room in which the lights appear soft to the eye and yet in which the eye can distinguish objects clearly is both well lighted and well illuminated. A room in which the objects appear clear to the eye while the lights remain dazzling is well illuminated but badly lighted. A room in which the lights appear soft to the eye and the objects not clearly illuminated, is well lighted, but badly illuminated. A room in which the lights appear dazzling to the eye and the surrounding objects or those underneath appear not clear to the eyesight is both badly lighted and badly illuminated. [An] axiom in good artificial illumination is to keep the illumination of objects as [str]ong as is necessary, but the intensity or brilliancy of the lights as low as pos[sib]le. By doing the first we enable the eye to see better; by doing the second we [ena]ble the eye to feel better and suffer less from temporary discomfort or per[ma]nent injury. It is not generally understood that a light which is dazzling and [bril]liant to the eyesight may not be giving as much illumination as another [sou]rce of light which appears soft, or even dim, by comparison. Thus an open [...]light is more dazzling than an enclosed light, but is less efficient in illumi-

* See, also, Illuminating-Gas and Gas-Piping, pages 1431 to 1436.

nating a room. The problem, then, resolves itself into two parts. The first step should be to secure a kind of lamp which will cause objects to appear in their accustomed colors; that is, the colors in which they appear by sunlight. The second is to so distribute the lamps that the several illuminated surfaces receive their share of the light, and yet no bright light is thrown directly into the eyes.

Nature of Light. All space is supposed to be filled with a medium infinitely lighter than air, called ETHER. The sensation of light is experienced when certain wave-motions in this ether are transmitted to the eye. These wave-motions are called LIGHT-WAVES. Light-waves differ from one another in length and violence. The DIFFERENCE IN LENGTH causes a difference in color. Thus short waves may be blue or violet, while longer waves may be red or orange. If we have a source of light which sends out long ether-waves, we may expect a predominance of red and orange light in it. The sunlight contains waves of practically all lengths and thus is composed of all colors. The DIFFERENCE IN VIOLENCE of the waves gives rise to a difference in intensity of the light. When these light-waves strike an object, they are partly reflected and partly absorbed. Substances differ widely as to the percentage of light they absorb and the percentage they reflect. If two objects are illuminated by the same amount of light, the one which absorbs the less light and reflects the more will appear the brighter. Some objects reflect light-waves of a certain length only, and absorb all the rest. It is this property that gives color to objects. Suppose, for instance, that a piece of cloth were receiving light from the sun, all of which it absorbed except the waves of proper length to cause a sensation of green to the eye. The green waves only would then come from the cloth to the eye, all the rest being absorbed, and the cloth would appear green. If it absorbed waves of all lengths, it would appear black, because no light would be reflected from it to the eye. If now the piece of cloth, which absorbs all wave-lengths except that of green, were exposed to a source of light which was emitting all colors EXCEPT GREEN, there being no green waves to be reflected from it, the cloth in this light would appear black. Suppose a piece of cloth absorbed all colors but two, say violet and red. When light having all wave-lengths fell upon it, it would absorb all the waves except violet and red. These two, the cloth would reflect as a mixture and would appear purple. If, however, the source of light contained no violet waves, it could only reflect the red waves and appear red. This light, then, would not cause the cloth to show its normal color. So in choosing an artificial source of light, it is necessary to select one which will send out all wave-lengths, if we wish to have the different objects appear in their normal colors.

Table I. Colors of Light-Sources *

Sun (at zenith)	White (all colors)
Electric arc	Violet-white
Candle	Orange-yellow
Kerosene	Pale orange-yellow
Gas-flame	Pale orange-yellow
Welsbach (gas)	Nearly white to amber, depending upon composition of mantle
Acetylene-flame	Almost white
Carbon, incandescent	Reddish white
Tungsten or Mazda	Yellowish white
Mercury-arc	Blue-green
Moore tube (carbon dioxide)	White

* Compiled by R. F. Pierce, Welsbach Company.

Experiment has shown that no artificial light except the CO_2 Moore tube is even a remote approximation to daylight. The Welsbach white mantle gives a much whiter light than the tungsten-lamp, although neither can be said to approximate daylight.

Light-Intensity or Brilliancy. Candle-Power. The brilliancy of a source of light is stated as its CANDLE-POWER; that is, the number of standard candles to which it is equivalent. Thus an ordinary open gas-flame, consuming 5 cu ft of gas per hour, is equivalent in brilliancy to about 18 candles, and is said to have an intensity of 18 candle-power. Welsbach lamps, consuming 3 cu ft per hour, average about 75 candle-power; that is, they are equivalent to 75 candles. Since no two sources of light have the same amount of luminous surface, it is customary to rate a lamp by the number of candle-power per square inch of its apparent (or projected) surface. Thus an ordinary candle-flame has about ⅙ sq in of area, and its intensity would be rated as 3 candle-power per square inch; that is, the candle-power it would have if its area consisted of exactly 1 sq in. This is often called the INTRINSIC BRILLIANCY of a light-source.*

Table II. Accepted Values of Intrinsic Brilliancy for Various Light-Sources now in Use *

Light-Source	Candle-power per sq in
Moore tube	0.3–1.75
Frosted electric incandescent-lamp	2–5
Candle	3–4
Gas-flame	3–8
Oil-lamp	3–8
Cooper-Hewitt lamp	17
Welsbach gas-mantle	20–50
Acetylene-burner	75–100
Enclosed alternating-current arc-lamp	75–200
Enclosed direct-current arc-lamp	100–500
Incandescent lamps:	
Carbon, 3.5 watts per candle	375
Carbon, 3.1 watts per candle	480
Gem, 2.5 watts per candle	625
Tantalum, 2.0 watts per candle	750
Mazda or tungsten 1.25 watts per candle	875
Mazda or tungsten, 1.0 watt per candle	1 000
Nernst, 1.5 watts per candle	2 200
Sun, on horizon	2 000
Flaming arc-lamp	5 000
Mazda, nitrogen-filled	7 700
Open arc-lamp	10 000–50 000
Open arc-crater	200 000
Sun, 30° above horizon	500 000
Sun, at zenith	600 000

* E. B. Rowe, Holophane Works.

Intensity of Illumination. Foot-Candle. The extent to which a surface is illuminated is measured in FOOT-CANDLES. A surface has 1 foot-candle illumi-

* The total amount of light given out by a light-source is measured in LUMENS. For definition and use of this term see any standard book on illumination.

nation when it is placed, at right-angles to the light-rays, 1 ft away from a light of 1 candle-power intensity. Thus a paper placed 1 ft away from a 16-candle-power incandescent lamp would be illuminated to 16 foot-candles.

Law of Inverse Squares. The farther away from the light the above paper is held the less the illumination. But if it were held 2 ft away, that is, twice as far as stated above, it would not have one-half the illumination. The illumination which an object receives varies inversely as the square of the distance from the source. Thus, in this example the paper would receive one-fourth as much illumination, or 4 foot-candles. If it were held 3 ft away, it would be illuminated by one-ninth of 16, or 1.6 foot-candles.

Rule. To find the intensity of illumination on any surface, at right-angles to light-rays, divide the CANDLE-POWER of the lamp by the SQUARE of the distance in FEET. The result will be FOOT-CANDLE illumination. This is called the LAW OF INVERSE SQUARES. Accordingly, an unshaded 32-candle-power lamp will illuminate a surface facing it squarely and 1 ft away from it with an intensity of 32 foot-candles, but a surface 4 ft away, with only $32/4^2$, or 2 foot-candles.

Candle-Power and Foot-Candle. Careful distinction should be made between CANDLE-POWER and FOOT-CANDLE. CANDLE-POWER is the measure of the intensity of a source of light. The FOOT-CANDLE is the measure of the intensity of illumination of some surface upon which the light falls.

Example 1. What is the illumination on a surface 5 ft from a 32-candle-power lamp?

Solution. $\frac{32}{5 \times 5} = 1.28$ ft-candles.

Example 2. The illumination required on a printed page for easy reading is about 2 foot-candles. (1) How high above a reading-table should a 16-candle-power lamp be hung? (2) A 32-candle-power lamp?

Solution. $\frac{16}{x^2} = 2 \qquad x^2 = 8 \qquad x = \sqrt{8} = 2.83$ ft (1)

$\frac{32}{x^2} = 2 \qquad x^2 = 16 \qquad x = 4$ ft (2)

The Primary Function of a Lighting-Installation is to supply sufficient illumination as required by the character of the work to which the lighted space is devoted. The following table can be used in computing the amount of electric power or of gas necessary to satisfactorily illuminate the various rooms included.

Since the lower efficiencies of the indirect and semiindirect systems are largely compensated by the lower intensities required as compared to direct lighting the same watts per square foot may be allowed in either case, provided the conditions are fairly favorable to the use of the indirect and semiindirect systems namely, light-cream or yellow ceilings. The following table is based upon rooms of average proportions with light-cream, or yellow ceilings and medium walls High, narrow rooms may require about 10% more, and low, wide rooms about 10% less, energy. Similar allowances may be made for dark or light walls respectively.

Three Systems of General Illumination. To secure the proper illumination, as indicated in Table III, there are three general systems.

Table III. Amount of Gas or of Electric Power Required to Illuminate Rooms Used for Various Purposes

Class of service	* Cu ft of gas per sq ft per hour	* Watts per sq ft
Armory or drill-hall	0.02 -0.025	0.5-0.6
Auditorium	0.04 -0.05	1.0-1.3
Barber-shop	0.06 -0.07	1.5-1 7
Church (see Auditorium)	....	....

Factory (general illumination)	0.01 -0.02	2.5-0.5
Hospital (corridor)	0.016-0.02	0.4-0.5
Hospital (operating-room)	0.14 -0.15	3.5-3.9
Hotel (lobby)	0.06 -0.065	1.5-1.6
Hotel (ball-room)	0.05 -0.052	1.2-1.3
Hotel (dining-room)	0.04 -0.045	1.0-1.1
Hotel (restaurant)	0.06 -0.07	1.5-1.7
Hotel (kitchen)	0.05 -0.052	1.2-1.3
Hotel (writing-room, general illumination only)	0.052-0.06	1.3-1.5
Hotel (billiard-room, general illumination only)	0.06 -0.065	1.5-1.6
Hotel (buffet)	0.065-0.072	1.6-1.8
Library (reading-room)	0.055-0.06	1.4-1.5
Library (stacks)	0.012-0.024	0.3-0.6
Office (banking and accounting)	0.06 -0.065	1.5-1.6
Office (general)	0.052-0.06	1.3-1.5
Office (private)	0.05 -0.52	1.2-1.3
Office (stenographic)	0.06 -0.07	1.5-1.7
Residence (bedroom)	0.012	0.3
Residence (dining-room)	0.036-0.04	0.9-1.0
Residence (hall)	0.008	0.2
Residence (living-room)	0.036-0.04	0.9-1.0
Residence (music-room)	0.02 -0.025	0.5-0.6
Residence (kitchen)	0.05 -0.052	1.2-1.3
School (assembly or class-room)	0.04 -0.045	1.0-1.1
School (class-room, business colleges)	0.055-0.06	1.4-1.5
Stores (piano, furniture, haberdashery, dry-goods, automobile, clothing, cigar)	0.06 -0.07	1.5-1.7
Stores (book, shoe, hardware)	0.055-0.06	1.4-1.5
Warehouses	0.012-0.036	0.3-0.9

* These figures are based upon the use of Welsbach reflex lamps and Mazda electric lamps. For Welsbach KINETIC lamps and nitrogen-filled tungsten-lamps (type C Mazda) use about 0.6 the values in the first and second columns, respectively. Data on gas supplied by R. F. Pierce, Welsbach Company.

(1) **Direct Lighting.** A system is designated as DIRECT when more than one-half the light reaches the area to be illuminated by coming directly from the light-source, without being reflected from the ceiling or walls. This includes all systems using lamps with clear, frosted, translucent, or opalescent globes, or reflectors, in which the light is reflected downward. It is the most efficient system, was the first to be used, and is still the most common. The color of the walls or ceiling has less effect in this system than in the others.

(2) **Indirect Lighting.** A system is designated INDIRECT when all the light is thrown first on the ceiling and walls, and reflected from these to the surface to be illuminated. Any system which conceals the source of light by opaque reflectors is thus INDIRECT. Light finish must always be used on the walls and ceiling

with this system. Even then, the efficiency is usually lower than that of a direct system, but the total absence of glare and shadows and the even distribution of light make this a popular scheme in restaurants, show-rooms, etc., where decorative lighting is desired.

(3) **Semiindirect Lighting.** This system throws most of the light to the walls and ceiling, but allows a small percentage to be diffused through the reflector straight to the area to be illuminated. This system is rapidly coming into favor because apparently we have become accustomed to looking for the source of light and miss it when it is concealed as in the indirect system. The totally indirect fixtures often show up rather unpleasantly as a dark spot against a light background.* This is avoided in the semiindirect system. The slightly higher efficiency of this system is another advantage over the indirect. Any given room may usually be lighted by any one of the three systems although it is generally true that conditions are such as to make one of the three more desirable than either of the other two. The following paragraphs show in detail how each system may be worked out for a given room.

General Considerations † in Direct Lighting

Outlets and Lamps. Outlets should be located in the centers of as nearly as possible square and equal areas into which the ceiling, for the purpose of calculation, may be subdivided. The greater the number of outlets the more uniform the illumination and the greater the freedom from annoying shadows. Unless great care is used in planning the directions in which the light is received by illuminated surfaces, a disagreeable glare from glazed paper is likely to be present. The greater the height of lamps above the illuminated area, the more uniform the illumination. Figures suggestive of good practice in selection of mounting-heights are given in Table IV, page 1444.

General Considerations in Indirect and Semiindirect Lighting

Outlets and Lamps. The location of outlets should in general conform to the requirements for direct lighting, that is, at the centers of approximately square and equal areas. Since glare from glazed papers is minimized when most of the light is received from ceiling-reflection, larger and fewer units are permissible than in the case of direct lighting. The nearer to the ceiling the lamps are placed, the less uniform the illumination and, within reasonable limits, the higher the illuminating efficiency of the installation. Generally speaking, lamps should not be placed less than 2 ft from the ceiling. Aside from this, the position of a fixture should be determined by artistic considerations and reflectors selected which will direct most of the light upon the ceiling without concentrating it enough to illuminate the ceiling unevenly.

A. The Interior Colorings and Finishes.‡ (1) Ceilings especially should be of nearly white, cream, or light-buff colors to efficiently diffuse the light downward. Dark greens, reds, or blues are not advisable since the reduction in illumination caused by a green color, over a cream tint, may easily be from 30% to 60%. On the other hand, this system shows very plainly all dirt and discolorations on the ceiling, and no colors should be used that are so light as to easily show dirt, where there may not be careful cleaning.

* This unpleasant effect can sometimes be avoided by illuminating the underside of the fixture.

† By R. F. Pierce, Welsbach Company and G. S. Fobes, Macbeth-Evans Company.

‡ By G. S. Fobes, Macbeth-Evans Company.

(2) Finishes preferably should be matt, or satin, rather than glazed or varnished. From the matt ceiling-surface the maximum light will always be downward, but the varnished ceiling will reflect specularly, directing light sidewise or showing lamp-images and glare.

(3) Tints and details of decoration should be considered together with the lighting-system, so that daylight-colors and reliefs will not be reversed or distorted by colored light from artificial illuminants and shadows.

B. The Positions of Outlets and of Fixtures. (1) Semiindirect units should, if possible, be placed above the places where maximum light is wanted.

(2) Fixtures should not be so close to side walls as to cause light-spots running down across picture-moldings, etc.

(3) Outlets should be placed logically with reference to the ceiling-panels, so that the more brightly illuminated ceiling-areas will be the ones that on account of their tints, shapes, or decorations, will naturally bear emphasis. If the panels are deep (deep beams), and one outlet is in each panel, it will ordinarily be located at the center. If several panels intervene between units, the fixtures should be on the beams rather than in the panels, to prevent dark ceiling-areas in the shadows of the beams.

(4) Spacing should be such as to have the illuminated ceiling-areas overlap if the ceiling-surface is uniform.

C. The Proper Lamp and Bowl-Sizes. (1) Ordinarily the symmetrical appearance of fixtures with respect to the other interior furnishings will largely determine their sizes, although the bowls should never be so small as not to completely conceal and nearly surround the lamp-bulb.

(2) The smaller the bowl and the brighter the lamp, the less effective the semiindirect system becomes, and the more the effect approaches direct lighting.

D. Shapes and Styles of Bowls. (1) Bowls used close together or hung far from the ceiling should be of the focusing (upward) distribution, while broadly distributing bowls are better when used singly, or when fairly wide apart and close to the ceiling.

(2) Bowls too flat in shape may waste considerable light sidewise to the upper walls and therefore be inefficient.

(3) Wide open-top bowls should not be used in halls, etc., where the bare lamps are visible to the observer from above, nor on or below the level of a balcony or mezzanine.

E. Care of Fixtures. (1) The average saving in light (expressed in terms of cost of current) that results from washing once and dusting once monthly, will be from four to ten times the cost of such cleaning. Bowls often collect films of dust which are not visible and which materially reduce the efficiency both of reflection and transmission.

(2) A bowl with a dust-cap, button-ornament, or small area of thick glass at the bottom, will allow dead insects or dirt to collect at that point without marring the appearance of the unit.

(3) Dilute ammonia is an excellent glass-cleanser.

(4) Fixtures should be arranged to be lowered, for cleaning, from above if on a very high ceiling in a church or similar structure.

(5) It should be possible to easily raise the lamp or lamps from within the bowl, to allow of dusting or wiping out.

Figures suggestive of good practice in the selection of mounting-heights and types of light-distribution are given in Table VI.

Table IV. Direct System

LAMP-SIZE, MOUNTING-HEIGHT AND SPACING*

Mounting-height	Commercial size of lamps in watts = W and cubic feet per hour		Watts per square foot = w and cubic feet per square foot		Ideal spacing = distance $\sqrt{\frac{W}{w}}$		Minimum spacing-distance		Maximum spacing-distance

* To determine the size of equivalent Welsbach lamps allow 1 cu ft per hour for each 25 watts. Adapted from the Electric Journal, by A. J. Airston.

The Designing of General Illumination by Each System Using Tungsten or Welsbach Lamps

(1) From Table III should be determined the watts per square foot desirable for the given class of work, and the total number of watts necessary should then be computed.

(2) From Table IV should be obtained the size of unit desirable for a given height of room and the number and spacing of fixtures then computed.

(3) The ceiling should be laid off in squares the sides of which are as nearly as possible equal to the value of the ideal spacing. One fixture should be located at the center of each square.

(4) Each lamp should be checked up on the plan to see that it is useful and clear of obstacles, and the layout incorporated into the building plans using the standard methods and symbols for electricity or gas as the case may be.

Table V. Standard Symbols for Gas-Piping Plans*

 4	Ceiling-outlet; gas only. Numeral indicates the number of single-mantle gas-lamps.
	Single-lamp outlet (ceiling-units, pendants, etc.); gas only.
 $\frac{4}{2}$	Ceiling-outlet; combination. $\frac{4}{2}$ indicates 4 electric lamps and 2 single-mantle gas-lamps.
 2	Bracket-outlet; gas only. Numeral indicates the number of gas-lamps.
 $\frac{4}{2}$	Bracket-outlet; combination. $\frac{4}{2}$ indicates 4 electric lamps and 2 gas-lamps.
 2	Baseboard-outlet; gas only. Numeral indicates number of gas-lamps.
	Floor-outlet; gas only.
	Special outlet (for portable lamp, heater, etc.); gas only.
 $\frac{2}{5}$	Outlet for outdoor-standard or pedestal; gas only. $\frac{2}{5}$ indicates 2 gas-lamps, with 5 mantles per lamp.
 $\frac{6}{2/5}$	Outlet for outdoor standard or pedestal; combination. $\frac{6}{2/5}$ indicates 6 electric lamps, and 2 gas-lamps, with 5 mantles per lamp.
 4	Arc-lamp outlet; gas only. Numeral indicates the number of mantles.
 2	Pump or pneumatic lighting-system. Numeral indicates the number of lamps to be operated from one pump.
2 	Push-button for magnet-valve. The numeral indicates the number of lamps to be operated from one push-button switch.
	Meter-outlet.

Examples of Design of Lighting-System for accounting-office, 63 by 25 ft with 13-ft ceiling (Fig. 1). Walls and ceiling-light in color.

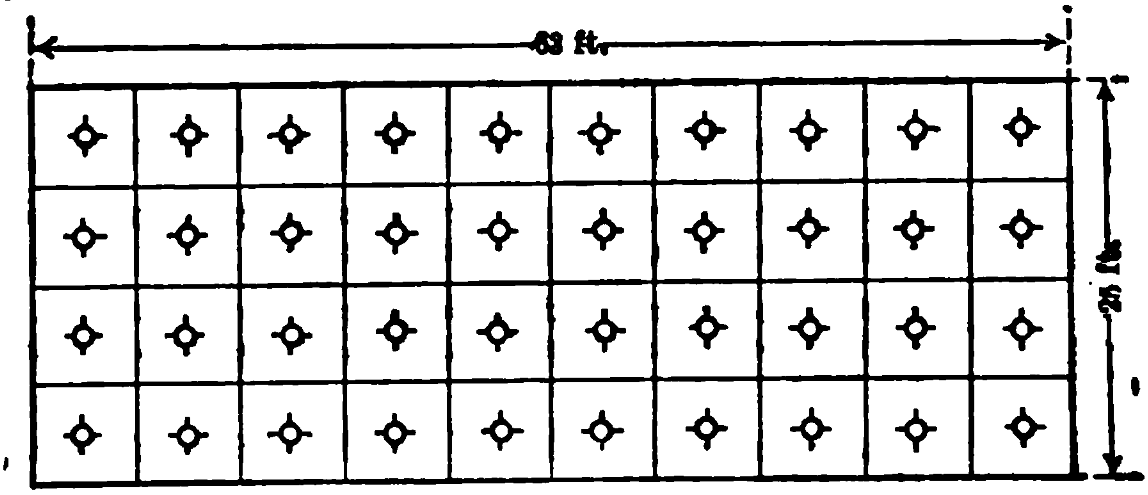

Fig. 1. Plan of Ceiling-lights

Direct System

Watts per sq ft	= 1.5 (Table III)
Total watts	= 1.5 × 63 × 25 = 2 400 (nearly)
Unit, size of	= 60 watt electric (Table IV)
	= 3 cu ft per hour, ordinary inclosed gas, or } about
	= 2 cu ft per hour, Welsbach KINETIC } about
Number of units	= 2 400/60 = forty
Spacing (average) desired	= 6 ft 4 in (Table IV)
Number of rows	= 25/6⅓ = four
Number of outlets per row	= 40/4 = ten
Spacing between rows	= 25/4 = 6¼ ft
Spacing in rows	= 63/10 = 6⅓ ft
Spacing-average	= 6 ft 4 in.

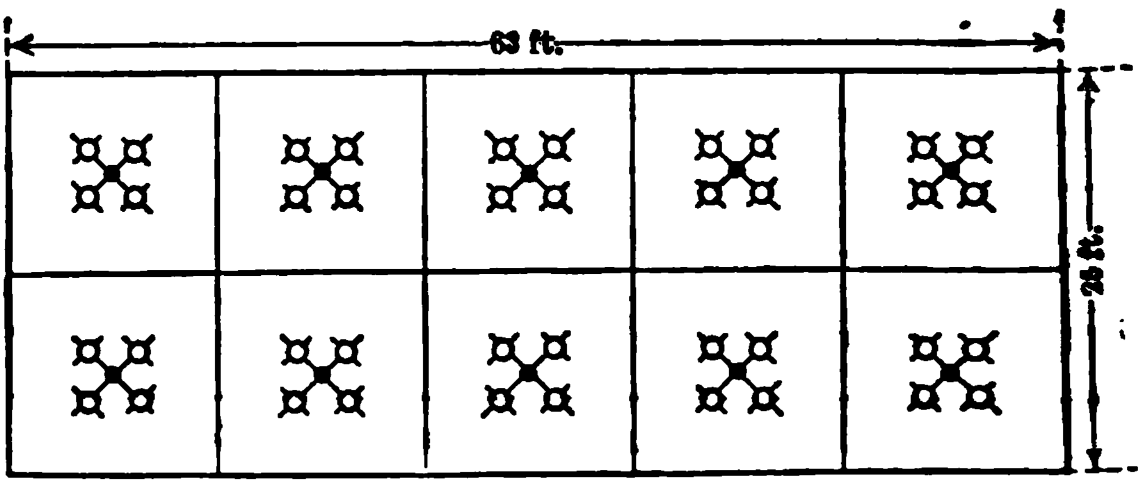

Fig. 1A. Modification of Plan Shown in Fig. 1

Fig. 1A is a modification of the plan shown in Fig. 1, and is a great improvement. It will not produce such even illumination but will result in a much

rtistic effect, especially if fixtures are chosen which harmonize with the furnishings of the room. The lamps are placed in groups of four on ten fixtures and these are equally spaced throughout the room. Here again it is always possible to use lamps of higher wattage at any point where the illumination is not sufficient. The importance of a proper choice of reflector is shown from a study of Figs. 2 to 5.* It will be noted in Fig. 2 how a bare tungsten-lamp throws the greater part of its light to the walls. The distribution of any light can be controlled to a remarkable extent by the use

Fig. 6. Example of Type of Fixture Used in Semiindirect System. Macbeth-Evans Company

Indirect or Semiindirect Systems, for Electricity

Watts per sq ft	= 1.5 (Table III)
Total watts	= 2 400, nearly
Average spacing	= 14 to 24 ft (Table VI)*
Select 25/2	= 14 ft for lamps in two rows
Number of units in row	= 63/12.5 = five
Spacing in row	= 63/5 = 12 ft 7 in, about
Type of reflector	= Concentrating (Table VI)
Distance from reflector to ceiling	= 30 in (Table VI)
Number of units	= two rows of five each = ten
Watts per unit	= 2 400/10 = 240
Lamps per unit	= one, 250 watts four, 60 watts six, 40 watts

Calculations for this Example for Gas-Lighting

Welsbach kinetic burner used.

Cu ft per hour per sq ft	= 0.06 × 0.6 = 0.036 (Table III)
Total hourly consumption	= 63 × 25 × 0.036 = 57 cu ft per hour.
Average spacing (see above)	= 12½ ft
Number of units	= ten

Consumption per unit = 57/10 = 6

Reflector and mounting-height as in preceding problem

Lamps per unit = one, 6 cu ft

Lamps per unit = two, 3 cu ft, etc.

* See How to Use Table VI, immediately following the Table.

One side of the limiting square in feet that can be uniformly illuminated from one center outlet

Table VI gives the distance in inches (except as noted) from the top of the refle the ceiling to obtain the desired distribution of light from one ceiling-outlet.

Where values are not given to the left, it is advisable to submit data to illumi engineers and for greater ceiling-heights than 20 ft.

* H. B. Wheeler, X-Ray Eye-Comfort Company.

An idea of the appearance of some of the typical modern fixtures using gas or electricity in these systems of lighting may be obtained from Figs. 6, 7 and 8.

Fig. 7. Type of Fixture in Indirect Illumination. National X-Ray Reflector Company

Fig. 8. Fixture Used for Gas by Either Indirect or Semiindirect System

How to Use Table VI. In the first column of Table VI is located the height of ceiling, in this case, 13 ft. The last square to the right of this figure, which has a number in it, is noted. In this case the last square to the right of 13 ft, which has a number in it, contains the number 48. By following this column containing the number 48 down to the figures printed in heavy type at the bottom of the table, the heavy-faced number in this case is found to be 24. This 24 is the length of the side of the largest square which a single fixture can properly illuminate when the ceiling is 13 ft high. The 48 which is opposite the 13 is merely the number of inches the fixture must be hung from the ceiling. Thus the largest squares into which we can possibly divide the ceiling have 24-ft sides. But a room 25 ft wide cannot be divided into 24-ft squares. We are compelled, therefore, to divide it into squares of a smaller size, since the fixtures will not illuminate any larger square. The greatest length into which we can divide 25 ft is 12½ ft. We may, then, decide to use fixtures which will illuminate 14-ft squares. Locate the number 14 in heavy type at bottom of table, and trace up the column in which it is found until the square is reached which is opposite the ceiling-height of 13 ft. Here the number 30 is found. This means we must hang the fixture so that the top of it is 30 in from the ceiling in order to get the desired results. Looking along the squares to the right of the one in which we find the 30, we find the word CONCENTRATING which signifies the type of reflector advised for this installation.

School-Room Lighting.* The following illumination-constants have been worked out by experiments and experience covering a wide range of conditions. In each of the following cases light tinted walls and ceilings are taken as a standard.

Auditoriums and Lecture-Halls. Since no continuous reading is required here, 0.75 watt per sq ft, direct system, is all that is needed, if it is properly diffused to a pleasant softness.

Class-Rooms and Laboratories. These must be lighted for the purpose of writing notes and taking accurate readings of instruments. Thus 1¼ watts per sq ft, direct system, are required.

Wood-Working Shops. The surfaces here are generally high and offer good reflecting properties, so that 1½ watts per sq ft, direct system, are sufficient.

Machine-Shops. Because the belts, machines and dingy floors offer great absorbing surfaces at least 2 watts per sq ft, direct system, are necessary.

Foundries. The dark molding-sand and the dust and smoke in the air make 3 watts per sq ft, direct system, necessary.

Drafting-Rooms. The semiindirect system with 2¼ watts per sq ft (about the equivalent of 1¾ watts per sq ft, direct system) has proved highly satisfactory.

Illumination by Gas.† Recent progress in incandescent gas-lighting has resulted in the development of appliances in which practically all of the shortcomings of previous types are overcome, and except for inaccessible locations, or where lamps are very infrequently lighted, there is little to choose between the two illuminants, gas and electricity, upon the score of convenience or of artistic possibilities, while the greater economy of gas-lighting (often in the ratio of about 2½ to 1) coupled with the freedom from interruption which characterizes gas-service makes it desirable to pipe all buildings, particularly residences, for gas throughout, preferably installing combination-fixtures and providing wall-outlets and baseboard-outlets for the connection of the various gas-operated conveniences which are being developed in rapidly increasing numbers.

Welsbach Kinetic-Burner Lamps With Nearest Equivalent Sizes in Electric Incandescent Lamps

8 mantles 20.0 cu ft per hour	....	500
10 mantles 25.0 cu ft per hour	....	750

Gas-Lamps are available in a variety of types and sizes. The most recent development is the KINETIC burner of the Welsbach Company in which the efficiency is increased by from 50% to 100% over the previous types. With this burner no enclosing glassware or housings are required, and the lamp is said

* A. L. Williston. † R. F. Pierce, Welsbach Company.

to require no attention beyond the renewal of mantles every 2 000 burning-hours. There is practically no depreciation in candle-power during this interval. Ignition is accomplished either by a pilot-flame burning about 1/10 cu ft per hour, or by electrical means, and several types of distant control are available. The following table gives the sizes in which these lamps may be obtained and the nearest equivalent sizes in electric incandescent lamps.

Selection of Illuminants

(1) Factors favorable to the use of electricity:
- Units less than 60 candle-power required.
- Lamps in inaccessible positions.
- Lamps lighted at infrequent intervals.
- Lamps placed very close to ceiling (12 in or less).
- Poor gas service as regards:
  - Pressure-regulation (more than 50% variation from minimum).
  - Non-uniformity of gas-quality.
  - Imperfect purification.
- Good electric service as regards:
  - Voltage-regulation.
  - Freedom from liability to derangement by accident.
- Non-rigid fixtures.

(2) Factors favorable to the use of gas:
- Units of 60 candle-power or more.
- Accessible locations.
- Frequent use of lamps.
- Lamps placed 15 in or more from ceiling.
- Good gas service as regards:
  - Pressure-regulation (not more than 50% variation from minimum).
  - Uniformity of gas-quality (chemical composition).
  - Proper purification.
- Poor electric service as regards:
  - Voltage-regulation (more than 5% variation from maximum) most likely on alternating-current circuits.
  - Liability to derangement by accident (overhead circuits).
  - Rigid fixtures.

Hygiene.* From the hygienic point of view there is little to choose between the two illuminants. The investigations of Dr. Rideal have shown that: (1) Gas-light positively improves the air for breathing purposes under the actual conditions of use. The causes of this improvement are the acceleration of ventilation, the destruction of disease-germs and the addition of necessary moisture. Gas-burners give rise to stronger air-currents and invariably produce a more active ventilation and diffusion of air than electric lights; hence, along with the products of the gas-burner, the exhalations of persons present are more rapidly removed; (2) The ascending currents of air from the gas-lights on reaching the ceilings rapidly part with their heat, which is conducted away by the rafters and joists; (3) The electric lamps produce more heat than is commonly accredited to them, and this is the explanation of the unexpected result that the average temperature of the room is practically the same under either illuminant, and that the electric light does not show the superiority in coolness usually claimed. When excessive temperatures are encountered in gas-lighted

* See Relative Hygienic Values of Gas and Electric Lighting, by Samuel Rideal, Transactions Royal Sanitary Institute, March, 1908.

rooms, it will be found due to the radiant heat from low-hung lamps of excessive size. On account of the economy of gas-lighting, it is a common practice to provide from four to six times as much illumination as is required. Dr. Rideal's tests also emphasized, what is a matter of common experience, that under direct lighting, the lower brilliancy of the gas-mantle reduced the glare from glazed papers to such an extent as to be noticeable in the results: "The sensitiveness of the eye to light as measured in the perception-test diminished very markedly after exposure to the electric light, while no corresponding effect is noticeable after the eye has been subjected to gaslight. All the results point strongly in the same direction, namely, that gaslight, as used in these experiments, is less fatiguing to the eye than electric light." Under semi-indirect or indirect lighting, of course, no such disparity in effect is found.

The Foregoing Rules Indicate the General Practice in planning the illumination of a room. It must be said, however, that this set of rules must not be followed too slavishly. In illumination no rules can take the place of judgment and intelligence. Each project must be considered more or less as a problem by itself, for which previous experience and former installations should be made to furnish data and to suggest methods. It is well, therefore, when planning the illumination of a room, to visit as many similar rooms as possible, note the effect of the systems in use and obtain data as to their efficiency, cost, etc. The most successful scheme may then be used as the basis for planning the desired installation.

The Diffusion of Light through Windows *

Tests on the Diffusion of Light by Glass. Abstracts from report of Charles L. Norton, on an elaborate series of tests made at the Massachusetts Institute of Technology:† The results of the tests on a score or more of different glasses may be stated briefly. We may increase the light in a room 30 ft or more deep to from three to fifteen times its present effect by using FACTORY-RIBBED GLASS instead of PLANE GLASS in the upper sashes. By using prisms we may, under certain conditions, increase the effective light to fifty times its present strength. The gain in effective light on substituting ribbed glass or prisms for plane glass is much greater when the sky-angle is small, as in the case of windows opening upon light-shafts or narrow alleys. The increase in the strength of the light directly opposite a window in which ribbed glass or prisms have been substituted for plane glass is at times such as to light a desk or table 50 ft from the window better than one 20 ft from the window had previously been lighted.

The Kinds of Glass Tested were as follows:

(1) Ground glass of different degrees of fineness.

(2) Rough plate or hammered glass.

(3) Ribbed or corrugated glass, with five, and eleven and twenty-one ribs to the inch, the corrugations being sinusoidal in outline, as in *A*, Fig. 9, and the back of the plate smooth.

(4) Glass known as MAZE, FLORENTINE or FIGURED, in which a raised pattern is worked upon one side, practically roughening the whole surface.

(5) Wash-board glass, corrugated, with twenty-one ribs to the inch on one side and five ribs to the inch on the other side, the ribs being parallel.

(6) Skylight-glass, which has five ribs to the inch on each side, the groove on one side being opposite the rib on the other, giving a sinuous section *B*, Fig. 9.

* See, also, the subjects Pressed Prism-Plate Glass and Prism Glass, Part III, pages 1577 to 1579.

† From Report No. III, Insurance Engineering Experiment Station, September, 1902.

(7) Ripple-glass, with rippled surfaces on both sides; of very beautiful appearance and a clear white color.

(8) Glass ribbed on one side and figured on the other.

(9) Ribbed glass with a wire net pressed into it, to increase its resistance to fire.

Of these several specimens, one or two may be dismissed with brief mention. Ground glass is of little value, except as a softening medium for bright sunlight. Its rapidly increasing opaqueness with moisture and dust makes it undesirable as a window-glass. The common rough plate has very little action as a diffusing-medium, giving no perceptible change in the effective light. Ripple-glass has great value as a diffusing-medium in small rooms with nearly open horizon. Of the ribbed glasses, the fine Factory-Ribbed, with twenty-one ribs to the inch, is distinctly the best, not in all probability because of the fineness, but because of the greater sharpness of the corrugations.

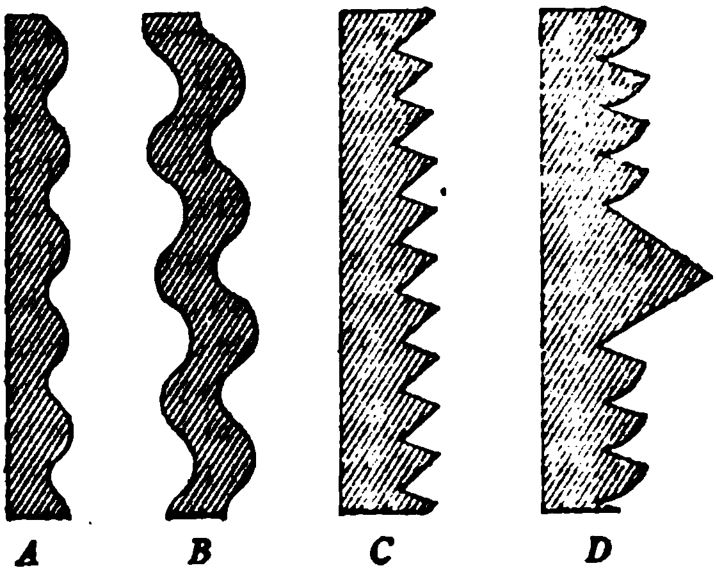

Fig. 9. Types of Ribbed or Prism-glass

The Ribbed wire-glass is about 20% less effective than the ordinary Factory-Ribbed glass. The addition of a second corrugation upon the back of the plate giving the Skylight and Wash-Board glass is of no apparent value. The raised pattern imprinted upon one surface of the glass, as in the case of the Maze glass, gives the widest diffusion, especially in bright sunlight. A raised figure, when worked upon the back of the Ribbed glass, renders it less offensive to the eye in bright sunlight, but less effective in deep rooms. The only glasses of this group which it is worth while, then, to discuss further are the Factory-Ribbed and the Maze glass.

The second group comprises the following glasses:

(1) The Luxfer prisms.

(2) The Solar prisms.

(3) The Daylight-prisms.

(4) The glass of prismatic section made by the Mississippi Glass Company.

(5) Three-way prisms.

(6) Maltby prisms.

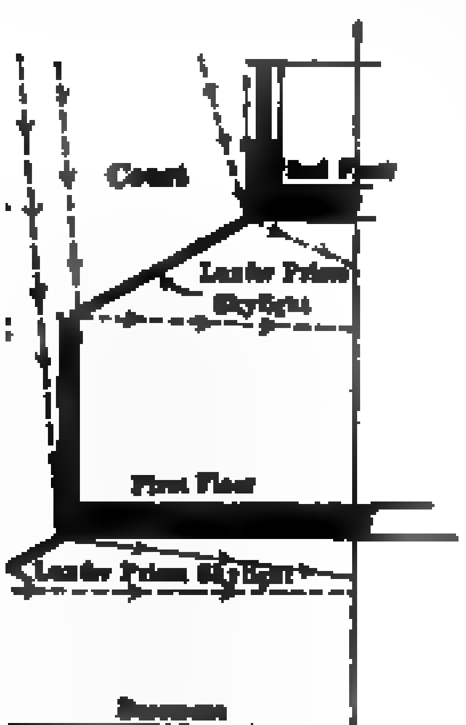
The Luxfer prism consists of a plate smooth on one side and deeply notched on the other as in *C*, Fig. 9, the teeth or prisms being of very flat, smooth faces of brilliant appearance. The glass is clear white, and the prisms used in canopies and in the major part of the vertical glazing are made in tiles or plates about 4 in square. Tiles are built up in large sheets in frames of copper or brass, so made as to give to the sheets of tiles a strength and durability far in excess of a single sheet of the same size. The Luxfer prisms are made for factory-use in large sheets, as well as in the small tiles. The Solar prisms are made in small tiles, which are held together in a metal frame to make large sheets. The main difference between the Solar and Luxfer prisms is that the under face of the former prism is curved instead of plane, as in *D*, Fig. 9. The Daylight-prisms tested were made in large sheets and of approximately the same cross-section and general appearance as the Luxfer prisms for factory-use. No tiles of Daylight-prisms were tested, as none came to hand in time for the test. The Mississippi prism glass is much like the other prisms in cross-section, but the ridges or

ns do not run across the plate in a straight line, but in a wavy or sinuous line. advantage arising from this over the straight-edge prism was detected.

onclusions. (1) The conditions in a room less than 15 ft deep are such , except with a skylight of less than 45°, it is not advisable to alter the general se of the light by using a prismatic or ribbed glass. A nearly hemispherical sion, such as is given by the e or Ripple-glass, is ordiy preferable.

) When a room is from 20 ft deep, or even more, and a skylight of 60° or less, the d and prismatic glass results very great gain in effective . The gain in brilliancy is as to make a basement with canopies as light as a d story with plane glass. oms with windows opening light-shafts and narrow s with very limited openings e sky, where the available is now small, may have the light 20 ft back from the window increased ten enty times by using prisms; and, by using canopies of prisms, it is somepossible to strengthen the light fifty to one hundred times. With skys of 30°, or less, and in deep rooms, the relative efficiency of the prism creases greatly. The refraction of the incident ray in a case of the ribbed glass and prism is shown in Fig. 10. Ribbed and maze glass are of very great value in softening the light, especially in the case of such windows as are exposed to the direct sun, aside from their effectiveness in strengthening the light at distant points. With the Maze glass, the artist may have, in all weather and in all directions, what is in effect a much-desired NORTH LIGHT. The photographer may have in this way as well diffused a light as he now has with cloth screens or shades, and with a much greater intensity. To be efficient in rooms 20 ft deep or more, ribbed glass should be set with its ribs horizontal, and where the sunlight falls upon it, it should be provided with thin white shades. All inferences drawn from the test are made upon the assumption that the windows are to be glazed with diffusing glass only in the upper half, which is the common practice. If the lower sash is to be glazed diffusing glass as well, a further increase of about 25% may be ed.

Fig. 10. Refraction of Light in Ribbed and Prism-glass



1. Basement and First Story Lighted from Court

nsidering both expense and efficiency, the following general suggestions are Use Maze or Ripple-glass in small rooms or offices not more than 15 or 20 ft use Factory-Ribbed glass in rooms from 30 to 50 ft deep, with sky-angles of more; use prisms or Factory-Ribbed glass, in sheets, in all vertical win-

dows in rooms more than from 50 to 60 ft deep, with sky-angle of less than 45°. With a sky-angle of less than 30° use prisms in canopies. Fig. 11 shows an effective method of lighting the basement and first story where the light must come from a court.

ELECTRIC WORK FOR BUILDINGS

By
W. H. TIMBIE
ASSOCIATE PROFESSOR OF ELECTRICAL ENGINEERING, MASSACHUSETTS INSTITUTE OF TECHNOLOGY

General Considerations and Definitions. Electrical energy is now in common use, furnishing power, heat and light, operating bells and buzzers, and transmitting messages by telephone and telegraph. In order to accomplish these results, a current of electricity must flow around an electric circuit. The nature of electricity is not known, but the flow of it through an electric circuit is analogous to the flow of water through a system of pipes.

Current. Amperes. The flow of water is measured in GALLONS PER SECOND. The flow of electricity is measured in AMPERES. An ampere-flow of electricity is analogous to a gallon-per-second flow of water. The amperes thus indicate the quantity of electricity flowing through an electrical appliance in one second. About ½ ampere is flowing through an ordinary carbon-filament incandescent lamp when it is glowing at 16 candle-power. The same current of ½ ampere causes a modern tungsten lamp to produce over 40 candle-power. An arc-lamp usually requires a flow of from 5 to 10 amperes.

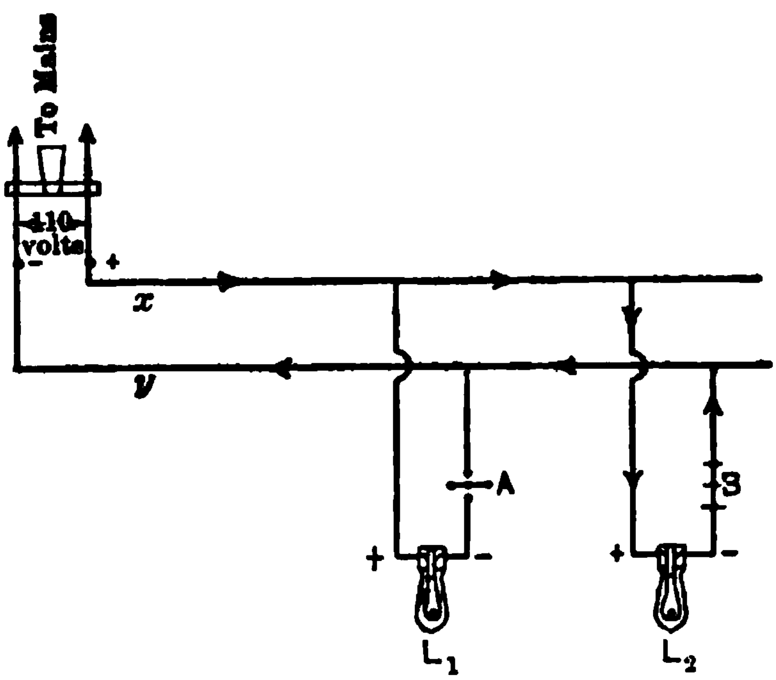

Fig. 1. Current Always Flows from (+) to (−)

Pressure. Volts. When a current of water flows from one point to another in a pipe-system, it is always because there is a hydraulic pressure present causing it to flow. This pressure is usually measured in pounds per square inch. Similarly, when a current of electricity flows from one point to another in an electric circuit, it is because there is an electric pressure present which causes it to flow. This electric pressure is measured in VOLTS. An electric pressure of 1 VOLT is analogous to a hydraulic pressure of 1 lb per sq in. The pressure which causes the ½-ampere current to flow through an incandescent lamp is usually 110 volts. The electric company instals at least two wires in a residence and then maintains an electric pressure of 110 volts between them just as the water company maintains a pressure in the water-pipes. This electric pressure is at all times tending to force electricity from one wire to the other wire across the space between the two wires, just as the water-pressure tends to force the water out from the pipe. The rubber insulation is put on to prevent this flow, very much as the strength and compactness of the iron prevents the flow of water through the walls of the pipe. But when one terminal of a lamp is connected to one wire and the other terminal to the other wire, the electric pressure tending to send a current from one wire to the other, sends a current through the lamp and causes it to glow. We mark the wire bringing the

current to the lamp (+). The wire taking the current away, we mark (−). Thus in Fig. 1, if the current comes in on the wire marked (x), this wire is (+) and the wire (y) is (−). A pressure of 110 volts is maintained which tends to cause a current to flow across from the wire (x) to the wire (y). No current can flow, however, unless some path is afforded between the two wires. For instance, no current is flowing through lamp L_1, because the open switch A makes a gap across which the current cannot pass. Switch B, however, is closed, thus allowing the pressure to force a current from the wire (x) through the lamp L_2 to the wire (y) and back into the street-mains. Of course the electric company maintains the 110-volt pressure between the wires (x) and (y) whether any current is drawn from the wires or not, just as a water company maintains the pressure in the water-mains whether any water is drawn from the pipes or not.

Resistance. Ohms. The fact that a current of only ½ ampere flows through an incandescent lamp when a pressure of 110 volts is applied to it, is due to the RESISTANCE of the fine filament. This resistance of the filament is analogous to the resistance which a pipe of small bore offers to the flow of water. The resistance of an electrical appliance is merely the ratio of the pressure to the current which that pressure can force through it. As an equation, it is expressed

$$\text{Resistance} = \frac{\text{pressure}}{\text{current}}$$

When the pressure is measured in volts and the current in amperes, the resistance is then in ohms. Thus

$$\text{Ohms} = \frac{\text{volts}}{\text{amperes}}$$

Thus, since a pressure of 110 volts forces ½ ampere through an ordinary incandescent lamp, the resistance of the lamp is 110/½ = 220 ohms.

Ohm's Law. This relation between pressure, current and resistance is called OHM'S LAW. It is written in symbols in the three forms

$$R = E/I$$
$$E = IR$$
$$I = E/R$$

where

R = resistance in ohms;
E = pressure in volts;
I = current in amperes.

Example. An electric flat-iron has a resistance of 35 ohms. What current will flow through it when it is put across a 110-volt circuit?

$$I = E/R = 110/35 = 3.14 \text{ amperes}$$

Example. An electric toaster takes 1½ amperes when on a 115-volt circuit. What resistance does it have?

$$R = E/I = 115/1.5 = 76.6 \text{ ohms}$$

Insulators and Conductors. In order that practically no current may leak from one wire to the other, the wires are covered with rubber. This rubber covering offers such high resistance to the flow of an electric current that, although two wires may lie very close to one another with only this rubber between them, practically no current leaks through the rubber from one wire to the other. Materials such as rubber, glass, porcelain, dry wood, etc., have this resisting property and are said to be INSULATORS. Metals, on the other hand, offer very little resistance to the flow of an electric current and are called con-

DUCTORS. A copper wire $\frac{1}{10}$ in in diameter has a resistance of only $\frac{1}{1000}$ of an ohm per foot. Accordingly, because of their low resistance, copper wires are generally used to carry electric currents, and because of its high resistance, rubber is generally used as a covering of the copper wires to prevent leakage from one wire to another. Wire, approved by the National Board of Fire Underwriters and installed according to their rules, will have the proper insulating covering for each installation.

Power. Watts. The flow of an electric current has been likened to the flow of water through a pipe. A current of water is measured by the number of gallons, or pounds, flowing per minute; a current of electricity is measured by the number of amperes. The power required to keep a current of water flowing is the product of the current in POUNDS PER MINUTE by the head, or pressure, in FEET. This gives the power in FOOT-POUNDS PER MINUTE. To reduce to horse-power, it is necessary merely to divide by 33 000. Thus

$$\frac{\text{(pounds per minute)} \times \text{(feet)}}{33\,000} = \text{horse-power}$$

In exactly the same way, the POWER required to keep a current of electricity flowing is the product of the current in AMPERES by the pressure in VOLTS. This gives the power in WATTS.

$$\text{Watts} = \text{amperes} \times \text{volts}$$

The term WATT is merely a unit of power, and denotes the power used when one volt causes one ampere of current to flow. The watts consumed when any given current flows under any pressure can always be found by multiplying the current in amperes by the pressure in volts. Thus, if an incandescent lamp takes 0.5 ampere when burning on a 110-volt line, the power consumed equals

$$0.5 \times 110 = 55 \text{ watts}$$

That is,

$$\text{Power} = \text{current} \times \text{pressure}$$

or

$$\text{Watts} = \text{amperes} \times \text{volts}$$

Example. What power is consumed by a motor which runs on a 220-volt circuit, if it takes 4 amperes?

$$\text{Watts} = \text{amperes} \times \text{volts} = 4 \times 220$$
$$\textbf{Power} = \textbf{880 watts}$$

Incandescent lamps are rated as to the voltage of the line on which they can run, and also as to the amount of electric power it takes to keep them glowing. Thus, a carbon-filament lamp may be rated as a 110-volt, 50-watt lamp. A tungsten-lamp may be rated as a 110-volt, 25-watt lamp. This means that both lamps are intended to run on a 110-volt circuit, but that it takes twice as much power to keep the carbon-filament lamp glowing as it does to keep the tungsten-lamp glowing.

The Power-Equation. The above relation between volts, amperes and watts is usually expressed in the form of an equation:

$$P = IE$$
$$I = P/E$$
$$E = P/I$$

where

P = power in watts;
I = current in amperes;
E = pressure in volts.

Example. What current does a 40-watt tungsten-lamp take when running on a 115-volt circuit?

$$I = P/E = 40/115 = 0.348 \text{ ampere}$$

Power. Kilowatt and Horse-Power. Because the watt is so small a unit of power, being only 0.74 ft-lb per second, a larger unit, the kilowatt, is generally used in connection with machines, etc.

$$1 \text{ kilowatt} = 1\,000 \text{ watts} = 1\tfrac{1}{3} \text{ horse-power}$$

Thus a motor drawing 10 amperes from a 220-volt line would take $10 \times 220 = 2\,200$ watts $= 2\,200/1\,000 = 2.2$ kilowatts.

At 80% efficiency this motor would give out 80% of $2.2 = 1.76$ kilowatts $= 1.76 \times 1\tfrac{1}{3} = 2\tfrac{1}{3}$ horse-power.

Horse-Power-Hour. Kilowatt-Hour. When a man buys mechanical power to run machinery, he has to pay not only according to the horse-power he uses but also according to the number of hours he uses the power. For instance, he may use 40 horse-power for 1 hour and pay $1.20 for it, that is, at the rate of 3 cts for each horse-power-hour. If he uses 40 horse-power for 2 hours he would have to pay twice as much, because he has used the same power twice as long. Another way of stating the same fact is to say that he used twice as many horse-power-hours. For in the first instance he used 40×1, or 40 horse-power-hours, and in the second 40×2, or 80 horse-power-hours. In other words, he did twice as much work in the second case as he did in the first, or received twice as much energy. The unit of work or energy, then, is the HORSE-POWER-HOUR, and is the work done in 1 hour by a 1-horse-power machine.

Example. How much work is done by a machine delivering 15 h.p. when it is run for 8 hours?

1 h.p. in 1 hr does 1 h.p.-hr
15 h.p. in 1 hr does 15 h.p.-hr
15 h.p. in 8 hr does 8×15, or 120 h.p.-hr

That is

$$\text{Work} = \text{horse-power} \times \text{hours}$$

or

$$15 \times 8 = 120 \text{ h.p.-hr}$$

Similarly, electric power is sold by the KILOWATT-HOUR. This unit is the work or energy delivered in one hour by a 1-kilowatt machine.

For lighting purposes electrical energy is usually sold for from 10 to 15 cts per kilowatt-hour. Thus at 12 cts per kw-hr the monthly bill for burning a 40-watt lamp on an average of 5 hours per day would be computed as follows:

For 1 month of 30 days the lamp is burning

$$30 \times 5 = 150 \text{ hours}$$

To use a 40-watt lamp 150 hours consumes

$$40 \times 150 = 6\,000 \text{ watt-hours} = 6\,000/1\,000 = 6 \text{ kilowatt-hours}$$

At 12 cts per kw-hr, 6 kw-hr cost

$$6 \times 12 = \$0.72$$

An instrument called a KILOWATT-HOUR METER is placed in each house to measure the number of kilowatt-hours which each customer consumes. See *M* in Fig. 13 for location of Kilowatt-hour meter, and Fig. 18 for method of connection in typical installation.

Heating-Effect of Current. An electric current always heats the material through which it passes. Examples of this are the incandescent lamp, in which

ie current heats the fine tungsten wire until it glows; the electric heaters for ıafing-dishes, toasters, etc. Even the wires carrying the current to and from ıe lamps are heated by the passage of the current through them. But since the ıating effect for a given current is directly proportional to the resistance of ıe conductor, and the conductors always have very little resistance, the heat-g here is very slight indeed. If conductors of smaller size, and therefore of higher resistance, were used, the heating would be very pronounced; in fact, would soften the rubber insulation and might even produce a temperature high ough to set fire to the building. For this reason The National Board of re Underwriters issues a table specifying the size of wire which must be used r each amount of current. If smaller wire is used, the resistance of it might great enough to raise the temperature to a dangerous degree. On the other nd, if a greater current than allowed by this table is sent over the wire, the nperature will also rise, because the heating of a current is also directly pro-rtional to the SQUARE OF THE CURRENT. Thus, doubling the current which a tain wire is carrying will quadruple the amount of heat which the wire must liate. For this Tables III and IV, see pages 1473 and 1474.

Fuses and Circuit-Breakers. Use is made of the heating effect of a current protect a circuit against too much current, very much as a boiler is pro-ted by a safety-valve against too much pressure. A small piece of fusible tal, generally a mixture of lead and bismuth, is inserted in the circuit in such ay that all the current which passes through the circuit must also pass through

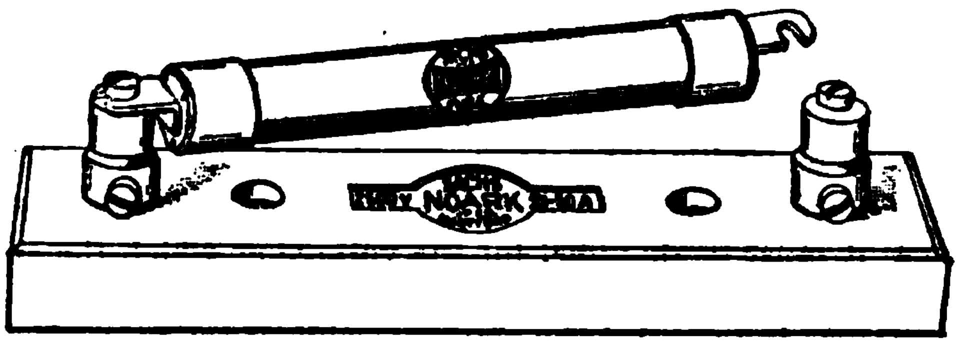

Fig. 2. Enclosed Fuse

piece of metal. This device is called a FUSE. Any current which would be gerous to the circuit melts this fuse, opens the circuit at this point, and thus ects the rest of the circuit from the effects of the current. The cause of large current may be then removed and a new fuse inserted in place of the one. CIRCUIT-BREAKERS are also used to protect a circuit against too much ent. They are AUTOMATIC SWITCHES controlled by an electro-magnet and made in a variety of styles. They operate upon the principle that when electric current passes through a coil of wire it makes a magnet of the coil. coil is so adjusted that when a current of a certain number of amperes es through it, it attracts to itself a small piece of iron. The motion of this e of iron opens the circuit. Fuses and circuit-breakers are thus AUTOMATIC TY-DEVICES required for the protection of all constant-potential systems tever the voltage. Both are for the purpose of protecting the wires from age due to the presence of too much current from any cause whatever. ordinary fuse consists of a porcelain base that has suitable terminals for ting a fuse between the ends of a wire. It must be constructed so that the ing out of a fuse can do no damage, that is, set anything on fire, and placed e it can easily be reached to replace the fuse. Formerly a piece of fuse-wire, d a LINK-FUSE, was used in cut-outs, but the underwriters now require en-d fuses (Fig. 2) or fusible plugs which screw into a receptacle. Fuse-

plugs may be used for currents up to 30 amperes; above that enclosed fuses must be used. Fuse-plugs and enclosed fuses are somewhat more expensive than the link-fuse, but are considered safer. A FUSE CUT-OUT or CIRCUIT-BREAKER is required at or near the place where the wires enter a building, and every circuit of twelve 16-c.p. carbon-lights or of sixteen 40-watt tungsten-lights must be protected by a cut-out. Circuit-breakers are more expensive than fusible cut-outs, and are generally used only on SWITCHBOARDS for large installations and where it is desirable to open the circuit instantly on certain loads, which a fuse cannot be depended on to do with any degree of accuracy, owing to both time and surrounding temperature-factors. Circuit-breakers are also used largely on installations where the variation in load is large and frequent and the repeated burning out of fuse would become expensive not only for renewals but also on account of the time required to replace them.

Lamps. Two kinds of lamps are used for electric lighting, INCANDESCENT LAMPS and ARC-LAMPS. The former are used principally for interior illumination, although sometimes used for street-lighting, especially where the streets are thickly shaded by trees. Arc-lamps are especially adapted for street-lighting and for large interiors where they can be kept concealed or above the range of the eye, as in railway-stations, stores, etc. An incandescent lamp as commonly made consists of a glass bulb containing a simple carbon or a tungsten conductor the ends of which are connected to the source of the electric current. When the current flows through the filament it heats it to such a degree that it becomes incandescent; hence the name of the lamp. The lamps with the filament of finely-drawn tungsten represent the latest type and are superior in every way to those having a carbon filament. Tungsten-lamps require about one-third as much power to produce the same candle-power as carbon-lamps, and have a much longer life.

Voltages. In order that the current shall cause the lamp to give its rated CANDLE-POWER, it must be designed for the voltage at which the system is run. If the voltage of the current is much greater than that for which the lamp is designed it will quickly burn out the filament, while if the voltage of the current is below that of the lamp, it will not give its rated candle-power, a voltage 10% lower reducing the candle-power about one-half. The voltage commonly used for tungsten-lamps is from 100 to 130. Tungsten-lamps are also made for voltages of from 20 to 260. Two to four candle-power lamps, for illuminating signs or decorative purposes, are made for from 10 to 13 volts by ½-volt steps, these lamps being commonly used in series, ten lamps on a 100 to 130-volt circuit. Two 5-watt lamps, 50 volts, are also often used in series on a 100-volt circuit.

Candle-Power. Incandescent lamps of from 100 to 130 volts are commonly made 15, 20, 25, 40, 60, 100, 150, 250, 400 and 500 watts. These lamps average 1 candle-power for every 1.1 watts. For the method of computing the number, size and distribution of tungsten-lamps for illuminating a given room see pages 1476 to 1478.

Arc-Lamps. These are of two kinds, OPEN ARC-LAMPS and ENCLOSED ARC-LAMPS, the latter being generally used for interior illumination. The light from the enclosed arc is much softer and steadier than that from the old-style open arc; there are no sparks, and the life of the carbon is from twelve to fifteen times as great as in the open arc.

"**Direct-Current Open Arcs** usually require about 10 amperes at 45 volts, or 450 watts. The range of voltage is from 42 to 52 for ordinary constant-current arcs. The most satisfactory light is given by from 45 to 47 volts.

rc-lights used for stereopticon-lanterns may use as high as 25 amperes and rovision should always be made in the wiring-plans for such a light for suffi-ently large wires to be installed to carry one and one-half times this current.

"**Direct-Current Enclosed Arcs** consume about 5 amperes at 80 volts, or o watts." Arc-lamps generally require a resistance in series with the arc order to regulate properly. This resistance is usually placed within the struc-re of the lamp, and may be so adjusted that a single lamp can be made to ırn well on any circuit from 100 to 130 volts.

Dynamo-Electric Machines. There are three classes of dynamo-electric ıchines:

(1) GENERATORS for generating an electric current.
(2) MOTORS for converting electrical into mechanical energy.
(3) TRANSFORMERS and ROTARY CONVERTERS.
  (*a*) Transformers for converting one voltage into a higher or lower voltage. Converters and transformers belong to the same class.
  (*b*) Rotary converters for changing alternating currents to direct currents or vice versa.

A DYNAMO is either a motor or a generator. A MOTOR is the same machine as ;enerator, but with the nature of its operation reversed. GENERATORS are two general classes, namely, continuous-current and alternating-current .chines; the latter are commonly called ALTERNATORS. Generators and tors of all kinds vary in voltage, current and speed, according to the pur-e for which they are designed. A TRANSFORMER consists essentially of two ls of wire, one coarse and one fine, wound upon an iron core. Its function o convert electrical energy from one voltage to another. If it reduces the tage it is known as a STEP-DOWN transformer, and if it raises it, it is known ı STEP-UP transformer. A transformer has no moving parts and requires no endant.

Kinds of Currents Produced. There are two kinds of electrical currents ımonly used for light and power in buildings, (1) DIRECT CURRENTS, and (2) ERNATING CURRENTS.

A direct current is uniform in strength and direction, while an alternating rent rapidly rises from zero to a maximum, falls to zero, reverses its direction, ıins a maximum in the new direction and again returns to zero. A complete of these changes is called a CYCLE. The number of times the current goes ough these changes during each second is called the FREQUENCY of the current. frequency commonly used for incandescent lighting is 60 cycles per ond; that is, the current goes through the above changes in value 60 times second. A frequency of 25 cycles is also in common use, especially for run-g motors, although it is not so satisfactory for use with incandescent lights. direct current is likened to the steady flow of water through a pipe-system, alternating current may be likened to the rapid surging back and forth of er in a pipe-system. More difficulty was experienced in utilizing these rapid ;es of electricity than in developing direct-current apparatus. Consequently use of the alternating current was retarded but is now becoming general. advantages of alternating over direct currents are: (1) Greater simplicity ynamos and motors, no commutators being required in some types; (2) the ibility of obtaining high voltages by means of transformers for cheapening cost of transmission; (3) the facility of transforming from one voltage to ther, either higher or lower, for different purposes."*

* Adapted from Kent's Pocket Book.

Table I. Average Current Taken by Direct-Current Motors

Horse-power	Amperes on 110-volt line	Amperes on 220-volt line	Horse-power	Amperes on 110-volt line	Amperes on 220-volt line
¼	3	1.5	25	186	93
½	5.4	2.7	30	222	111
1	9	4.5	35	260	130
2	17	8.5	40	296	148
3	25	12.5	50	....	185
5	40	20	60	....	220
7½	58	29	75	....	275
10	76	38	85	....	312
15	114	57	100	....	366
20	150	75	....	....	....

The current taken by single-phase alternating-current motors can be found by noting the current taken by a direct-current motor of the same size and voltage, and dividing this current by the power-factor of the alternating-current motor. To find the current taken by each terminal of a three-wire, three-phase alternating-current motor, divide the current taken by a single-phase alternating-current motor of the same size and voltage by 1.73.

Example. What current is taken by a 5-horse-power, alternating-current, 220-volt, induction-motor of 80% power-factor?

Solution. A 5-horse-power, direct-current, 220-volt motor takes 20 amperes. A single-phase, 5-horse-power, 220-volt motor of 80% power-factor takes 20/.80 = 25 amperes.

Electric-Lighting Systems Commonly Used for Supplying the Electrical Energy to Lamps

Direct-Current, Constant-Potential Systems. The systems most used in America are:

(1) Two-wire system largely used for incandescent lighting from small plants, as for a large office-building or factory. It is usually operated at 110 volts.

(2) Three-wire system used in small towns for the lighting of buildings from the public mains, usually operated at 220 volts. Also in large cities with underground conduit-system. See pages 1466 to 1468.

Five-wire and seven-wire systems with high voltage have been used in Europe, but very little in America.

Alternating-Current, Constant-Potential Systems. There are two systems:

(1) Single-phase system. Current transmitted to building at from 1 000 to 2 000 volts and reduced to from 50 to 110 volts by a transformer. The term phase is used in connection with alternating-current systems only in the sense of circuit. Thus a single-phase system means an alternating-current system sending out power from one circuit only of the generator. A three-phase system has three circuits.

(2) Three-phase system. Three or four wires are used. This system is most used for lighting from public plants, principally because it enables both lights and motors to be operated from the public dynamo and is the most economical in wire. (See Table II.) Both of these systems are used for incandescent lighting and for power from central stations. For a comparison of a three-wire direct current with a three-phase, three-wire alternating current, see pages

168-9. An alternating current may be changed to a direct current at a sub-ation by a rotary converter or by a mercury-arc rectifier. The latter is very nerally used in garages in order to convert an alternating current into a direct rrent for charging storage-tteries.

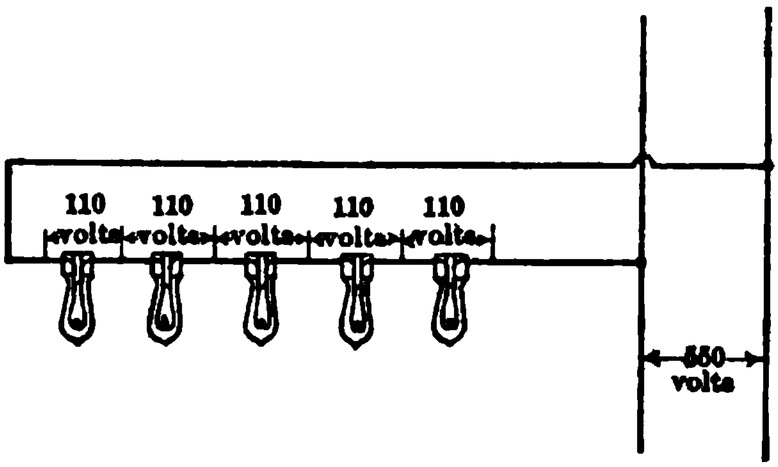

Fig. 3. Five Lamps in Series on a 550-Volt Line. Each Lamp has a Voltage of 110 Volts Across It

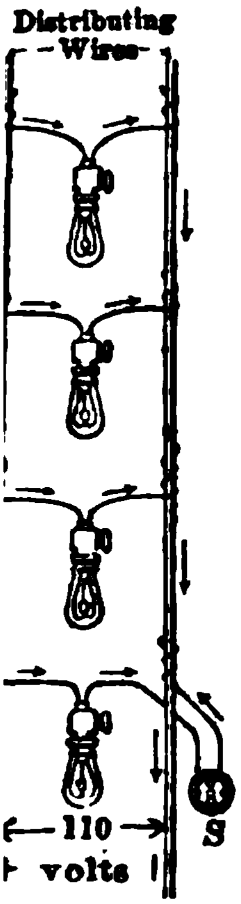
Methods of Connecting imps. There are three ways connecting lamps to the dis-bution-wires: (1) in series; in parallel; and (3) in rallel series.

(1) **Lamps in Series.** mps are said to be connected series when they are arranged after the other, so that same current flows through the lamps. The most com-n example of this system is the lighting of electric cars and the stations on electric-railway line. The voltage of such lines is usually 550 volts. Since ordinary incandescent lamp requires but 110 volts, five of these are placed eries as in Fig. 3. Each lamp now has a pressure of 110 volts across it, and the set of five lamps requires 550 volts across it, and so can be placed across the railway supply-wires. When lamps are arranged in series the total resistance of the circuit is the sum of the resistances of the several parts, and the voltage required to force the current through a number of lamps in series is the sum of the voltages required for the separate lamps. Thus the voltage required to supply the proper current for four 52-volt lamps is $4 \times 52 = 208$ volts. Arc-lamps for street-lighting are often connected in series, but incandescent lamps are very seldom connected in series except as described above or for decorative purposes or electric signs. Where lamps of low voltage, as in signs, etc., are used on 110-volt systems it is necessary to connect them in series. The underwriters do not approve connecting incandescent lamps in series. The series system requires that the same current flow through each lamp, and if one lamp burns out the circuit is broken and all of the lamps will go out, unless some provision is made for maintaining the circuit around the dead lamps.



L. Four Lamps Parallel. Each np Has the Full-Pressure of 110 ts Across It

(2) **Lamps in Parallel.** This is the common method of connecting incandescent lamps. It is illustrated in Fig. 4. With this system the pressure in each lamp is the same as in the distributing lines, and any lamp may be turned on or off without affecting the other lamps. For this system the PRESSURE or voltage must be kept constant, while the current or quantity of electricity flow-n the lines will depend upon the number of lamps that are burning. with twelve 16-candle-power lamps of 110 voltage on a parallel circuit, lamp requiring 0.51 ampere when all the lamps are burning, a current of amperes, or 673.2* watts, will be required. With but one lamp burning,

* Watts being equal to amperes times voltage.

a current of only 0.51 ampere will flow. The voltage, however, must be the same for one lamp as for the twelve. For lamps in parallel, therefore, a CONSTANT-POTENTIAL system is required. The current for lamps in parallel may be turned on or off at the lamp, or a switch-loop may be run any distance and the contact made by a switch (*S*) as for the lower lamp (Fig. 4).

(3) **Lamps in Parallel Series.** This method is a combination of the other two. Parallel lines are run as in the parallel system, but two or more lamps

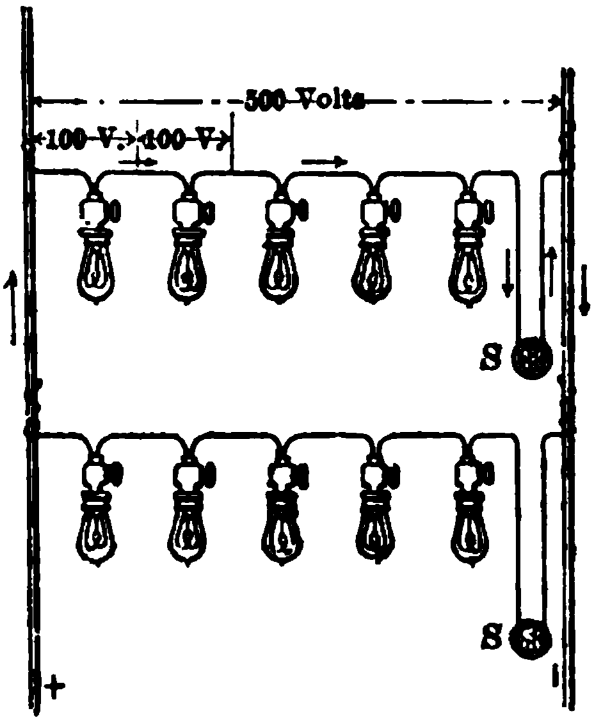


Fig. 5. Lamps in Parallel Series

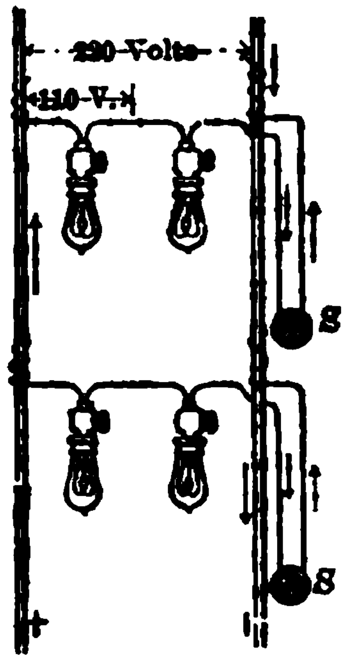

Fig. 6. Lamps in Parallel Series

are connected in series between them as in Figs. 5 and 6. This method of connecting lamps is used principally in places where it is desired to operate lamps on a power system. Fig. 5 shows a series of five lamps operated on a 500-volt system and Fig. 6 a series of two lamps on a 220-volt system using 110-volt lamps. Any number of series may be connected across the mains, each series being independent of the others. But in each series if one light burns out, the others in the same series will be useless, and one lamp alone cannot be used. The sum of the voltages of the lamps in series must be approximately equal to the voltage between the mains. There are a number of special cases in which this method of connection may be used.

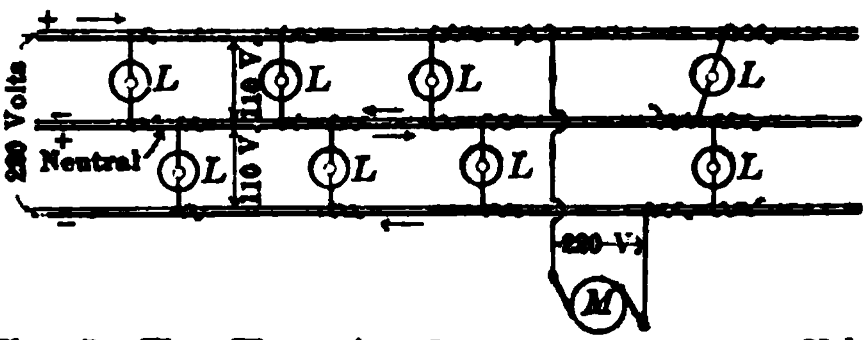

Fig. 7. The Three-wire Edison System. 220 Volts Between Outside Wires; Only 110 Volts Between Either Outside Wire and Neutral Wire

The Edison Three-Wire System. Figs. 4, 5 and 6 are examples of the two-wire system of distribution, which is the system recommended for average-sized office-buildings, apartment-houses, theaters and stores. Where power for motors is to be taken from the same plant as the lighting current, and where the power is not too great a portion of the capacity of the installation, this two-wire system may also be used. Separate mains, however, should under all circumstances be run for the motors, as the variation in load and, consequently, the current-demand on the mains would cause a very appreciable fluctuation in

andle-power of the lamps, if on the same mains with the motors. Where com-paratively long lines are required and the amount of current to be supplied is

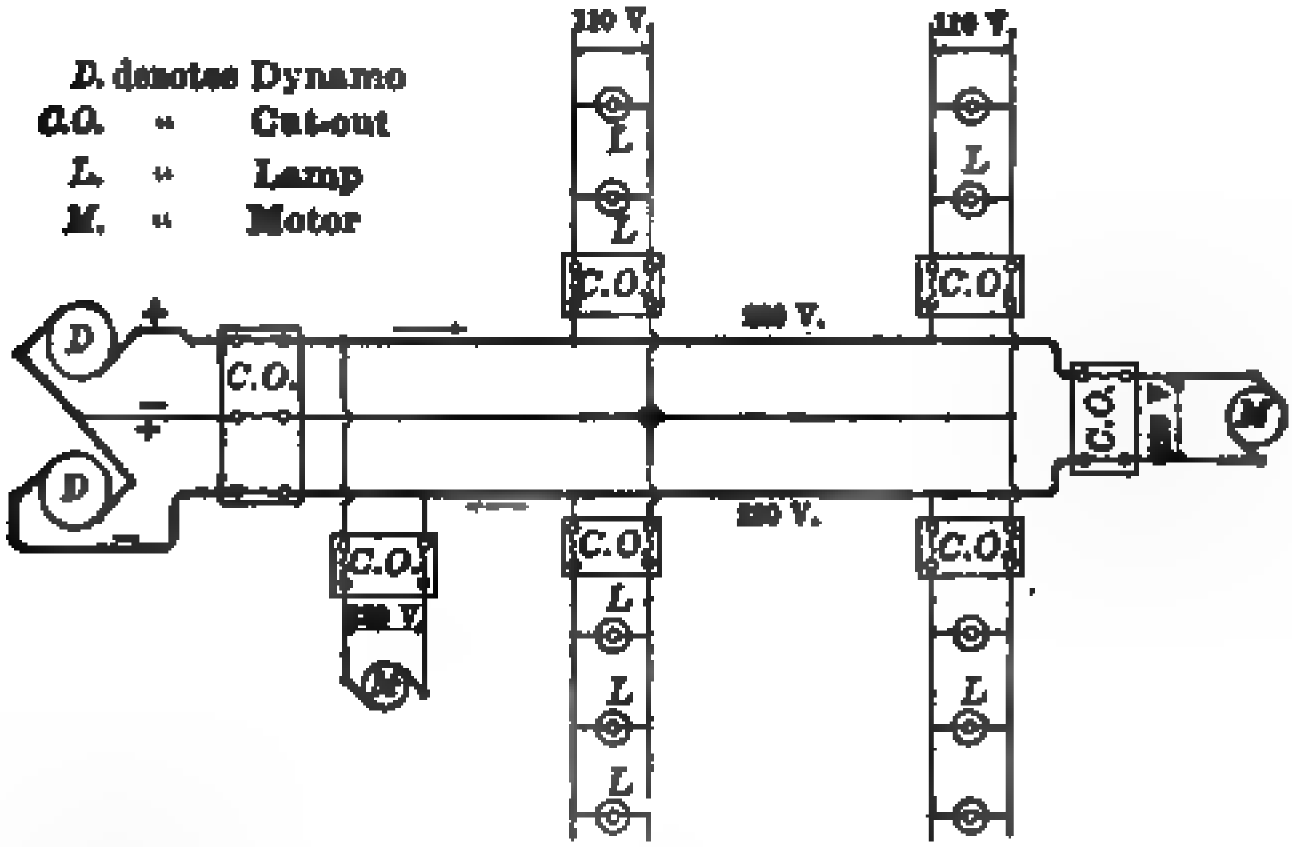

Fig. 8. Example of Three-wire System of Wiring

ge the THREE-WIRE SYSTEM is used. By this system two voltages or pressures be supplied, 110 and 220 volts being those generally adopted, the 110-volt uit supplying the arc and andescent lights and the -volt circuit the motors. . 7 shows how the wires run and connections le. The pressure between two outside wires is the voltage transmitted from generator, usually 220 s for interior wiring. current in these two s flows in opposite direc-s. The middle wire, d the NEUTRAL WIRE, a one side of two cir-, the current from one it tending to flow in direction and that from ther circuit in the oppo-direction; consequently currents of the same gth, in amperes, are ig in both circuits they alize each other in the e wire and there will current flowing in this

Fig. 9. The Wiring of a Cabinet. Showing How to Divide a Three-wire System into Six Two-wire Circuits, Three Circuits to Each Leg

With a current of 10 amperes flowing in one circuit and one of 6 es in the other circuit, the current flowing in the neutral wire will be 4

amperes. To obtain the greatest benefit from this system, it should always be installed so that there will be nearly the same load or number of lamps on each side of the neutral wire. Even then there will be times when more lamps will be burning on one side than on the other, so that it is necessary to give some size to the neutral wire. The neutral wire is seldom made less than one-half the cross-section of the outer wires. For distributing mains in buildings carrying lamps only, the neutral wire should be of the SAME SIZE as the outer wires. From Table II it will be seen that the three-wire system effects a considerable saving in copper, amounting to fully 60% of the ordinary two-wire 110-volt system. As a rule, in supplying current for light and power from one plant, the main wires only are arranged on the three-wire system and the distributing wires are run on the two-wire system as in Fig. 8. When using the three-wire system for lighting only, the three wires are usually run no farther within the building than to the centers of distribution, and from these centers two wires are run for each circuit, the circuits being divided as equally as possible on the two sides of the three-wire system as shown by Fig. 9. Three-wire mains are now very commonly used where the current exceeds 100 amperes. When motors are operated from the three-wire system they are usually connected only to the outside wires. Motors used on three-wire incandescent-lighting systems should be wound for 220 volts.

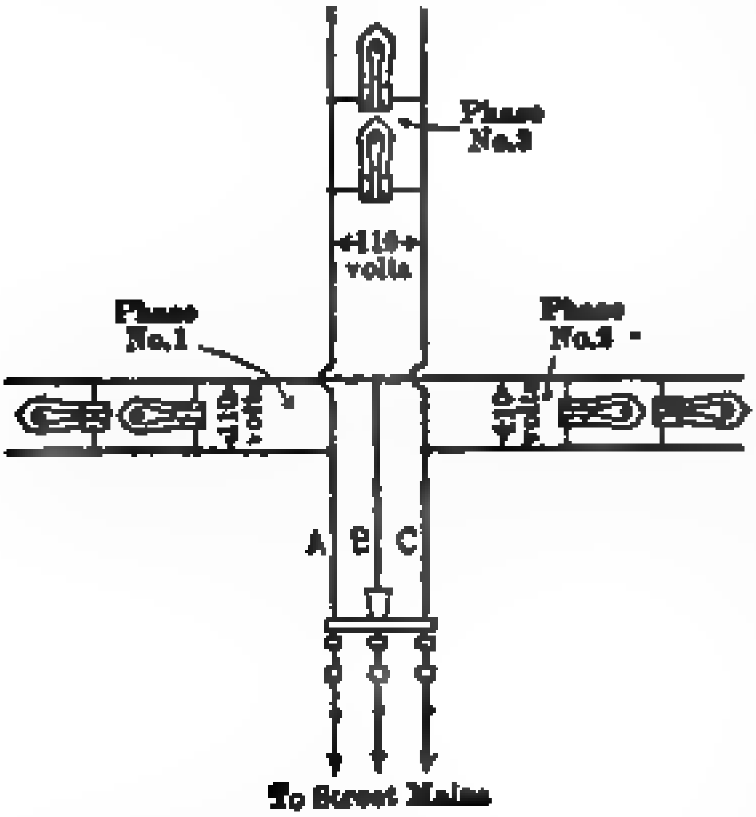

Fig. 10. Three-phase, Three-wire System, Alternating Current. Compare with Fig. 11

Fig. 11. Three-wire System, Direct Current. Compare with Fig. 10

Comparison of the Three-Phase and Three-Wire Edison Systems. The wiring for the Edison three-wire direct-current system is the same as that for the three-wire, three-phase alternating-current system, the only difference being that the voltage BETWEEN ANY TWO WIRES of a three-phase system is the same Thus in Fig. 10 which represents a three-wire, three-phase system the voltage between the wires *A* and *B* (phase No. 1)

110 volts; between B and C (phase No. 2) is 110 volts; and between A d C (phase No. 3) is 110 volts. But in Fig. 11, which represents a threere direct-current system, in which the voltage across A and B, and B and is 110 volts, the voltage across A and C is 220 volts or twice that across her leg.

Table II. Relative Weight of Copper Required in Different Systems for Equal Effective Voltage

Direct-current, ordinary two-wire system	1.000
Direct-current, three-wire system, all wires of same size	0.375
Direct-current, three-wire system, neutral, one-half size	0.313
Alternating-current, single-phase two-wire system	1.000
Three-phase three-wire	0.750
Three-phase four-wire	0.333

Wire-Calculations

Vire-Gauges.* As the diameter of wires is ordinarily designated by the nber of a wire-gauge, and as there are a number of wire-gauges in common use, ie knowledge of those used for copper wire is necessary. The Brown & Sharpe, 3. & S., gauge (see page 1474) is almost exclusively used in America in connec- with electrical work, except where the size of the wire is designated in cirır mils. The sizes of wire given by this gauge range from No. 0000 (0.46 in) Vo. 40 (0.0031 in), but No. 14 is the smallest size permitted for interior wiring. No. 10 wire has a diameter of about 1/10 in and its resistance per 1 000 ft ery nearly 1 ohm. For any given number of this gauge a wire three numbers ier has very nearly half the cross-section, and one three numbers lower has e the cross-section; thus a No. 13 wire has very nearly one-half the crossion of a No. 10 wire, and a No. 7 has twice the cross-section of a No. 10, our times that of a No. 13.

he Circular-Mil Wire-Gauge. This gauge was designed by the engineerdepartment of the Edison Company especially for the designation of copper for electrical work, and is now in general use in this country. In practice B. & S. gauge is commonly used for designating wires up to No. 0 or No. 00, all wires above that size are designated by circular mils (c.m.). The size ire required is often determined in circular mils and designated by the correding B. & S. gauge-number, which is readily done by means of Table III, 1473. Copper wire is sold by the pound if bare or of the numerous her-proof varieties, but rubber-covered wire is sold by the 1 000 ft.

ie basis of the circular-mil gauge is the area of a wire 1/1000 in in diameter il = 0.001 in); consequently, 1 c.m. = 0.0000007854 sq in. As the areas of es vary as the squares of their diameters, it follows that the sectional area vire 2 mils in diameter = 4 c.m., of a wire 10 mils in diameter 100 c.m., and 1.

hen wires are designated by circular mils, the SECTIONAL AREA and not the eter is generally given, c.m. always referring to sectional area. The diamof a wire in MILS OR IN THOUSANDTHS OF AN INCH = square root of its area RCULAR MILS.

us the diameter of a wire of 3 600 c.m. = 60 mils, or 0.060 in.

e diameter of a wire 14 400 c.m. = 120 mils = 0.12 in.

e area of a wire 0.162 in in diameter, or 162 mils, $= 162^2 = 26\,244$ c.m.

* For other gauges, see pages 401, 402, 403, 1473, 1509, 1510, 1512 and 1600.

To reduce circular mils to square inches. Multiply by 7 854 and point off ten places of decimals. Thus, 5 000 c.m. = 7 854 × 5 000 = 0.0039270000 sq in.

To obtain the sectional area of a square or rectangular bar in circular mils. Multiply together its dimensions in mils and the product by 1.273.

Example. What is the sectional area in circular mils of a bar ⅛ in × ¼ in?

Solution. ⅛ in = 0.125 in = 125 mils, ¼ in = 0.250 in = 250 mils; 125 × 250 × 1.273 = 39781.25 c.m.

The weight of bare copper wire per 1 000 ft = c.m. × 0.003027 lb. Thus the weight of 1 000 ft of copper wire having a sectional area of 2 000 c.m. = 0.003027 × 2 000 = 6.054 lb. Table IV, page 1474, gives the dimensions and weights of bare copper wire from No. 18 to No. 0000 B. & S.

Carrying Capacity of Copper Wire. The safe carrying capacity of copper wire for interior wiring is practically fixed by the underwriters, and if the capacity-limits given in the table published by them are exceeded it would tend to destroy the right to recover insurance in case of fire. The safe carrying capacity of rubber-covered and weather-proof wires given by the National Board of Fire Underwriters is shown by Table III, page 1473. The lower ampere-capacity assigned to rubber-covered wires is due to the fact that the rubber insulation would deteriorate in quality under a temperature as high as that allowed for weather-proof wire; that is, the rubber covering makes necessary a lower rate of heat-development than is required for safety from fire. No wire smaller than No. 14 may be used under insurance-rules, except that No. 16 may be used for flexible cord and No. 18 for fixture-wiring. Nos. 13, 11, 9 and 7 are not usually carried in stock and can only be purchased on special order. Rubber-covered wire must be used for service-wires, for molding-work and in damp places; it is more expensive than weather-proof wire. The latter wire may be used in open or exposed places and for outside line-wires.

Drop of Potential. When an electric current flows through a wire of any appreciable length the pressure becomes reduced by the resistance of the wire, so that if the current enters the wire at, say, 110 volts, at the extreme end of the circuit it will be somewhat less, depending upon the length and sectional area of the wire. This loss in voltage is called DROP OF POTENTIAL. Drop of potential corresponds to LOSS OF HEAD in hydraulics. As a drop of voltage materially below that for which the lamps are designed means diminished candle-power, it is very important that the wires be proportioned so that the drop shall not be sufficient to affect the illumination. The table for safe carrying capacity for wires has nothing to do with the drop of potential which these currents will cause in the wires. Accordingly, mains and distributing wires may be capable of carrying the number of amperes in accordance with Table III, page 1473, and yet cause a drop of potential of such magnitude that the most distant lamps will burn only at a dull red. It is therefore necessary, in computing the size of these mains and distributing wires, to consider two things:

(1) That the wire is large enough, according to the underwriters' table, to carry the current safely.

(2) That the potential drop from the generator to the farthest lamp shall not be excessive. An excessive drop in voltage also means increased cost for light and not enough copper in the wires.

Where the current is supplied from the public mains it is usual to specify a 2% drop, but where the current is produced cheaply, as by a dynamo on the premises, a 3% or 5% drop may be allowed. Not more than a 5% drop on short distances should be permitted, even where very cheap work is desired. The

drop in volts (not in percentage) = current in line × resistance of line, or drop
n volts = amperes × ohms.

Example. What will be the drop in a circuit of No. 14 copper wire 280 ft
ong, supplying nine lamps, requiring 4.5 amperes?

Solution. From Table IV, page 1474, it is found that the resistance of No.
4 wire is 2.527 ohms per 1 000 ft; hence for 280 ft it will be 2.527 × 0.280 =
.7075 ohm, and drop in volts = 4.5 × 0.7075 = 3.1837 volts. The voltage for
his current (0.5 ampere per lamp) will be about 110; consequently the per-
entage of drop = 3.1837/110 = 2 9/10%, nearly. A 2% drop on a pressure of
10 volts is 2.2 volts.

Load-Center. The meaning of this term may best be illustrated by an exam-
le. Let Fig. 12 represent a circuit carrying six lamps, the first lamp being

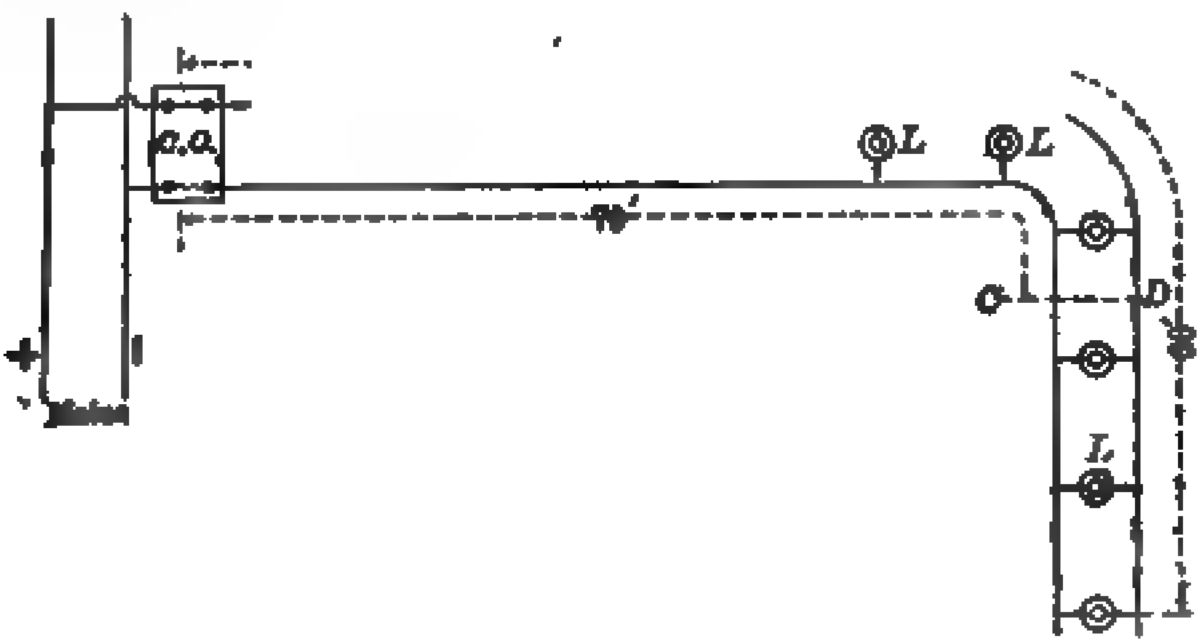

Fig. 12. The Point *D* is the Load-center

ft from the cut-out, or source of supply. The whole of the current must be
nsmitted through this 40 ft, but from that point it will gradually fall off, and
average current will only extend to the point *CD*, halfway between the
reme lamps. Or, in other words, the load-center is analogous to the center
gravity of the lamps on the circuit. The load-center determines the length of
line in the rules for finding the necessary size of wire.

Distributing Centers are the points in a building where the cut-out cabinets
located and the branch circuits taken off.

Calculations for Size of Wire for Incandescent Lighting. The sizes of
s for interior lighting are or should be always determined on a basis of a fixed
p of potential, usually 2 volts on the distributing circuit and from 2 to 3
s on the feeders or mains.* The size of wire may be determined either in
s of its sectional area in circular mils or in terms of its resistance in ohms
1 000 ft. Knowing the sectional area in circular mils, one may find the
esponding gauge-number from Table III, page 1473, or if the resistance in
s per 1 000 ft is known, the corresponding gauge-number may be found
Table IV, page 1474.

* Many municipal lighting companies require that there shall be no more than 2%
drop in the wiring for interior lighting.

The formula for circular mils is as follows:

$$\text{Circular mils} = \frac{10.4 \times 2d \times N \times c}{v} \tag{1}$$

The formula for resistance per 1 000 ft of wire is

$$\text{Resistance} = \frac{1\,000\,v}{N \times c \times 2d} \tag{2}$$

In both these formulas d = distance in feet, one way, from cut-out to load-center (see page 1471) for distributing wires, or from entrance cut-out or source of current to distributing center for main lines or feeders. c = current in amperes PER LAMP. N = number of lamps supplied. v = drop in volts. Both formulas apply to any voltage and to any two-wire system. To use these formulas for the ordinary three-wire system, let N = maximum number of lamps on ONE SIDE of the neutral wire and DOUBLE THE DROP IN VOLTS. The neutral or middle wire should be of the same size as the outside wires.

Example. The distance from the cut-out to load-center of a circuit carrying sixteen 40-watt, 110-volt lamps is 50 ft. What size of wire should be used for a drop of 2 volts?

Solution. $d = 50$; $N = 16$; $c = 40/110 = 0.364$; and $v = 2$.
By Formula (1),

$$\text{Circular mils} = \frac{10.4 \times 100 \times 16 \times 0.364}{2} = 3\,030$$

Table III, page 1473, shows that the next larger size of wire is 4 107 c.m., equivalent to a No. 14 wire.
By Formula (2),

$$\text{Resistance per 1 000 ft} = \frac{1\,000 \times 2}{12 \times 0.364 \times 100} = 4.59$$

which we see from Table IV, page 1474, is about the resistance of a No. 16 wire; but as No. 14 is the smallest wire permitted that size must be used.

Example. The distance from the entrance cut-out, where the wires enter the building, to the main distributing center of a building is 100 ft. The total number of 16-candle-power, 110-volt carbon-lamps supplied is ninety. What is the size of the mains that should be used on the two-wire system with a drop of 2 volts? (A 16-candle-power 110-volt carbon lamp takes approximately 0.51 ampere.)

Solution. $d = 100$; $N = 90$; $c = 0.51$; $v = 2$
By Formula (1),

$$\text{Circular mils} = \frac{10.4 \times 200 \times 90 \times 0.51}{2} = 47\,800$$

In Table III it is seen that No. 3 wire must be used. If a drop of 3 volts is allowed the sectional area required will be 33 048 c.m., which requires a No. 5 wire. The weight per 1 000 ft of No. 3 weather-proof wire (Table IV) is 200 lb and of No. 5 wire 125 lb; consequently, the SAVING IN WEIGHT OF WIRE by using a drop of 3 volts instead of 2 is 75 lb, or 37½% of 200, and as wire is sold by the pound, the SAVING IN COST with a 3% drop ranges from 30 to 40% of a 2% drop.

Example. With the same conditions as given in the preceding example what is the size of the wire that will be required for the ordinary three-wire system with 2% drop?

Table III. Carrying Capacity of Wires and Cables

FOR INTERIOR CONDUCTORS, ALL VOLTAGES

From the National Electrical Code

No. of wire, B. & S. gauge *	Circular mils	Capacity in amperes

"	2 000 000	1 050	1 670

A current of one ampere will supply two 16-candle-power carbon lamps.

olution. In this case we use one-half of N, or 45, and $2\,v$ instead of v; then

$$\text{Circular mils} = \frac{10.4 \times 200 \times 45 \times 0.51}{4} = 11\,920$$

just ONE-FOURTH the section required for the two-wire system. The size vire required is No. 8; a No. 9 would answer if it could be had. Comparing weight of wire required with the two-wire system gives two No. 3 wires ghing 400 lb per 1 000 ft, and with the three-wire system three No. 8 wires ghing 207 lb; hence, the saving in cost is nearly 50% and if No. 9 wire were inable the saving would be 55%. With a drop of 3% (3.3 volts) the cir- r mils required for the three-wire system $= \dfrac{10.4 \times 200 \times 45 \times 0.51}{6.6} = 7\,230$,

* For other gauges, see pages 401, 402, 403, 1469, 1509, 1510, 1512, and 1600.

requiring No. 10 wires. The current in amperes in the two-wire system $= N \times c = 45.9$, and in the three-wire system $\frac{1}{2} N \times c = 22.95$. Referring to Table III it is seen that the smallest size of weather-proof wire permitted for 45.9 amperes is No. 8; consequently, No. 8 wire could be used with the two-wire system and comply with the underwriters' rules, but the drop in potential would be $45.9 \times 0.2 \times 0.6285$ (amperes × resistance of line) $= 5.77$ volts; or over 5%.

For the three-wire system, the current being 23 amperes, the smallest weather-proof wire permitted by Table III is No. 12, which would give a drop of 7.4 volts, or 3.8 volts on each side, or about 3½% of the lamp-voltage. Except on very short lines a 2% drop will always demand larger wires than required by the underwriters, and this is also usually true of a 3% drop.

Table IV. Dimensions, Weights and Resistances of Copper Wire

* Approximate weight of weather-proof line-wire for outdoor work is 10% less than here given.

To find the smallest size of wire that will comply with the underwriters' rules it is only necessary to compute the total current in amperes, and from Table III select the wire having a capacity equal to or next above the required number of amperes. Table VI shows at a glance the maximum number of 16-candle-power 110-volt carbon lamps permitted by the National Code.

Formulas (1) and (2), page 1472, may also be used for MOTOR-WIRING, if the required current in amperes is known, by substituting the given number of amperes for $N \times c$.

Table V. Maximum Length of Line for Given Number of Lamps that can be Used with a Two-Per-Cent Drop. Two-Wire System

Based on ½ ampere per carbon-lamp. One 32-candle-power carbon-lamp = two 16-candle-power carbon-lamps. Four 40-watt tungsten-lamps = three 16-candle-power carbon-lamps

No. of wire, B. & S. gauge	Number of 16-candle-power, 110-volt carbon-lamps								
	4	6	8	10	11	12	16	20	24

1	.....	.....	.....	.....	285	243	213	190	170

For three-wire mains with 220 volts between outer wires and same number of lamps on ch side, length of wire may be increased four times.

Table VI. Maximum Carrying Capacity of Wires in Terms of 16-Candle-Power 110-Volt Lamps, However Short the Wires May Be

Based on ½ ampere per lamp
Four 40-watt tungsten-lamps = three 16-candle-power carbon-lamps

No. of wire, B. & S. gauge	Number of lamps		No. of wire, B. & S. gauge	Number of lamps	
	Rubber-covered	Weather-proof		Rubber-covered	Weather-proof
14	24	32	4	130	184
12	34	46	3	152	220
10	48	64	2	180	262
8	66	92	1	214	312
6	92	130	0	254	370

Example. What should be the size of the wires to be run to a motor that requires 30 amperes at 220 volts and is situated 200 ft from the distributing pole, the drop in volts not to exceed 2%?

Solution. Using Formula (1), and substituting 30 for $N \times c$, we have

$$\text{Circular mils} = \frac{10.4 \times 400 \times 30}{4.4} = 28\,400$$

which requires a No. 5 wire. Either the watts or the current in amperes is stamped on every motor. If watts are given, the current in amperes may be found by dividing the watts by the voltage. If kilowatts are given, multiply by 1 000 and then divide by the voltage.

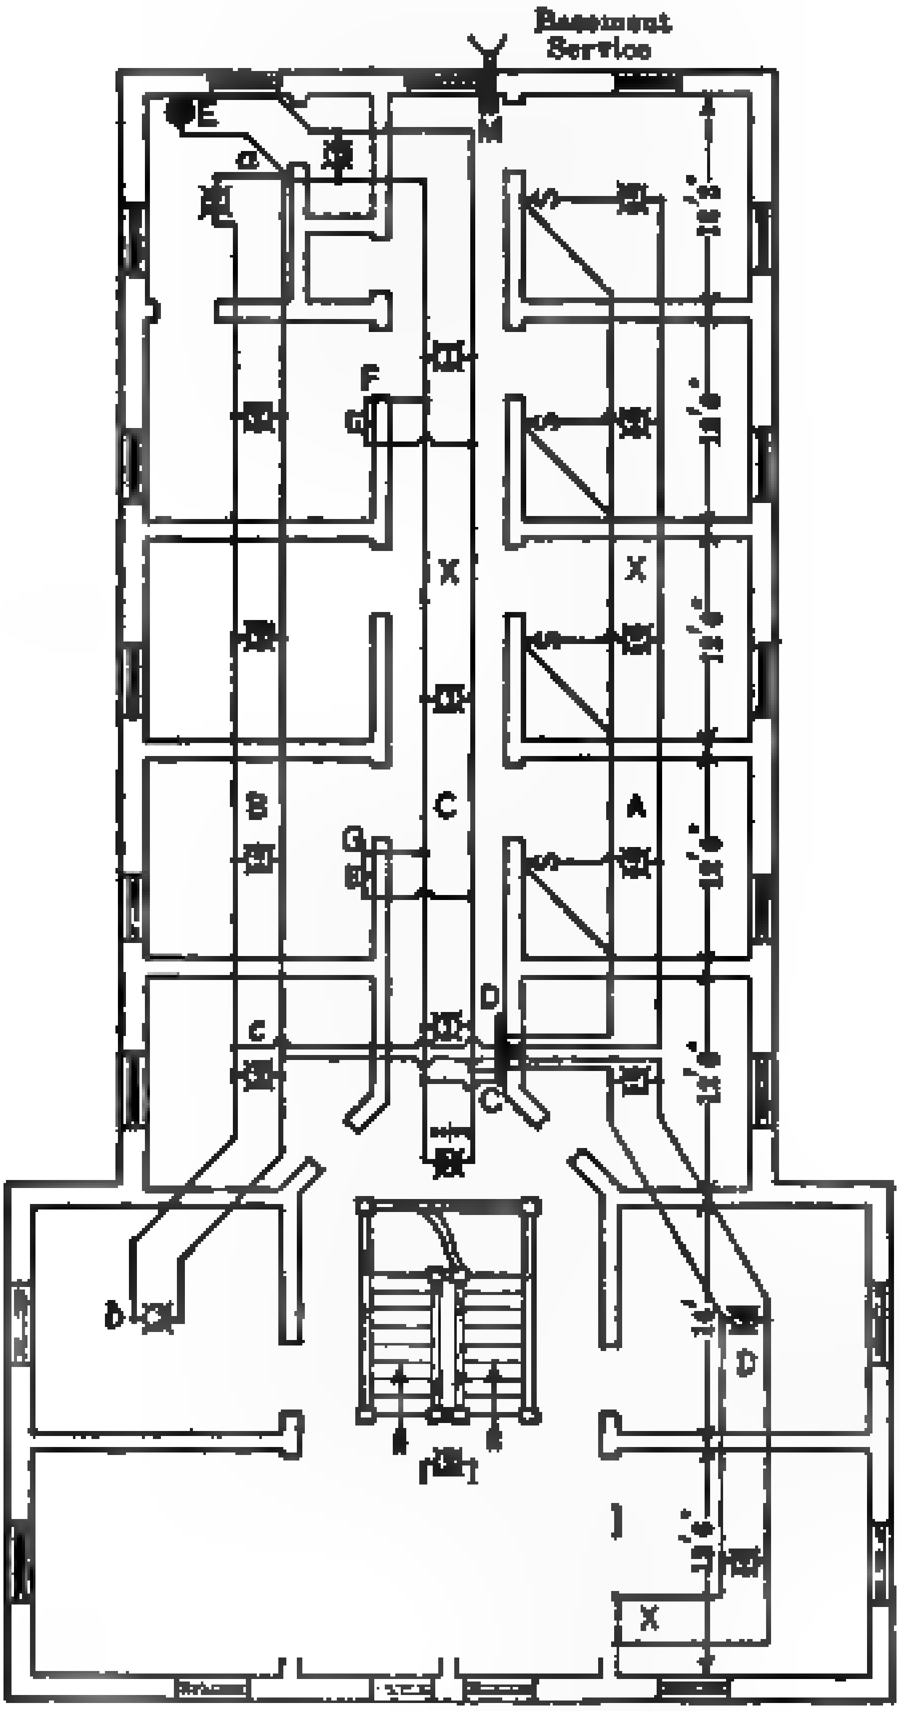

Fig. 1[illegible]. Wiring-diagram for Second Story. For Meaning of Symbols, see pages 1484–5.

Wiring-Tables. Several forms of wiring-tables which are very useful to electricians are published in various books on electricity. For ordinary interior wiring for 110-volt, 16-candle-power carbon-lamps, Table V, computed by Mr. Kidder, will show at a glance the number of wire, B. & S. gauge, required to supply the given number of lamps by first ascertaining the length of line (one way) through which the average current flows, as explained under LOAD-CENTER. (See page 1471 and Fig. 12.)

Simple Example of Wiring. To show the method of wiring an ordinary building for incandescent lighting we will take a two-story building having a floor-plan as shown in Fig. 13. Most of the light-outlets are on the ceiling and are indicated by a small circle. The outlet marked *E* is a special outlet for heating, etc., and must be described in the specifications. Let us assume it is to take 320 watts. This is equivalent to adding eight 40-watt lamps to this circuit. *F* and *G* are wall-outlets. The meanings of the symbols used are explained on pages 1484–5. The numbers

nd 2 inside the circles denote the number of 16-candle-power carbon-lamps .he outlet. The same number of 25-watt or 40-watt tungsten-lamps may ays be used without overloading the circuits. See pages 1398 and 1399 Standard-Wiring Symbols. The current to be obtained from the wires of public lighting company, which carry a current at 220 volts between the side wires, and at 110 volts between either outside wire and the neutral e. The feed wires for the building should enter through the alley-wall at ıut the level of the second ır and should drop in the tition just inside the wall the main fuse-block and tch, which should be in small cabinet and the .er (*M*). The distribu-ı-cabinet should be lo-ed near the center of the lding, say at *DC*, and re should be a cabinet each story. From this inet we will run four cir-s for each story, which indicated by the letters *B*, *C* and *D*. Circuit *A* ws the wires run for a .ch on the wall near the r of each of four rooms ontrol the lights in those ns. All of the lights on uit *C* shou'd be controlled ceys in the lamp-sockets. The lights on circuits *B* and *D* are not switched, ·pt the outlet at head of stairs, which is controlled by a snap or push-button ch at *S*. For a first-class job all of the four circuits would be controlled cnife-switches in the cabinet, as shown in Fig. 14, but this is not absolutely ssary.

F.F. FUSE-PLUGS S.S. KNIFE-SWITCHES

Fig. 14. Cabinet-wiring for Knife-switch Control

ize of Wires. The load-center of circuits *A*, *C*, and *D* would be at about points marked *X* (Fig 13). For circuit *B* take one-half the distance *ab* add to it the distance from *c* to the cabinet In figuring the length ne, 6 ft should be added for the drop from ceiling to the cabinet. Let us as-e that tungsten-lamps are to be used In computing the current taken by ı lamp it is always assumed that no smaller than a 40-watt tungsten is used. drop-lights, marked ○ would probably be 25-watt lamps, but must be ıted as 40-watt, according to the underwriters' rules. The number of 40-: lamps and length of wire for each circuit are as follows:

Circuit *A*, 8 lights, 41 ft one way to load-center.
Circuit *B*, 11 lights, 52 ft one way to load-center.
Circuit *C*, 16 lights, 37 ft one way to load-center.
Circuit *D*, 12 lights, 59 ft one way to load-center.
Total number of lamps, 47.

·om Table V we see that the maximum length of line one way for No. 14 carrying twelve carbon or sixteen 40-watt lamps is 70 ft. Consequently, f the lamp-circuits can be No. 14 wire, which is the smallest size permitted.

Feed-Wires. These should be run on the three-wire system. Allowing for 2×47 or 94 lamps in first and second stories and eight in basement, the feed-wires must be capable of supplying 102 lamps. Each 40-watt lamp would take $40/110 = 0.364$ ampere. The distance from outside the building to distribution-cabinet is about 72 ft, allowing for three drops. Using Formula (1), and assuming that there will be fifty-one lamps on each side of the three-wire system, and doubling the drop in volts, gives

$$\text{Circular mils} = \frac{10.4 \times 144 \times 0.364 \times 51}{4} = 6\,960 \text{ c.m.}$$

which calls for No. 11 wire; but as this size is not carried in stock we must use No. 10. From the second story to the third No. 12 wires could be used. For almost all buildings lighted from a central station the lamp-circuits will not usually require a wire larger than No. 14, so that about the only wires which the architect needs to look after are the wires which run to the distribution-cabinets.

Switches. A switch is a device for opening or closing a circuit at will either at the fixture or at any other point. In the better class of buildings the majority, if not all, of the ceiling-lights are controlled by switches placed at a convenient place on a side wall. Lights may be controlled at any distance from the fixture by running a switch-loop. For controlling either a single lamp or fixture, or any number of lamps, a switch-loop is run as shown on circuits *A* and *C*, as in Fig. 13. As shown also in Fig. 4, one side of the loop must be connected with one of the distributing

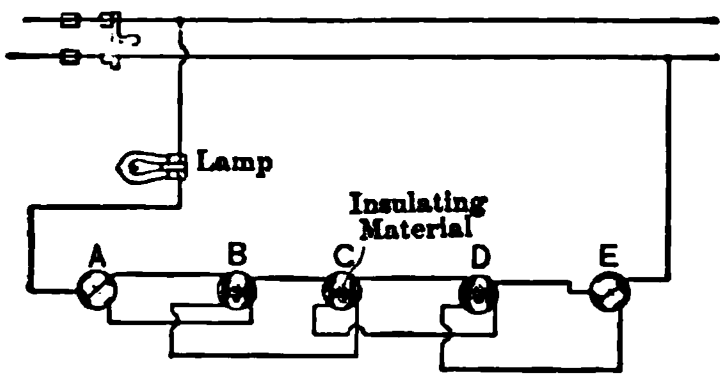

Fig. 15. The Lamp May Be Turned Off or On From Any of the Five Points, *A*, *B*, *C*, *D*, or *E*

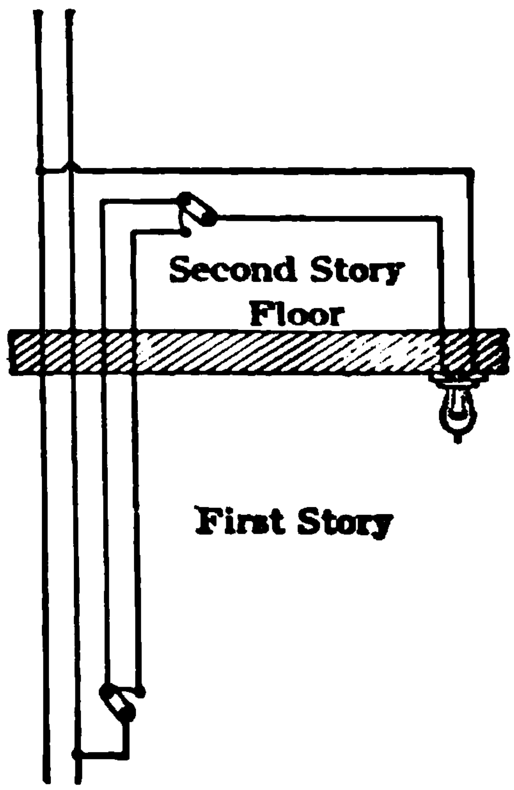

Fig. 16. The Lamps May Be Turned Off or On From Either the First or Second Story

wires and the other side to the lamp. When a number of lamps are to be controlled by one switch, as in the case of hall-lights, and the lamps in large rooms, such as churches, theaters, concert-halls, etc., a separate circuit is usually run for those lamps, and a switch anywhere in one of the distributing lines will turn on or off all of the lights on that line. As the underwriters do not permit more than twelve 16-candle-power carbon or sixteen 40-watt tungsten-lamps on one circuit, not more than these numbers of lamps can be controlled by one switch, except where the switch is placed on the mains. It is also practicable to control one lamp from two or three places. Thus by a duplex or three-point switch and proper wiring, a lamp may be lighted or turned off from either the first or second story at will. By means of two three-point switches and one four-point switch a first-story hall-lamp may be

controlled at will from either the first, second or third stories. Fig. 15 shows the method of control from any number of points, since any number of 4-point snap-switches, such as *B*, *C* and *D*, can be inserted between the 3-point switches *A* and *E* if more points of control are needed. Fig. 16 shows one method of wiring for controlling a hall-light from first and second stories by means of two 3-point switches. With the switches in the position shown the circuit is broken, as there is no connection between the lamps and line *B*. By turning either switch a connection is made with line *B* and the current will flow.

Kinds of Switches. For controlling lamps from one point three kinds of switches are used, namely, SNAP-SWITCHES, FLUSH or PUSH-BUTTON SWITCHES and KNIFE-SWITCHES. When less than eight lamps are controlled by the switch, flush or push button switch is commonly used where a neat appearance is desirable, and in places where this is of no importance, a snap-switch is used, as it is the cheaper. Where a circuit of twelve or more lamps is controlled by a switch, a double-pole (d p.) knife-switch (Fig. 17) is commonly used, being generally placed in a cabinet. Knife-switches should always be used on main wires. Snap and push-button switches are made both single and double pole. A SINGLE POLE switch opens only one side of the circuit and a DOUBLE-POLE switch both sides. A double-pole knife-switch necessarily opens both sides. A switch used on a three-wire system must have three poles. Double-pole snap and push button switches are seldom used for less than twelve lamps. DUPLEX SWITCHES, sometimes called THREE-POINT SWITCHES, are usually of the snap or of the push-button type.

Fig. 17. Common Knife-switch

Conduit-Systems. As weather-proof or rubber-covered wire cannot be run in brick walls or floors of brick, terra-cotta, or concrete without some protection other than the covering of the wires, it is necessary in such places to run the wires in tubes or conduits, and in fire-proof buildings all of the lighting-wires are generally run in a system of conduits.

Kinds of Conduits. There are two kinds of interior conduits now in common use

(1) Lined Mild-Steel Pipe. The lining consists of a thin coat of enamel which must be impervious to water, sulphuric acid, acetic acid, hydrochloric acid and carbonate-of-soda solutions. For regular conduit systems only mild-steel piping of the same thickness as ordinary gas-piping is approved by the Underwriters. The conduit must be continuous from outlet to outlet or junction-boxes or cabinets and must properly enter and be secured to all fittings, and the entire system must be mechanically secured in position. Mild-steel pipe may be galvanized, coated, or enameled on the outside, but it must be enameled on the inside as stated above Rigid conduit, WHETHER LINED OR UNLINED, are installed in the same manner as a good job of gas-fitting, except that for conduits the pipe may be bent to a curve and no elbow can be used having less than 3-in radius for the inner edge Wherever branches are taken off, junction-boxes must be provided and every outlet must have an approved outlet-box or plate. The wire drawn into conduits must be of at least No 14 size, rubber-covered and with double braid. All conduit-systems must be GROUNDED by connecting the steel pipe by a conductor to the gas or water system.

(2) **Flexible Armored Conduit.** This is made of metal ribbon wound spirally, is generally used in wiring old houses because it is easier to install. CIRCULAR LOOM is flexible woven tubing treated with insulating material that makes it hold its shape. This may be used in dry places and for outlets through plastering if it extends back to the nearest porcelain knob holding the wire which the conduit covers.

National Electrical Code. The National Board of Fire Underwriters, in conjunction with committees from the American Institute of Architects, and from the national associations of electrical, mechanical and railway engineers, have prepared a code of rules and requirements for the installation of electrical lighting which is the generally recognized standard and with which all interior wiring must comply if it is desired to obtain insurance on the building. This code has also been made a part of the ordinances of most of the larger cities. It is revised every two years, in the odd-numbered years. The National Board of Underwriters also publishes, semi-annually, a SUPPLEMENT to the National Electrical Code which contains a list of all articles that have been examined and approved for use in connection with the code, together with the names of the manufacturers. Articles not included in this list will not be passed by the inspectors. Copies of the code and supplement can be obtained from the nearest Underwriters' Inspection Bureau, or by writing to the Underwriters' Laboratories, 382 Ohio Street, Chicago, Ill. The following requirements apply to almost every installation, and every architect should be conversant with them.

Extracts from the National Electrical Code*

(1) All wire for concealed work must be of the best approved rubber-covered brands, as shown in List of Fittings. No wire smaller than No. 14 B. & S. gauge to be used. All wire run in conduits must have double-braid covering.

(2) Where wires are concealed and run parallel to joists they must be supported on porcelain knobs which hold the wires at least 1 in from woodwork or surface wired over. Knobs must be SECURELY FASTENED and MUST BE PLACED EVERY 4½ FT. Where wires are run through joists they must be bushed with porcelain tubes the entire width of joists. All wires must be drawn tight, so as to have all slack removed.

(3) In concealed work all wires MUST BE SEPARATED FROM EACH OTHER BY AT LEAST 5 IN. Where wires run down partitions, especially partitions formed by 2 by 4-in studs, the wires must be so supported as to run in the middle of partition. If more than two wires are run down partition between studs, they must be separated by at least 5 in.

(4) Where wires pass through floors they must be protected from the floor up to a point 5 ft above the floor with conduit or with boxing. There must always be a space of 1 in between the wires and the boxing.

(5) All joints must be securely soldered and taped. A splice to be approved must be both mechanically and electrically secure without solder, but must be soldered unless made with some form of APPROVED splicing-device. Joints to be properly taped require, where rubber-covered wire is used, first to be taped with rubber tape and then with friction-tape. The insulation of a joint must equal that on the conductors.

(6) Where wires enter the building they must be provided with drip-loops.

(7) There must be a MAIN CUT-OUT AND SWITCH installed in an easily accessible place, as near as possible to the point where the wires enter the building.

* The numbers here given do not correspond with those in the code, and several of the rules are much abridged. They are intended to give the substance, rather than the exact language.

This will require that cut-out and switch be placed where there is no need of a 12-ft ladder to reach them. (See Fig. 18.)

(8) Every lighting-circuit of 660 watts must be protected by a cut-out. This will limit the number to twelve 16-candle-power or sixteen 40-watt lights on a two-wire, 110-volt circuit, and to thirty-two 40-watt or twenty 16-candle-power lights on a three-wire, 220-volt circuit. By special permission, where No. 14 wire is carried directly to keyless sockets, and where the location of the sockets s such as to render unlikely the attachment of flexible cords thereto, the circuits nay be so arranged that not more than 1 320 watts (or 32 sockets) may be de- endent upon the final cut-out. Sockets are to be considered as requiring not ess than 40 watts each.

(9) All cut-outs must be placed in an ASBESTOS-LINED CABINET. The as- estos must be at least 1/8 in in thickness and securely held in place by shellac nd tacks. Lumber of which cabinet is made must be at least 3/4 in in thickness. Cabinet must be furnished with snug-fitting door; door to be hung by strong inges and to be furnished with a suitable catch.

(10) Cut-outs to be approved must be of the plug or of the cartridge-type.

(11) Enclosed arc-lamps and incandescent lamps must not be placed on same rcuit. Arcs must be on separate circuits by themselves. Each arc-light must e protected by an approved cut-out. The cut-outs are to be placed in an as- estos-lined cabinet.

(12) The practice of using fused rosettes will not be approved, except in mills.

(13) Where wires run down the side wall they must be protected from me- anical injury.

(14) All outlets must be made to conform to Rule 24, National Electrical Code.

(15) Fans in series will not be approved.

(16) Runs of lamp-cord will not be approved. Lamp-cord is designed to be ed for drops only. Ordinary insulated wire must be run to place desired.

(17) Electric heaters must be installed in accordance with Rule 25 a–f, National ectrical Code.

General Suggestions for Electric Work *

General Principles and Recommendations. In all electric-work con- ctors, however well insulated, should always be treated as bare, to the end it under no conditions, sting or likely to exist, a grounding or short cuit occur, and so that leakage from con- tor to conductor, or ween conductor and und, may be reduced the minimum. In wiring special atten- must be paid to the mechanical execution of the work. Careful and t running, connecting, soldering, taping of conductors, and securing and ching of fittings, are specially conducive to security and efficiency, and will strongly insisted on. In laying out an installation, except for constant-cur- systems, the work should, if possible, be started from a center of distri- ion, and the switches and cut-outs, controlling and connected with the several iches, be grouped together in a safe and easily accessible place, where they be readily got at for attention or repairs. The load should be divided as

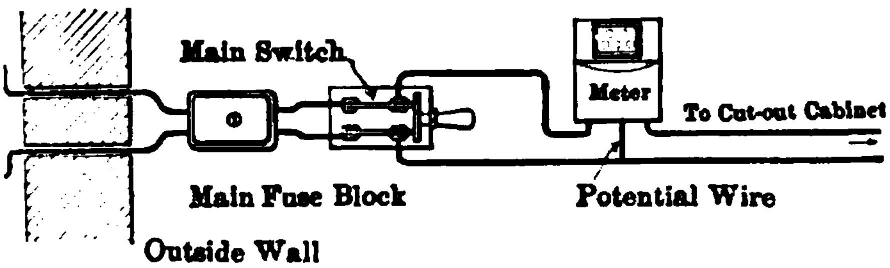

Fig. 18. Main Switch, Fuse-block and Meter Located Near the Point of Entrance of the Service-wires

* Preface to the National Electrical Code

evenly as possible among the branches, and all complicated and unnecessary wiring avoided. The use of wireways for rendering concealed wiring permanently accessible is most heartily indorsed and recommended; and this method of accessible concealed construction is advised for general use. Architects are urged, when drawing plans and specifications, to make provision for the channeling and pocketing of buildings for electric-light or power-wires, and in specifications for electric gas-lighting to require a two-wire circuit, whether the building is to be wired for electric lighting or not, so that no part of the gas-fixtures or gas-piping be allowed to be used for the gas-lighting circuit. Fig. 18 shows a common arrangement of main cut-out, switch and meter, to comply with Rule 7, page 1480. The main cut-out and switch should be as near as possible to the outside wall, but the meter may be at some distance from the switch if desirable for any reason.

Specifications for Interior Wiring*

Specifications for Interior Wiring should provide:

(1) That the wiring shall be installed in accordance with the latest rules and requirements of the National Board of Fire Underwriters, the local ordinances, and the rules of the local electric light company, where current is to be taken from the public mains.

(2) No electrical device or material of any kind to be used that is not approved by the Underwriters' National Electric Association, and all articles must have the name or trade-mark of the manufacturer and the rating in volts and amperes or other proper units marked where they may readily be observed after the device is installed.

Requirements (1) and (2) are sufficient to insure a SAFE installation.

(3) Contractor must obtain a satisfactory certificate of inspection from the city inspector or from the inspector of the local board of fire-underwriters.

(4) If the wires are to run in a conduit system it should be so specified. When a conduit system is used, THE WIRES SHOULD NOT BE DRAWN IN until all mechanical work as far as possible is completed. It is best to wait until after the plastering is dry. All conduit systems must be GROUNDED.

(5) Size of Wires. The best method is to specify the size of all wires, no wire to be less than No. 14 B. & S. gauge; but if the architect does not care to do this, the following clause is sufficient, provided he can have confidence that the contractor will comply with it: "All wires must be of such size that the drop in potential at farthest light-outlet shall not exceed 2% under maximum load."

(6) Cut-out cabinets and where they are to be placed; also location of main-line cut-out and fuse. For buildings containing not more than forty lights, one distributing point is generally sufficient, although in large houses it is often convenient to have a cut-out cabinet in each story.

(7) Number and kind of switches. All outlets should be marked on the plans, and the number of lights indicated by figures 1, 2, 3, 4, etc., as in Fig. 13. See pages 1484 and 1485 for standard symbols. The location of all switches for controlling lights should also be indicated on the plans.

Approximate Cost of Wiring for Incandescent Lighting. Approximate estimates of the cost of wiring buildings for electric lighting are usually based on the number of outlets (not lamps). The actual cost will depend upon the number of pounds of wire required, the kind and number of switches, character of cut-out cabinets, etc., and the time required to do the work, so that a close

* Wiring specifications for buildings having their own generating plant should be prepared by an expert.

estimate cannot be made without plans and specifications. Again, wages and prices of material vary to a considerable extent in different parts of the country, so that an estimate that would be about right for one locality would not suffice for another. The following figures,* however, will enable anyone to form an approximate idea of what any proposed wiring-job will cost.

Count cost of labor as not more than one-third the cost of the installation.

For knob-and-tube work in new houses of less than seventeen outlets or twenty-five lamps, with no switches except main switch and a rough cut-out box lined with asbestos, allow $1.50 per outlet.

For same class of work, from 25 to 100 lamps, allow $1.75 to $2.00 per outlet.

The extra labor involved in wiring old buildings will add from 30 to 50% to the above figures.

For each switch-loop with a single-pole snap-switch, add from $1.50 to $1.75.

For each switch-loop with single-pole push-button switch, add from $2.25 to $2.50.

For each lamp controlled by duplex or three-point switches, add from $5 to $6.

For each hardwood cut-out cabinet with door and lock, add from $7 up according to number of circuits and finish.

Iron cut-out cabinets cost from $8.50 up.

Ordinary exposed wiring, as in factories, can usually be run for from $1.00 to $1.75 per drop, including rosettes, cord and sockets, the cost depending very largely upon how closely the drops are spaced.

Small installations with iron-armored conduit will probably cost from $5 to $6 per outlet. Large installations will cost somewhat less.

A private lighting-plant of 200 lamps, wired on the concealed knob-and-tube system, will cost from $1 250 to $1 500, and a similar plant with 600 lamps will cost from $2 500 to $3 000. These prices include engine, dynamo-switchboard, etc., complete, and wiring, but no switches for controlling lamps.

The iron-armored conduit-system will add about $2.75 per outlet.

None of the above estimates include the cost of fixtures except in the case of exposed wiring.

Drop-cord and sockets cost about 90 cts per lamp. Single-lamp fixtures may be purchased from $1.25 upwards; double-lamp fixtures from $2 upwards. Combination-fixtures cost about 25% more than straight electric fixtures.

The price of rubber-covered wire varies from $8 to $60 per 1 000 ft according to size, and of weather-proof wire from 16 cts to 25 cts per pound.

* These are pre-war prices and the data are retained for purposes of comparison of relative values.

Circuit for clock, telephone, bell or other service, run under floor above, concealed. Kind of service wanted ascertained by symbol to which line connects.

ights of center of wall-outlets (unless otherwise specified):

Living-rooms	5 ft 6 in
Chambers	5 ft 0 in
Offices	6 ft 0 in
Corridors	6 ft 3 in
ights of switches (unless otherwise specified)	4 ft 0 in

1.1 gives the candle-power per outlet. Thus (120) means enough tungsten-lamps be placed in this outlet to total 120 watts, three 40-watt lamps, or two 60-watt ps, etc. The candle-power in any case would be 120/1.1 = 110 candle-power.

ARCHITECTURAL ACOUSTICS*

By

WALLACE C. SABINE

LATE PROFESSOR OF PHYSICS, HARVARD UNIVERSITY

Architectural Acoustics a Rational Engineering Problem. Because familiarity with the phenomena of sound has so far outstripped the adequate study of the problems involved, many of them have been popularly shrouded in a wholly unnecessary mystery. Of none, perhaps, is this more true than of ARCHITECTURAL ACOUSTICS. The conditions surrounding the transmission of speech in an enclosed auditorium are complicated, it is true, but are only such as will yield an exact solution in the light of adequate data. It is not unreasonable, therefore, to include problems of architectural acoustics among the RATIONAL ENGINEERING PROBLEMS.

Character and Application of the Problem. The problem of architectural acoustics is necessarily complex, and each room presents many conditions which contribute to the result in a greater or less degree, according to circumstances. To take justly into account these varied conditions, the solution of the problem should be QUANTITATIVE, not merely QUALITATIVE; and to reach its highest usefulness and the dignity of an engineering science it should be such that its application can precede, not merely follow, the construction of the building.

Conditions and Factors of the Problem. In order that hearing may be good in any auditorium it is necessary that the sound should be sufficiently loud, that the simultaneous components of a complex sound should maintain their proper relative intensities, and that the successive sounds in rapidly moving articulation, either of speech or of music, should be clear and distinct, free from each other and from extraneous noises. These three are the necessary, as they are the entirely sufficient, conditions for good hearing. Scientifically the problem involves three factors:

(1) Reverberation.
(2) Interference.
(3) Resonance.

As an engineering problem it involves the shape of the auditorium, its dimensions, and the materials of which it is composed.

Rate of Absorption of Sound. Sound, being energy, once produced in a confined space, will continue until it is either transmitted by the boundary walls or is transformed into some other kind of energy, generally heat. This process of decay is called ABSORPTION. Thus, in the lecture-room of Harvard University, in which, and in behalf of which, this investigation was begun, the RATE

* Adapted and reproduced by permission from a paper read by Dr. W. C. Sabine before the Franklin Institute, Philadelphia, October 30, 1914 and published in the January 1915 issue of the Journal of the Franklin Institute. For information regarding further data, see other papers and treatises on the subject by the author of this article.

OF ABSORPTION was so small that a word spoken in an ordinary tone of voice was audible for five and a half seconds afterwards. During this time even a very deliberate speaker would have uttered the twelve or fifteen succeeding syllables. Thus the successive enunciations blended into a loud sound, through which and above which it was necessary to hear and distinguish the orderly progression of the speech. Across the room this could not be done; even near the speaker it could be done only with an effort wearisome in the extreme if long maintained.

Multiple Reflection, Reverberation and Echoes. With an audience filling the room the conditions were not so bad, but still not tolerable. This may be regarded, if one so chooses, as a process of MULTIPLE REFLECTION from walls, rom ceiling, and from floor, first from one and then another, losing a little at ach reflection until ultimately inaudible. This phenomenon will be called REVERBERATION, including, as a special case, the ECHO. It must be observed, owever, that, in general, reverberation results in a mass of sound filling the whole room and incapable of analysis into its distinct reflections. It is thus more lifficult to recognize and impossible to locate. The term ECHO will be reserved or that particular case in which a short, sharp sound is distinctly repeated by eflection, either once from a single surface, or several times from two or more urfaces.

Rate of Decay of Sound. In the general case of reverberation we are oncerned only with the RATE OF DECAY of the sound. In the special case of he echo we are concerned not merely with its intensity, but with the interval f time elapsing between the initial sound and the moment it reaches the observer. In the room mentioned as the occasion of this investigation no discrete cho was distinctly perceptible, and the case will serve excellently as an illustraion of the more general type of reverberation.

Duration of Audibility of Residual Sound. After preliminary gropings, rst in the literature and then with several optical devices for measuring the itensity of sound, all established methods were abandoned. Instead, the RATE F DECAY was measured by measuring what was inversely proportional to it, he duration of audibility of the reverberation, or, as it will be called here, the URATION OF AUDIBILITY OF THE RESIDUAL SOUND. These experiments may be xplained to advantage here, for they will give more clearly than would abstract iscussion an idea of the nature of reverberation.

Shape of Room and Nature of Furnishings. Broadly considered there re two, and only two, variables in a room, SHAPE (including size), and MATERIALS ncluding furnishings). In designing an auditorium an architect can give condeation to both; in repair-work for bad acoustic conditions it is generally npracticable to change the shape, and only variations in materials and irnishings are allowable. This was, therefore, the line of work in this ise.

The Relative Absorbing Power of Different Substances. It was evident iat, other things being equal, the rate at which the reverberation would disppear was proportional to the rate at which the sound was absorbed. The rst work, therefore, was to determine the RELATIVE ABSORBING POWER of various ibstances. With an organ-pipe as a constant source of sound, and a suitable ironograph for recording, the duration of audibility of a sound after the source id ceased in this room when empty was found to be 5.62 seconds. All the ishions from the seats in Sanders Theater, Boston, Mass., were then brought ver and stored in the lobby. On bringing into the lecture-room a number

of cushions, having a total length of 8.2 meters, the duration of audibility fell to 5.33 seconds. On bringing in cushions of a total length of 17 meters the sound in the room after the organ-pipe ceased was audible for but 4.94 seconds. Evidently the cushions were strong absorbents and rapidly improving the room, at least to the extent of diminishing the reverberation. The result was interesting and the process was continued. Little by little more cushions were brought into the room, and each time the duration of audibility was measured. When all the seats, 436 in number, were covered, the sound was audible for 2.03 seconds. Then the aisles were covered, and then the platform. Still there were more cushions, almost half as many more. These were brought into the room, a few at a time, as before, and draped on a scaffolding that had been erected around the room, the duration of the sound being recorded each time. Finally, when all the cushions from a theater seating nearly 1 500 persons were placed in the room, covering the seats, the aisles, the platform, and the rear wall to the ceiling, the duration of audibility of the residual sound was 1.14 seconds. This experiment, requiring, of course, several nights' work, having been completed, all the cushions were removed and the room was in readiness for the test of other absorbents. It was evident that a STANDARD OF COMPARISON had been established. Curtains of chenille, 1.1 meters wide and 17 meters in total length, were draped in the room. The duration of audibility was then 4.51 seconds. Turning to the data that had just been collected, it appeared that this amount of chenille was equivalent to 30 meters of cushions from Sanders Theater. Oriental rugs (Herez, Demirjik, and Hindoostanee) were tested in a similar manner, as were also cretonne cloth, canvas, and hair-felt. Similar experiments, but in a smaller room, determined the absorbing power of a man and of a woman, always by determining the number of running meters of Sanders Theater cushions that would produce the same effect. This process of comparing two absorbents by actually substituting one for the other is laborious, and it is given here only to show the first steps in the development of a method. Without going into details, it is sufficient here to say that this method was so perfected as to give not merely RELATIVE, but ABSOLUTE, COEFFICIENTS OF ABSORPTION.

Coefficients of Absorption. In this manner a number of COEFFICIENTS OF ABSORPTION were determined for objects and materials which could be brought into and removed from the room, for sounds having a pitch an octave above middle C. In the following table the numerical values are the ABSOLUTE COEFFICIENTS OF ABSORPTION:

Oil-paintings, inclusive of frames	0.28
Carpet-rugs	0.20
Oriental rugs, extra heavy	0.29
Cheese-cloth	0.019
Cretonne cloth	0.15
Shelia curtains	0.23
Hair-felt, 2.5 cm. thick, 8 cm. from wall	0.78
Cork, 2.5 cm. thick, loose on floor	0.16
Linoleum, loose on floor	0.12

When the objects are not extended surfaces, such as carpets or rugs, but essentially spacial units, it is not easy to express the absorption as an absolute coefficient. In the following table the absorption of each object is expressed in terms of a SQUARE METER OF COMPLETE ABSORPTION:

Audience, per person	0.44
Isolated woman	0.54
Isolated man	0.48
Plain, ash settees	0.039
Plain, ash settees, per single seat	0.0077
Plain, ash chairs, bent wood	0.0082
Upholstered settees, hair and leather	1.10
Upholstered settees, per single seat	0.28
Upholstered chairs, similar in style	0.30
Hair-cushions, per seat	0.21
Elastic-felt cushions, per seat	0.20

Coefficient of Absorption of Floors, Ceilings and Wall-Surfaces. Of ven greater importance was the determination of the COEFFICIENT OF ABSORP-ON of floors, ceilings, and all-surfaces. The accom-ishment of this called for a ery considerable extension the method adopted. If e reverberation in a room changed by the addition absorbing material are otted, the resulting curve ll be found to be a portion a hyperbola with dis-aced axes. An example of ch a curve, as obtained in e lecture-room of the Fogg t Museum, Cambridge, ass., is plotted in the agram in Fig. 1. If now e origin of this curve is splaced so that the axes of coordinates are the asymptotes of the rectangular perbola (Fig. 2), the displacement of the origin measures the initial absorbing wer of the room, its floors, walls and ceilings. Such experiments were carried t in a large number of rooms in which the different component materials tered in very different degrees, and an elimination between these different periments gave the following COEFFICIENT OF ABSORPTION for different aterials:

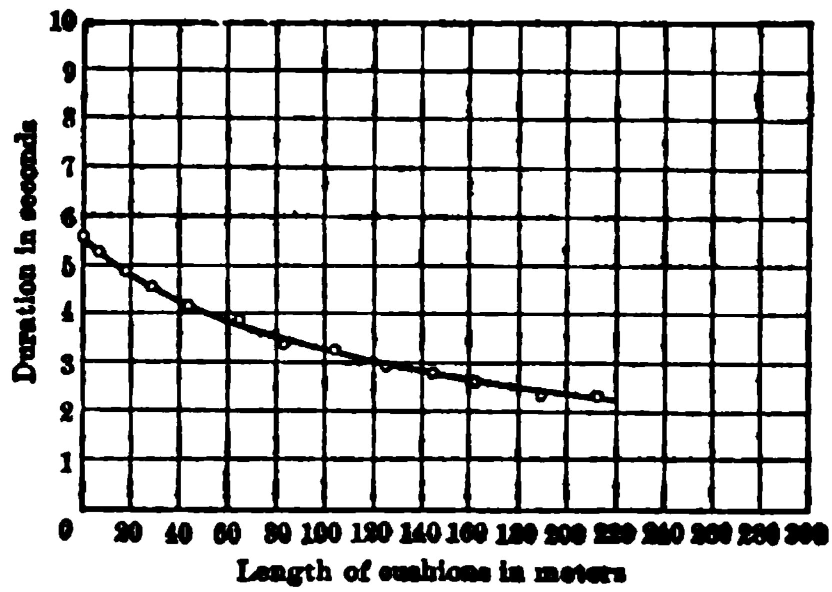

Fig. 1. Curve Showing the Relation of Duration of Residual Sound to Added Absorbing Material

Open window	1.000
Wooden sheathing, hard pine	0.061
Plaster on wooden lath	0.034
Plaster on wire lath	0.033
Glass, single thickness	0.027
Plaster on tile	0.025
Brick set in Portland cement	0.025

Calculating the Reverberation for Any Room. If the experiments in se rooms are plotted in a single diagram, the result is a family of HYPERBOLAS ig. 3) showing a very interesting relationship to the volumes of the rooms. deed, if from these hyperbolas the parameter, which equals the product of the

coordinates, is determined, it will be found to be linearly proportional to the volume of the room. These results are plotted in Fig. 4, showing how strict the proportionality is even over a very great range in volume. We have thus at hand a ready method of calculating the REVERBERATION for any room, its volume and the materials of which it is composed being known. The first five years of the investigation were devoted to violin C, the C an octave above middle C, having a VIBRATION-FREQUENCY of 512 vibrations per second. This pitch was chosen because, in the art of telephony, it was regarded at that time as the characteristic pitch determining the conditions of articulate speech. The planning of Symphony Hall, Boston, Mass., forced an extension of this investigation to notes over the whole range of the musical scale, three octaves below and three octaves above violin-C.

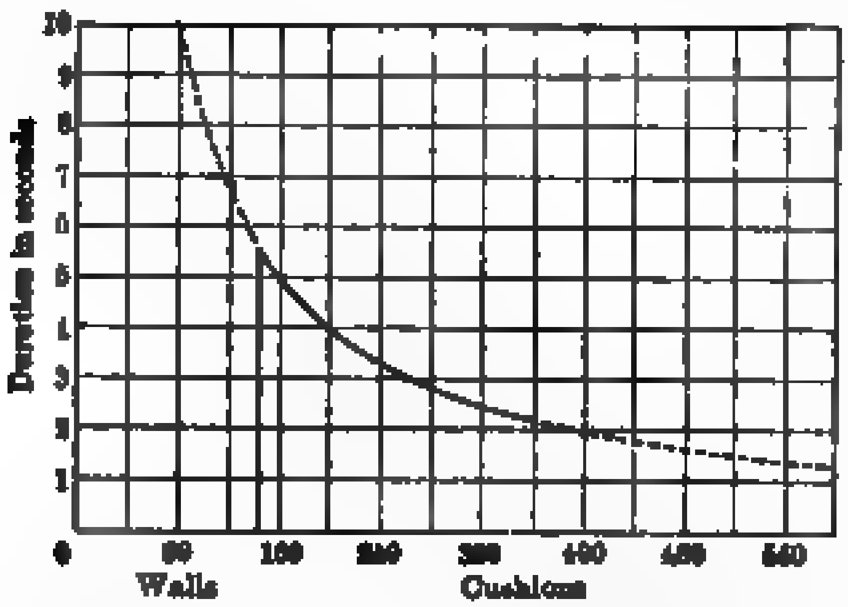

Fig. 2. Curve 5 Plotted as Part of its Corresponding Rectangular Hyperbola. The Solid Part was Determined Experimentally. The Displacement of This to the Right Measures the Absorbing Power of the Walls of the Room

Absorption-Coefficient of an Audience. In the very nature of the problem, the most important datum is the ABSORPTION-COEFFICIENT of an audience, and the determination of this was the first task undertaken. By means of a lecture on one of the recent developments of physics, wireless telegraphy, an audience was thus drawn together and at the end of the lecture requested to remain for the experiment. In this attempt the effort was made to determine the coefficients for the five octaves from $C_2 128$ to $C_6 2048$, including notes E and G in each octave. For several reasons the experiment was not a success. A threatening thunderstorm made the audience a small one, and the sultriness of the atmosphere made open windows necessary; while the attempt to cover so many notes, thirteen in all, prolonged the experiment beyond the endurance of the audience. While this experiment failed, another, the following summer, was more successful. In the year that had elapsed the necessity of carrying the investigation further than the limits intended became evident, and now the experiment was carried from $C_1 64$ to

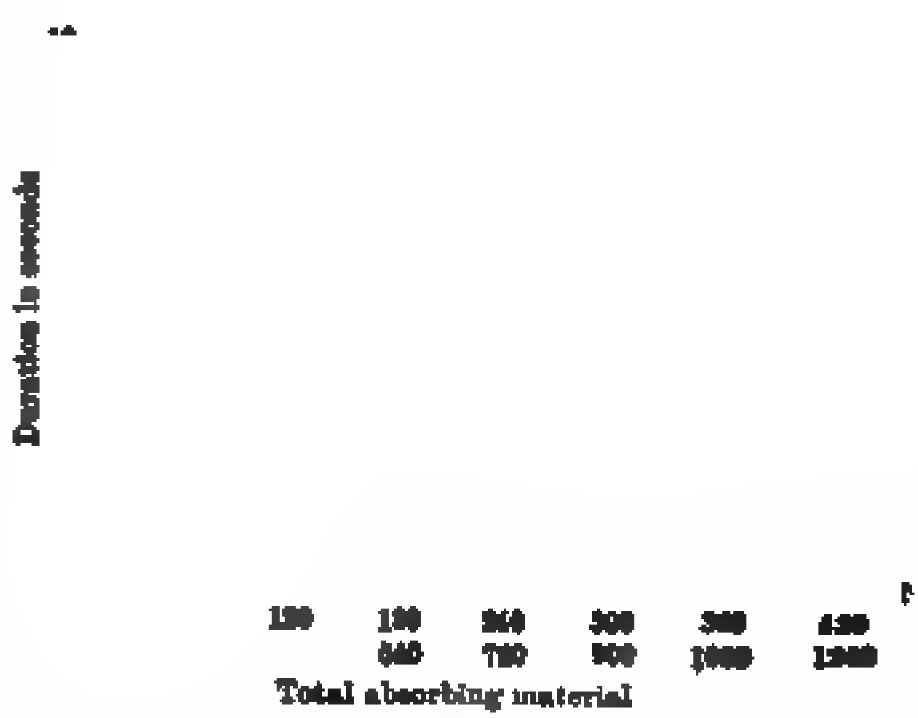

Fig. 3. Curves Entered as Parts of their Corresponding Rectangular Hyperbolas. Three Scales are Employed for the Volumes, by Groups, 1–7, 8–11, and 12

$C_4 4096$, but included only the C notes, seven notes in all. Moreover, bearing in mind the experiences of the previous summer, it was recognized that even seven notes would come dangerously near overtaxing the patience of the audience. Inasmuch as the COEFFICIENT OF ABSORPTION for $C_4 512$ had already been determined six years before, in the investigations mentioned, the coefficient for this note was not redetermined. The experiment was therefore carried out for the lower three and the upper three notes of the seven. The audience, on the night of this experiment, was much larger than that which came the previous summer, the night was a more com-fortable one, and it was

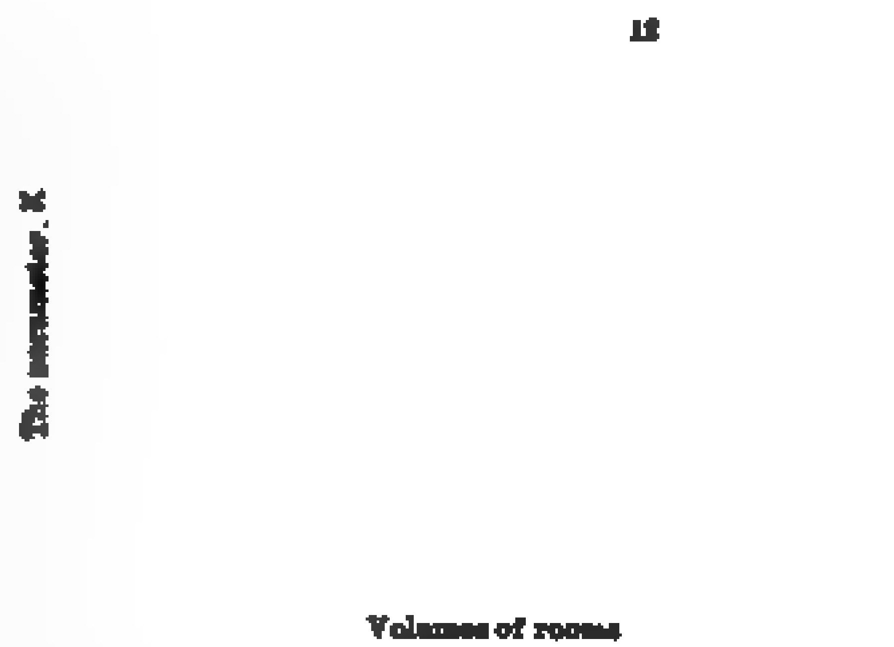

Fig. 4. The Parameters k, Plotted Against the Volumes of the Rooms, Showing the Two Proportional

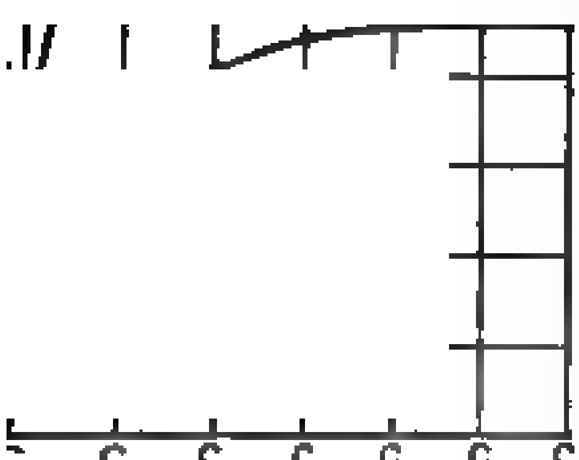
possible to close the windows during the experiment. The conditions were hus fairly satisfactory. In order to get as much data as possible, and in as hort a time, there were nine observers stationed at different points in the room. These observers, whose kindness and skill it is a pleasure to acknowledge, had prepared themselves, by previous practice, for this one experiment. The results of the experiment are shown on the lower curve in Fig 5. This curve gives the COEFFICIENT OF ABSORPTION PER PERSON. It is to be observed that one of the points falls clearly off the smooth curve drawn through the other points. The observations on which this point is based were, however, much disturbed by a street-car passing not far from the building, and the departure of this observation from the curve does not indicate a real departure in the coefficient, nor should it cast much doubt on the rest of the work, in view of the circumstances under which it was secured. Counteracting the, perhaps, bad impression which this point may give, it is considerable satisfaction to note how accurately the point for $C_4 512$, determined six years before by a different set of observers, falls on the smooth curve through the remaining points. The upper curve represents the absorbing power of an audience per square meter, as ordinarily



. 5. Absorbing Power of an Audience for Different Notes

ted. The vertical ordinates are expressed in terms of total absorption a square meter of surface. For the upper curve the ordinates are thus the inary coefficients of absorption. The several notes are at octave-intervals

as follows: $C_1$64, $C_2$128, C_3 (middle C) 256, $C_4$512, $C_5$1024, $C_6$2048, $C_7$4096. In the audience on which these observations were taken there were 77 women and 105 men. The courtesy of the audience in remaining for the experiment and the really remarkable silence which they maintained are gratefully acknowledged.

Absorption of Sound by Wooden Sheathing. The next experiment was on the determination of the ABSORPTION OF SOUND by wooden sheathing. It is not an easy matter to find conditions suitable for this experiment. The room in which the absorption by wooden sheathing was determined in the earlier experiments was not available for these. It was available then only because the building was new and empty. When these more elaborate experiments were under way the room became occupied, and in a manner that did not admit of its being cleared. Quite a little searching in the neighborhood of Boston failed to discover an entirely suitable room. The best one available adjoined a night-lunch room. The night-lunch was bought out for a couple of nights, and the experiment was tried. The work of both nights was much disturbed. The traffic past the building did not stop until nearly two o'clock, and began again at four. The interest of those passing on foot throughout the night, and the necessity of repeated explanations to the police, greatly interfered with the work. This detailed statement of the conditions under which the experiment was tried is made by way of explanation of the irregularity of the observations recorded on the curve, and of the failure to carry this particular line of work further. On the first night seven points were obtained for the seven notes $C_1$64 to $C_7$4096. The reduction of these results on the following day showed variations indicative of maxima and minima, which, to be accurately located, would require the determination of intermediate points. In the experiment on the following night, points were determined for the E and G notes in each octave between $C_2$128 and $C_6$2048. Other points would have been determined, but time did not permit. It is obvious that the intermediate points in the lower and in the higher octave were desirable, but no pipes were to be had on such short notice for this part of the range, and in their absence the data could not be obtained. In the diagram, Fig. 6, the points lying on the vertical lines were determined the first night. The points lying between the vertical lines were determined the second night. The sheathing of the room is of North Carolina pine, 2 centimeters thick. The absorption is here due almost wholly to yielding of the sheathing as a whole. It is not possible now to learn as much in regard to the framing and arrangement of the studding in the particular room tested as is desirable. The accuracy with which these points fall on a smooth curve is, perhaps, all that could be expected in view of the difficulty under which the ob-

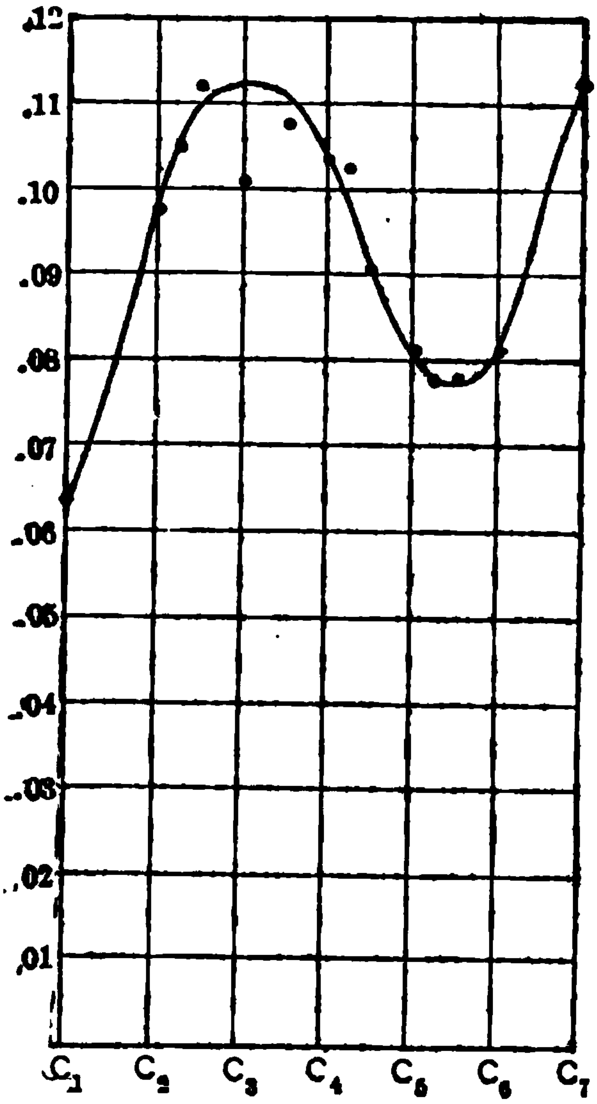


Fig. 6. Absorbing Power of Wooden Sheathing

servations were conducted and the limited time available. One point in particular falls far off from this curve, the point for C_3256, by an amount which is, to say the least, serious, and which can be justified only by the conditions under which the work was done. The general trend of the curve seems, however, established beyond reasonable doubt. It is interesting to note that there is one point of MAXIMUM ABSORPTION, which is due to resonance between the walls and the sound, and that this point of maximum absorption lies in the lower part, though not in the lowest part, of the RANGE OF PITCH tested. It would have been interesting to determine, had the time and facilities permitted, the shape of the curve beyond C_74096, and to see if it rises indefinitely, or shows, as is far more likely, a succession of maxima.

Absorption of Sound by Cushions. The experiment was then directed to the determination of the ABSORPTION OF SOUND by cushions, and for this purpose return was made to the constant-temperature room. Working in the manner indicated in the earlier papers for substances which could be carried in and out of a room, the curves represented in Fig. 7 were obtained. Curve 1 shows the ABSORPTION-COEFFICIENT for the Sanders Theater cushions, with which the whole investigation was begun ten years ago (1904). These cushions were of a particularly open grade of packing, a sort of dry grass or vegetable fiber. They were covered with canvas ticking, and that, in turn, with a very thin, cloth covering. Curve 2 is for cushions borrowed from the Phillips Brooks House. They were of high grade, filled with long, curly hair, and covered with canvas ticking, which was, in turn, covered by a long-nap plush. Curve 3 is for the cushion of Appleton Chapel, hair-covered with a leatherette, and showing a sharper maximum and a more rapid diminution in absorption for the higher frequencies, as would be expected under such conditions. Curve 4

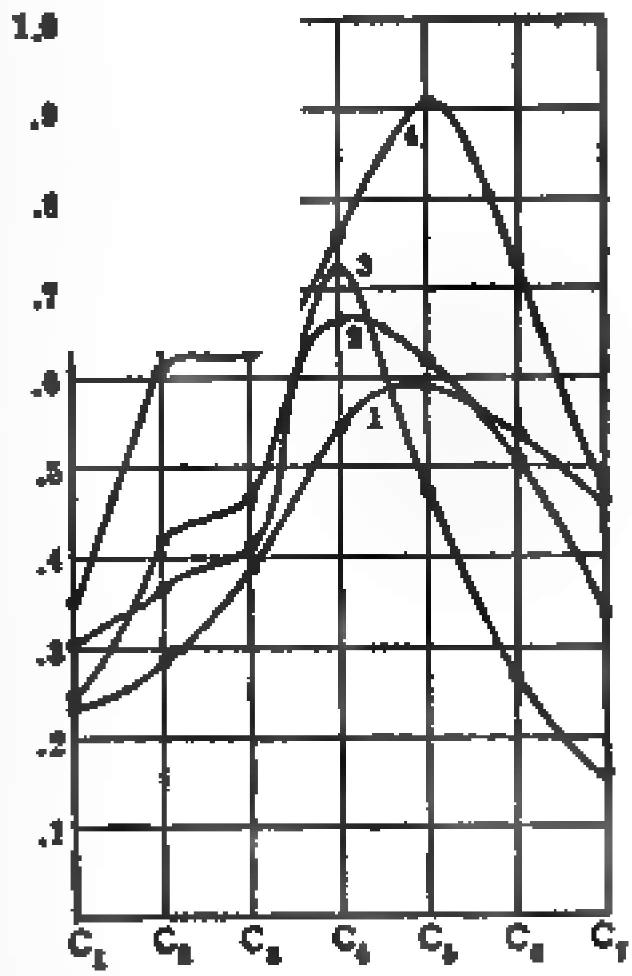

Fig. 7. Absorbing Power of Cushions

is probably the most interesting, because for more standard commercial conditions ordinarily used in churches. This curve is for the elastic-felt cushions of commerce, of elastic cotton covered with ticking and short-nap plush. The absorbing power is per square meter of surface. It is to be observed that all the curves fall off for the higher frequencies, all show a maximum located within an octave, and three of the curves show a curious hump in the second octave. This break in the curve is a genuine phenomenon, as it was tested time after time. It is perhaps due to a SECONDARY RESONANCE, and it is to be observed that it is the more pronounced in those curves that have the sharper resonance in their principal maxima.

Effects of Interference of Sound-Waves. In both articulate speech and music the source of sound is rapidly and, in general, abruptly changing in pitch, quality and loudness. In music one PITCH is held during the length of a note. In articulate speech the unit or ELEMENT OF CONSTANCY is the syllable. Indeed, in speech it is even less than the length of a syllable, for the open-vowel

sound which forms the body of a syllable usually has a consonantal opening and closing. During the constancy of an element, either of music or of speech, a train of sound-waves spreads spherically from the source, just as a train of circular waves spreads outward from a rocking boat on the surface of still water Different portions of this train of spherical waves strike different surfaces of the auditorium and are REFLECTED. After such reflection they begin to cross each other's paths. If their paths are so different in length that one train of waves has entirely passed before the other arrives at a particular point, the only phenomenon at that point is PROLONGATION of the sound. If the space between the two trains of waves is sufficiently great, the effect will be that of an ECHO. If there are a number of such trains of waves thus widely spaced, the effect will be that of MULTIPLE ECHOES. On the other hand, if two trains of waves have traveled so nearly equal paths that they overlap, they will, dependent on the difference in length of the paths which they have traveled, either reinforce or mutually destroy each other. Just as two equal trains of water-waves crossing each other may entirely neutralize each other if the crest of one and the trough of the other arrive together, so two sounds, coming from the same source, in crossing each other may produce silence. This phenomenon is called INTERFERENCE, and is a common phenomenon in all types of wave-motion. Of course, this phenomenon has its complement. If the two trains of water-waves so cross that the crest of one coincides with the crest of the other and trough with trough, the effects will be added together. If the two sound-waves are similarly retarded, the one on the other, their effects will also be added. If the two trains of waves are equal in intensity, the combined intensity will be quadruple that of either of the trains separately, as above explained, or zero, depending on their relative retardation. The effect of this phenomenon is to produce regions in an auditorium of LOUDNESS and regions of comparative or even complete SILENCE. It is a partial explanation of the so-called DEAF REGIONS in an auditorium.

Distribution of Intensity of Sound. It is not difficult to observe this phenomenon directly. It is difficult, however, to measure and record the phenomenon in such a manner as to permit of an accurate chart of the result. Without going into the details of the method employed, the result of these measurements for a room very similar to the Congregational Church in Naugatuck, Conn., is shown in the accompanying chart. The room experimented in was a simple, rectangular room with plain side walls and ends and with a barrel or cylindrical ceiling with the center of curvature at the floor-level. The result is clearly represented in Fig. 8, in which the INTENSITY OF THE SOUND has been indicated by contour-lines in the manner employed in the drawing of the geodetic survey-maps. The phenomenon indicated in these diagrams was not ephemeral, but was constant so long as the source of sound continued, and repeated itself with almost perfect accuracy day after day. Nor was the phenomenon one which could be observed merely instrumentally. To an observer moving about in the room it was quite as striking a phenomenon as the diagram suggests. At the points in the room indicated as HIGH MAXIMA OF INTENSITY in the diagram the sound was so loud as to be disagreeable, at other points so low as to be scarcely audible. It should be added that this distribution of intensity is with the source of sound at the center of the room at the head-level. Had the source of sound been at one end and on the axis of the cylindrical ceiling, the distribution of intensity would still have been bilaterally symmetrical, but not symmetrical about the transverse axis.

Interference-Systems and Reverberation. When a source of sound is maintained constant for a sufficiently long time, a few seconds will ordinarily suffice; the sound becomes steady at every point in the room. The distribution of the

intensity of sound under these conditions is called the INTERFERENCE-SYSTEM, for that particular note, of the room or space in question. If the source of sound is suddenly stopped, it requires some time for the sound in the room to be absorbed. This prolongation of sound after the source has ceased is called REVERBERATION. If the source of sound, instead of being maintained, is short and sharp, it travels as a discrete wave or group of waves about the room, reflected

Fig 8. Distribution of Intensity of Sound

om wall to wall, producing echoes. In the Greek theater there was ordinarily at one echo, "doubling the case-ending," while in the modern auditorium there e many, generally arriving at a less interval of time after the direct sound, and erefore less distinguishable, but stronger and therefore more disturbing.

Photographing Air-Disturbances. The formation and the propagation of HOES may be admirably studied by an adaptation of the so-called SCHLIEREN-

Fig. 9 Photograph of Sound-wave. Vertical Section

Fig. 10. Photograph of Sound-wave. Vertical Section

Fig. 11. Photograph of Sound-wave and Echoes. Vertical Section

Fig. 12. Photograph of Sound-wave and Echoes. Vertical Section

METHODE device for photographing air-disturbances. It is sufficient here to say that the adaptation of this method to the problem in hand consists in the construction of a MODEL in proper scale, of the auditorium to be studied and an inves-

Fig. 13. Photograph of Sound-wave and Echoes. Horizontal Section

tigation of the propagation through it of a proportionally scaled sound-wave. To examine the formation of echoes in a vertical section, the sides of a model are taken off and, as the sound is passing through it, it is illuminated instantaneously

Fig. 14. Photograph of Sound-wave and Echoes. Horizontal Section

by the light from a very fine and somewhat distant electric spark. In the accompanying illustrations, reduced from the photographs, the silhouettes show parts of the shadows cast by the model, and all within are direct photographs of the actual

sound-wave and its echoes. Figs. 9 to 12 show the sound and its echoes at different stages in their propagation through the room, the particular part of the auditorium under investigation being the New Theater in New York City. It

Fig. 15. Photograph of Sound-wave and Echoes. Horizontal Section

is not difficult to identify the MASTER-WAVE and the various ECHOES which it generates, nor, knowing the velocity of sound, to compute the interval at which the echo is heard. To show the generation of echoes and their propagation in

Fig. 16. Photograph of Sound-wave and Echoes. Horizontal Section

a horizontal plane, the ceiling and floor of the model are removed and the photograph taken in a vertical direction. The photographs shown in Figs. 13 to 16 show the echoes produced in the horizontal plane passing through the marble parapet in front of the box.

Solution of Problems Possible in Advance of Construction. While these several factors, REVERBERATION, INTERFERENCE and ECHO, in an auditorium at all complicated are themselves complicated, nevertheless they are capable of an exact solution, or, at least, of a solution as accurate as are the architect's plans in actual construction; and it is entirely possible to calculate in advance of construction whether or not an auditorium will be good, and, if not, to determine the factors contributing to its poor acoustics and a method for its correction.

SPECIFIC GRAVITY

The Specific Gravity of a substance is the number which expresses the ratio that the weight of a given volume of the substance bears to the weight of the same volume of distilled water at a temperature of 62° F.; or, the specific gravity of a body is equal to its weight divided by the weight of an equal volume of water. The specific gravity of a substance, multiplied by the weight of a cubic foot of water, will give the weight of a cubic foot of the given substance. The weight of a cubic foot of water, at 62° F. and at the sea-level, is about 62.355 lb.* The specific gravity of a solid substance may be determined by first weighing a portion of it in air and then in water and dividing the weight in air by the loss of the weight in water; the quotient is the specific gravity required.

Example. A piece of granite weighs 5.32 lb in air; when immersed in water it weighs 3.32 lb.

Solution. Weight in air (5.32 lb) divided by loss of weight in water (2 lb) = 2.66, the specific gravity.

$$2.66 \times 62.355 \text{ lb} = 165.84 \text{ lb} = \text{weight per cubic foot}$$

NOTE. 1 cu ft = 7.48 gal.

* The textbooks differ slightly in regard to this value.

Specific Gravities and Weights per Cubic Foot of Various Substances *

The basis for specific gravities is pure water at 62° F., barometer 30 in. Weight of 1 cu ft of water, 62.355 lb	Average specific gravity. Water = 1	Average weight of 1 cu ft lb

Average of limestones	2.57	160.4
nseed-oil	0.935	58.3

The values given in this table for specific gravities and for weights per cubic foot are AGE values.

The word "dry" in this connection indicates that the wood contains not more than of moisture. Green timbers usually weigh from one-fifth to nearly one-half more dry; ordinary building-timbers, tolerably seasoned, one-sixth more.

Specific Gravities and Weights per Cubic Foot of Various Substances*
(Continued)

The basis for specific gravities is pure water at 62° F., barometer 30 in. Weight of 1 cu ft of water, 62.355 lb	Average specific gravity. Water = 1	Average weight of 1 cu ft lb

WIRE-GAUGES* AND METAL-DATA

A **Wire-Gauge** is a method of designating the diameter of wires or the thick-
ss of sheets of metal by the numbers of a table arranged on a certain fixed basis.
ere are at the present time several gauges, resulting in great confusion,
ble XIII, page 402, gives the diameters of the gauges in common use. The
y legal gauge in this country is the United States standard gauge, described
page 1600. It is used by most of the manufacturers of sheet iron and steel
l tin plate. The Brown & Sharpe gauge is commonly used for designating
: of copper wires (see page 1510); also for sheet copper and brass. Nearly
copper wire, bare and insulated, is ordered, manufactured, and carried in
ck in accordance with this gauge. This might be called the Copper Wire
uge. The American Steel & Wire Company uses the old Washburn &
en and Roebling gauges for all their steel and iron wire and also for wire nails.
: sectional areas for these gauges are given on pages 403 and 1512, taken from
Roebling and American Steel & Wire Company's lists. When placing orders
sheets and wire, it is always best to specify the weight per square or linear
: or the thickness or diameter in thousandths of an inch or in circular mils.
: gauge for steel wire, used by the J. A. Roebling's Sons Company, is given
page 403, and the circular-mil gauge on page 1473. The gauge used by this
ipany is the same as the Washburn & Moen gauge, or the American Steel
Vire gauge, except that the diameters in most cases are given to the nearest
This gauge is so generally used for steel wire that it is sometimes called
Steel Wire Gauge or the Market Wire Gauge. The Birmingham Wire gauge
ie same as Stubs' Iron-Wire gauge, but entirely different from Stubs' Steel-
e gauge. Galvanized telegraph and telephone-wire, both bare and insu-
d, and galvanized armor-wire are usually designated by this gauge. Its
is not very extensive and is becoming less. The new British Standard gauge
he legal standard for Great Britain and is used there for all kinds of wire.
use in this country is very limited. It is known, also, as the English Legal
idard gauge and the Imperial Wire gauge.

* See, also, pages 401, 402, 403, 1469, 1473, 1510, 1512, and 1600.

* For other gauges, see pages 401, 402, 403, 1469, 1473, 1509, 1510 and 1600.

† For iron wire, the values in columns 6 and 7 should be multiplied by 0.98 and [illegible] copper wire, by 1.12.

Kinds of Wire Manufactured by the American Steel and Wire Company

Market-wire, Nos. 0000 to 18.

Annealed stone-wire or weaving-wire, Nos. 16 to 47.

Tinned market-wire, Nos. 0 to 18.

Tinned stone-wire, Nos. 16 to 40.

Gun-screw wire, finished with great care as regards roundness and exactness o gauge, Nos. 18 to 50.

Machinery-wire, Nos. 00000 to 18.

Cast-steel wire, ½-in diameter, down to No. 26.

Drill and needle-steel wire, Nos. 12 to 25.

The term MARKET-WIRE applies to the ordinary and most used forms of Besemer ANNEALED, BRIGHT, GALVANIZED, TINNED and COPPERED wires.

Galvanized-Iron-Wire Strand. The diameter, list-price per 100 ft, weight er 100 feet and approximate breaking-load in pounds for this wire is given in 'able XVI, Chapter XI.

Weights and Areas of Square and Round Bars and Circumferences of Round Steel Bars*

Rules for Estimating the Weight of any Piece of Wrought Iron, Steel or Cast Iron

Wrought Iron.

One cubic foot of wrought iron weighs	480 lb
One square foot, one inch thick, weighs	40 lb
One square inch, one foot long, weighs	3⅓ lb

To find the weight per square foot of sheet iron, multiply the thickness in inches by 40.

To find the weight per linear foot of bars of any section, multiply the cross-sectional area in square inches by 3⅓.

Steel.

One cubic foot of steel weighs (Or just 2% more than wrought iron.)	489.6 lb
One square foot, one inch thick, weighs	40.8 lb
One square inch, one foot long, weighs	3.4 lb

To find the weight per linear foot, of bars of any section, multiply the cross-sectional area in square inches by 3.4; or, if the weight is known, the exact sectional area may be obtained by dividing by 3.4.

Cast Iron.

One cubic foot of cast iron weighs	450 lb
One square foot, one inch thick, weighs	37½ lb
One square inch, one foot long, weighs	3⅛ lb
One cubic inch weighs	0.26 lb

The weight of irregular castings must be estimated by the cubic inch.

Rules for Weights of Castings

Multiply the weight of the pattern by 18 for cast iron, 13 for brass, 19 for lead, 12.2 for tin, 11.4 for zinc; the product is the weight of the casting.

Reduction for Round Cores and Core-Prints

Rule. Multiply the square of the diameter by the length of the core in inches, and the product multiplied by 0.017 is the weight of the pine core to be deducted from the weight of the pattern.

Shrinkage in Castings

Pattern-makers' Rule

Metal	
Cast iron	⅛
Brass	3/16
Lead	⅛
Tin	1/12
Zinc	5/16

of an inch longer per linear foot

* Birkmire.

† a and b = either side, outside measurement. $2a+2b$ = number. Allowance has been made in this table for corners counted twice.

Example. What is the weight per linear foot of a 12 by 16 by 1 in thick column?

Solution. $2a+2b=24+32=56$. Opposite this number, under 1-in-thick metal, we find 162.5, or weight per linear foot of a column 12 by 16 by 1-in-thick.

Note. For flanges, brackets, etc., calculate the cubical contents of same and multiply by 0.26; cast iron averages 450 lb per cu ft.

For larger plates take size of plate ONE-HALF smaller and multiply by 2. Thus a plate 28 by 32 in will weigh twice as much as one 14 by 32 in. For plates more or less than one inch in thickness multiply weight of plate by thickness in inches.

Approximate Weights of Square-Ribbed Cast-Iron Column-Bases

The following table, giving the weight of cast-iron column-bases, will be useful when estimating the steel and iron in tall buildings.*

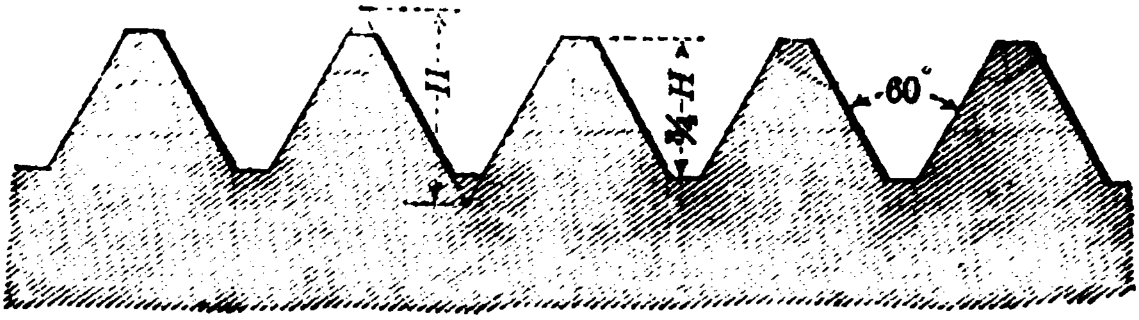
Size of square base, in	Weight, lb	Size of square base, in	Weight, lb
22×22	600	32×32	1 340
24×24	750	34×34	1 450
26×26	880	36×36	1 600
28×28	1 020	38×38	1 720
30×30	1 180	40×40	1 850

* H. G. Tyrrell, in Architects and Builders Magazine, January, 1903.

Screw-Threads, Nuts, and Bolt-Heads

Standard Screw-Threads

Recommended by Franklin Institute, December 15, 1864, and adopted by Navy Department of the United States; by the R. R. Master Mechanics' and Master Car-Builders' Associations; by Jones & Laughlin Steel Company; and by many other of the prominent engineering and mechanical establishments of the country.



Angle of thread 60°. Flat at top and bottom ⅛ of pitch.

Diam of screw, in	Threads per inch	Diam at root of thread, in	Area at root of thread, sq in	Diam of screw, in	Threads per inch	Diam at root of thread, in	Area at root of thread, sq in

Nuts and Bolt-Heads are determined by the following rules, which apply to both square and hexagon nuts:

Short diameter of rough nut = 1½ × diam of bolt + ⅛ in.
Short diameter of finished nut = 1½ × diam of bolt + 1/16 in.
Thickness of rough nut = diam of bolt.
Thickness of finished nut = diam of bolt − 1/16 in.
Short diameter of rough head = 1½ × diam of bolt + ⅛ in.
Short diameter of finished head = 1½ × diam of bolt + 1/16 in.
Thickness of rough head = ½ short diam of head.
Thickness of finished head = diam of bolt − 1/16 in.

The long diameter of a hexagon nut may be determined by multiplying the short diameter by 1.155, and the long diameter of a square nut by multiplying the short diameter by 1.414.

Standard Dimensions of Nuts and Bolt-Heads

NAILS AND SCREWS*

Nails. Based upon the process of manufacture there are three kinds of nails in common use, namely, plate or cut nails, wire nails, and clinch-nails. These are briefly described in the following subdivisions of this article and other data bearing on the subject is included.

(1) **Cut Nails.** Cut nails are made from a strip of rolled iron or steel of the same thickness as the finished nail and a little wider than its length, the fiber of the iron being parallel with the length of the nail. Special machinery cuts the nails out in alternate wedge-shaped slices, the heads are then stamped on them and the finished nails dropped into the casks. Cut nails made from iron are generally preferred for use in exposed positions. Cut nails are made in a variety of shapes to suit special uses. For ordinary use in building, nails of three different shapes are made, and the nails are called COMMON NAILS, FINISH-NAILS and CASING-NAILS. The common nails are used for rough work, finish-nails for finished work, and casing-nails for flooring, matched ceiling and sometimes for pine casings, although the heads are rather too large for finish-work. Cut nails are beginning to return to favor as they have holding power and lasting qualities superior to wire nails.

(2) **Brads.** Brads are thin nails with a small head, used for small finish, panel-moldings, etc. They vary from ¼ to 2 in in length.

(3) **Clout-Nails.** Clout-nails are made with broad, flat heads, and are sold in sizes varying from ⅜ to 2½ in in length. They are used chiefly for fastening gutters and metal-work. Special nails are also made for lathing, slating, shingling, etc.

(4) **Wire Nails.** These have of late years become as common as the cut nails, and are sold at about the same price. They are said to be stronger for driving than the cut nails, not so liable to bend or break, especially when driven into hard woods, and less liable to split the wood; for these reasons they are generally preferred by carpenters. Wire nails are made from wire, of the same section-diameter as the shank of the nail, by a machine which cuts the wire in even lengths, heads and points them, and, when desired, also barbs them. In general the same classification is used for cut nails. It should be noticed that the gauge of the wire and the shape of the head vary in the different kinds, and that some are barbed, others plain. The various types of wire nails are drawn ROUND, SMOOTH or BARBED, for the domestic trade; for export they are drawn OVAL, SQUARE, or DIAMOND-SHAPED, according to the country to which they are to be shipped and its requirements. It is customary to charge 15 cents more per 100 lb for standard nails, BARBED, than for the same nails, SMOOTH.

(5) **Clinch-Nails.** These are made from open-hearth or Bessemer-steel wire. Any ordinary wire nail will clinch, especially when made with DUCK-BILL or flattened points for clinching purposes, or even otherwise, if annealed. These nails are used only in places where it is desired to turn over the ends of the nails to form a clinch, as in the case of battens or cleats.

(6) **Length and Weight of Nails.** The length of nails is designated by PENNIES (*d's*). Two explanations are given for the origin of this classification; for example, that tenpenny nails originally sold for tenpence a hundred, or that 1000 tenpenny nails originally weighed 10 lb. The designation is retained by manufacturers, both for cut and wire nails. The weights expressed in pennies run from two pennies to sixty pennies, the larger sizes being designated by

* Condensed from article by Thomas Nolan in chapter on Builders' Hardware in revised edition of Building Construction and Superintendence, Part II, Carpenters' Work, by F. E. Kidder.

fractions of an inch. The sizes and lengths of various kinds of nails and tacks are given in tables on pages 1531 to 1534.

(7) **Sizes of Nails for Different Classes of Work.** It is imperative for first-class work that nails of proper size should be used and to insure the best results it is well in certain classes of work to specify the sizes which are to be used. For framing, twentypenny, fortypenny and sixtypenny nails, or spikes, are used, according to the size of the timber. For sheathing and roof-boarding, under-floors and cross-bridging, tenpenny common nails should be used. For over-floors tenpenny floor-nails or casing-nails should be used for jointed boards, and ninepenny or tenpenny for matched flooring, although eightpenny nails are sometimes used. Ceiling when ¾ in thick is generally put up with eightpenny casing-nails, and when thinner stuff is used, with sixpenny nails. For inside finish any size of finish-nails or brads from eightpenny down to twopenny is used, according to the thickness and size of the moldings. For pieces exceeding 1 in in thickness, tenpenny nails should be used. Clapboarding is generally put on with sixpenny finish-nails or casing-nails. Threepenny to fourpenny are used for shingling and slating, and threepenny for lathing. For slating, galvanized nails should be used, and they are also better for shingling. Whether wire or cut nails should be used may generally be left to the builder; but in places where there is any danger of the nails being drawn out either by the warping of the boards or from the pull of the nail, cut nails should be used, as they have greater holding power than the wire nails under certain conditions. In regard to the comparative holding power of cut nails and wire nails, and barbed nails and smooth nails, and tests made to determine this property, see page 1531.

(8) **Copper and Brass Nails.** Nails are also made of copper and cast brass, and these are sometimes used in connection with boat-building, refrigerator-work, etc. One wing of the Physical Laboratory Building of Harvard College is put together entirely with brass and copper. As the rooms were intended for use in delicate electrical work, no iron was used in their construction.

(9) **Cement-coated Wire Nails.** The coating consists of various resinous gums mixed by a secret formula, and put on the nails by a baking-process which involves the use of quite complicated machinery. Although the chief market for coated nails is among the users of packages to be shipped, there is a limited market for them among builders, for construction-purposes. The chief merit of the coating is that it gives the nail an adhesive resistance approximately twice that of ordinary wire nails. This quality appeals especially to the manufacturers and users of packages to be shipped, for which strength is particularly wanted. It is desirable for construction-purposes also, but the lack of holding power in plain wire nails is not so apparent in building. About 90% of the output goes to box-factories and large shippers. Cement-coated nails are quite widely used, also, in laying both ordinary and parquetry-flooring. The use of these nails, with a special head which leaves a small hole, gives a firm floor and prevents springing. Though the makers do not claim that the nails are absolutely rust-proof, they do claim that nails thus treated will resist the effects of moisture from 20 to 50% better than the uncoated wire nails. But it is when in use that the non-rusting quality is most evident. There is more coating on the nails than is actually necessary for holding power. The heat caused by the friction of driving the nail softens the coating and the surplus is forced toward the head, completely closing the opening; this prevents the admission of moisture between the wood and the nail. Under similar conditions, the life of a cement-coated nail will be about twice as long as that of an uncoated one. Less force is needed to drive a coated nail as the softened coating forms a lubricant. These nails are made in

wo types, differing only in the heads, and are either COOLERS or SINKERS. he former have large flat heads; the latter, heads slightly reinforced by counter-nking. They are made to replace common nails, in sizes from ¼ in to 1 in, d are used for framing, boarding, shingling and staging, and for boxes and ates. Results of tests made with cement-coated nails to determine their lhesive resistance in comparison with the common smooth-wire nails are given low.

The following table shows the result of tests made at the United States Arsenal, atertown, Mass., in 1902, the wood being pine:

Comparative Adhesive Resistance of Common Smooth-Wire Nails and Cement-Coated Nails

All nails were driven into the same piece and were perpendicular to the grain

Size and name	Diameter, in	Length driven,* in	Adhesive resistance,† lb
enpenny, common, smooth	0.145	2½	167
enpenny, coated	0.117	2½	418
inepenny, common, smooth	0.132	2¼	182
inepenny, coated	0.114	2¼	327
ightpenny, common, smooth	0.132	2	189
ightpenny, coated	0.112	2	316
ixpenny, common, smooth	0.097	1⅝	106
ixpenny, coated	0.092	1⅝	226

* All of the nails were left with their heads projecting from ¼ to ½ in.
† Average of three trials.

Holding Power of Nails. A committee appointed by the Wheeling nail-nufacturers, a number of years ago, to test the comparative holding power of and wire nails, published the following data. The kind of wood is not named. e effect of barbs is slight, and definite conclusions await complete tests.

Pounds Required to Pull Nails Out

	Cut	Wire		Cut	Wire
ventypenny	1 593	703	Sixpenny	383	200
npenny	908	315	Fourpenny	286	123
ghtpenny	597	227			

he holding power of nails varies with the kind of wood into which they are en. Austin T. Byrne gives the relative holding power of woods as ABOUT as ws: White pine, 1; yellow pine, 1.5; white oak, 3; chestnut, 1.6; beech, 3.2; more, 2; elm, 2; basswood, 1.2.

Comparative Holding Power of Cut and Wire Nails

ry thorough tests of the comparative holding power of wire nails and cut OF EQUAL LENGTHS AND WEIGHTS were made at the U. S. Arsenal in 1892 and . From forty series, comprising forty sizes of nails driven in spruce wood, it found that the cut nails showed an average superiority of 60.50%, the com-nails showing an average superiority of 47.51% and the finishing-nails an ge of 72.22%. In eighteen series, comprising six sizes of BOX-NAILS driven pine wood, in three ways the cut nails showed an average superiority of %. In no series of tests did the wire nails hold as much as the cut nails.

Quantity of Nails Required for Different Kinds of Work

For 1 000 shingles* allow 3½ to 6½ lb fourpenny nails or 3½ to 4½ lb threepen
1 000 laths, 7 lb threepenny fine, or for 100 sq yd of lathing, 10 lb threepenny fi
1 000 sq ft of beveled siding, 18 lb sixpenny
1 000 sq ft of sheathing, 20 lb eightpenny or 25 lb tenpenny
1 000 sq ft of flooring, 30 lb eightpenny or 40 lb tenpenny
1 000 sq ft of studding, 15 lb tenpenny and 5 lb twentypenny
1 000 sq ft of 1 by 2½-in furring, 12-in centers, 9 lb eightpenny or 14 lb tenpen
1 000 sq ft of 1 by 2½-in furring, 16-in centers, 7 lb eightpenny or 10 lb tenpen

* Depends upon width and length of shingles and kind of nails.

......	......	....	......	......	....	24	1⅛	666

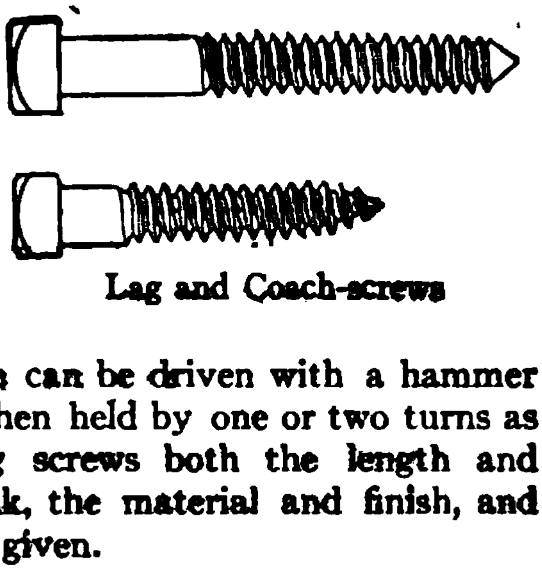
Wire carpet-tacks are made polished, blued, tinned, or coppered; there are also upho[l]sterers' and bill-posters' or railroad tacks.

Expansion-bolt

Expansion-Bolts. These are commonly used for boltin[g] wood or iron to masonry that is already built. A hole i[s] drilled in the masonry of such size that the expansion-nut wi[ll] fit closely, and when the bolt is screwed up the nut expand[s] and binds firmly in the masonry. The illustration shows th[e] Evans expansion-bolt, which is also furnished with screw-hea[d] bolts. There are other forms of expansion-bolts on the marke[t]. From experiments on expansion-bolts it was found that th[e] holding capacity was 264 lb per sq in when embedded in 1: Portland-cement mortar, 843 per sq in when embedded i[n] sulphur and 485 lb per sq in when embedded in lead. Fo[r] average working unit-stresses it is safe to use about one-fifth o[f] the values given. When the work is exposed to rain or moisture sulphur shoul[d]

ot be used as the acid which results will rust the metal and will also tend to lisintegrate the masonwork at the point of entrance of the bolt.

Screws. The substitution of screws for nails in building operations is a narked feature of modern work. Trimming hardware of all descriptions is put n with screws, and a great deal of panel-work, inside finish, etc., is put together vith them. Stop-beads, the casings of plumbing-fixtures, etc., should be fastened with screws, as well as all kinds of store and office-fixtures, and cabinet-work in general, except where the joints are glued. Screws are also largely used n making furniture. They present a neater appearance than nails, have greater olding power and are less apt to injure the material if it should be removed and eplaced. By making holes for the screws with a bit, all danger of splitting the nish is averted. The ordinary type of screw has a gimlet-point by which it can e turned into the wood without the aid of a bit. The heads are made in various rms to suit different uses. Screws are made ordinarily of steel, but sometimes f brass and bronze. The latter sort are used for screwing in place finished hardare of the same material, and have heads finished to correspond with the trimings. Steel screws, also, are finished with blue, bronze, lacquered, galvanized, r tinned surface, to match the cheaper class of trimmings. The galvanized nish is used in building operations at the seashore. Screws with blue surface, alled BLUED SCREWS, are generally used with japanned hardware and for stopads, and wherever a cheap round-headed screw is desired. Silver, nickel, and old-plated screws are also manufactured for use in connection with similar ardware. Steel screws for wood are made in twenty different lengths, varying om ¼ to 6 in, and each length of screw has from six to eighteen varieties in ickness, there being in all thirty-one different gauges; so that altogether there are the market about two hundred and fifty fferent sizes of ordinary screws used for oodwork. The most common shapes are e ordinary flat head, round head and oval ad. The oval-head screw is tapered for untersinking but is slightly rounded on top. tent diamond-point steel screws are made oecially for driving with a hammer. These can be driven with a hammer eir entire length into any hard wood, and then held by one or two turns as curely as the ordinary screw. In ordering screws both the length and mber of the gauge or diameter of the shank, the material and finish, and e use to which they are to be put, should be given.



Lag and Coach-screws

Screws for Metal have the same diameter throughout and the threads are V-aped.

Sizes of Screws. The sizes of screws are given in length in inches and the mber of the gauge, the gauge denoting the diameter. Thus, a 1-in No. 12 screw t in long and 0.2158 in in diameter. The gauge-numbers range from 0 to 30 d the lengths from ¼ to 6 in. The lengths vary by eighths of an inch up to n, by quarters of an inch up to 3 in and by halves of an inch up to 5 in. Screws m ⅝ to 4½ in long are made in about sixteen different gauge-numbers. Table II, page 402, gives the diameter to four places in decimals of an inch of the erican screw-gauge. It should be noticed that, unlike the ordinary wireges, the 0 of the screw-gauge indicates the diameter of the smallest screw ile the diameter of the screw increases with the number of the gauge.

Lag-Screws and Coach-Screws are large, heavy screws used where great ength is required, as in heavy framing, and for fixing ironwork to timber.

Lag-screws with conical point are made with diameters of 5/16, 3/8, 7/16, 1/2, 9/16, 5/8, 3/4, and 1 in, and in lengths from 1 1/2 to 12 in; coach-screws in diameters from 1/4 to 3/4 in and in lengths from 1 1/2 to 12 in. For putting in lag-screws a hole should be bored which has a diameter a little greater than the unthreaded shank of the screw and it should be bored to a depth corresponding to the length of the unthreaded shank. A second hole should then be bored at the bottom of the first hole of a diameter somewhat less than that of the threaded shank and to a depth of about half its length.

Holding Power of Lag-Screws

Tests made by A. J. Cox, University of Iowa, 1891, quoted by Kent, page 324

Kind of wood	Size of screw, in	Size of hole bored, in	Length in wood, in	Maximum resistance, lb	Number of tests
Seasoned white oak	5/8	1/2	4 1/2	8 037	3
Seasoned white oak	9/16	7/16	3	6 480	1
Seasoned white oak	1/2	3/8	4 1/2	8 780	2
Yellow-pine stick	5/8	1/2	4	3 800	2
White cedar, unseasoned	5/8	1/2	4	3 405	2

Hoopes & Townsend give the force required to draw screws out of yellow pine as follows:

Screw	1/2 in	5/8 in	3/4 in	7/8 in	1 in
Wood, depth	3 1/2 in	4 in	4 in	5 in	6 in
Force, pounds	4 960	6 000	7 685	11 500	12 620

Wooden-screws are sold by the gross, lag-screws and coach-screws by the pound.

DATA ON EXCAVATING *

Excavating is almost invariably measured by the cubic yard of 27 cu ft. For measuring excavations of irregular depth see page 65. For computing the contents of wells and cesspools, the circular area in square feet may be obtained from the table on page 51, and this circular area multiplied by the depth in feet will give the contents in cubic feet. The cost of excavating and removing earth is ordinarily made up of the following items:

(1) Loosening the earth for the shovelers;
(2) Loading by shovels into carts or barrows;
(3) Hauling or wheeling it away, including emptying and returning;
(4) Spreading it out on the dump;

For every large job, such as railroad-work, it is also necessary to make an allowance for keeping the hauling-road in repair, for sharpening and repair of tools, and for carts, harness, superintendence and water-carriers. Where the dirt excavated can be spread over the ground immediately surrounding the excavation the loosened dirt may be removed by scrapers without shoveling.

Data for Estimating Cost of Loosening Earth. Two men with a plough and team of horses will loosen from 20 to 30 cu yd of strong, heavy soil per hour or

* All prices given are pre-war prices and are retained for purposes of comparison of relative values.

om 40 to 60 cu yd of ordinary loam. One man with a pick will loosen 1⅛ yd er hour of stiff clay or cemented gravel, 4 yd of common loam, or 6 yd of light and.

The average quantity of LOOSENED EARTH that a man can shovel into a cart er hour is:

Loam or sand	2.0 cu yd
Clay and heavy soils	1.7 cu yd
Rock	1.0 cu yd

Average earth when loosened swells to from 1⅛ to 1¼ times its original bulk n place.

The capacity of vehicles used for moving excavated materials is about as ollows:

Wheelbarrows	3 to 4 cu ft
One-horse dump-carts	18 to 22 cu ft
Two-horse dump-wagons	27 to 45 cu ft *
Drag-scrapers	3 to 7 cu ft
Wheel-scrapers	10 to 17 cu ft
Dump-cars on rails	27 to 80 cu ft

The Economical Length of Haul with drag-scrapers is about 150 ft; with heeled scrapers, 500 ft; with wheelbarrows, 250 ft; with one-horse dump-carts, 0 ft.† The average speed of horses is given as about 200 ft per minute. Much valuable data for estimating ‡ the cost of excavating may be found in e Civil Engineer's Handbooks.

Weight of Earth, Sand and Gravel. For general calculations the following erage values may be taken:

14 cu ft of chalk weigh 1 ton	19 cu ft of gravel weigh 1 ton
18 cu ft of clay weigh 1 ton	22 cu ft of sand weigh 1 ton
21 cu ft of earth weigh 1 ton	

Rock-Excavation. A cubic yard of rock, in place, when broken up by blasting r removal by wheelbarrows or carts, will occupy a space of about 1⅔ cu yd; nsequently the cost of hauling or removal is about 50% more than for dirt.

"With labor at $1 per day, the actual cost for loosening hard rock, including ols, drilling, powder, etc., will average about 45 cents per cubic yard, in place, der all ordinary circumstances. In practice it will generally range between 30 d 60 cents, depending on the position of the strata, hardness, toughness, water d other considerations. Soft shales and other allied rocks may frequently be osened by pick and plough as low as 15 to 20 cents, while on the other hand shalw cuttings of very tough rock with an unfavorable position of strata, especially the bottoms of excavations, may cost $1 per cu yd, or even considerably more. e quarrying of average hard rock requires about ¼ to ½ lb of powder per cu yd, place, but the nature of the rock, the position of the strata, etc., may increase to ½ lb or more. Soft rock frequently requires more powder than hard. A od churn-driller will drill 8 to 10 ft in depth of holes about 2½ ft deep and 2 in ameter per day in average hard rock, at from 12 to 18 cents per ft." §

* The ordinary load for two-horse wagons such as are commonly used for hauling dirt, nd and gravel is from 1¼ to 1½ cu yd.

† Inspectors' Pocket-Book, by A. T. Byrne.

‡ See, also, Handbook of Cost Data, by H. P. Gillette.

§ The Civil Engineer's Pocket-Book, J. C. Trautwine.

DATA ON STONEWORK *

Kinds of Stonework. The commonest kind of stonework, that is, for walls is called RUBBLEWORK. No work whatever is done on the stones except to break them up with a hammer. If the wall is built in courses it is designated COURSED RUBBLE. When the stones showing on the outside face of the wall are squared, the work is designated ASHLAR. Ashlar is of two kinds: COURSED ASHLAR, in which the stones are laid to form courses around the building, all of the stones in any course being of the same height, and BROKEN ASHLAR, in which stones of different heights are used. HAMMER-DRESSED ASHLAR designates work where the stones are roughly squared with a hammer. This is a very cheap class of work. Good ashlar work should be squared on the bench with chisels, and with beds and end-joints cut square to the face. Stonework which requires a chisel or any other tool except a hammer for dressing is called CUT WORK. Cut work costs considerably more than hammer-dressed work.

Measurement of Stonework. Rough stone from the quarry is usually sold under two classifications: rubble-stone and dimension-stone. Rubble includes the pieces of irregular size most easily obtained from the quarry, and suitable for cutting into ashlar 12 in or less in height and about 2 ft long. Stone ordered to be of a certain size, to SQUARE over 24 in each way and to be of a particular thickness, is called DIMENSION-STONE. The price of the latter varies from two to four times the price of RUBBLE. Rubble is generally sold by the ton or car load. Footings and flagging are usually sold by the square foot; dimension stone by the cubic foot. In Boston, granite blocks for foundations are usually sold by the ton.

In Estimating on the Cost of Stonework put into a building, the custom varies with different localities, and even among contractors in the same city. Dimension-stone footings, that is, squared stones 2 ft or more in width, are usually measured by the square foot. If built of large rubble or irregular stones the footings are measured in with the wall, allowance being made for the projection of the footings. Rubblework is almost universally measured by the PERCH of 16½ cu ft. The author has been unable to find any locality where the legal perch of 24¾ cu ft is used by stone-masons. In Philadelphia, St. Louis and some sections of Illinois, 22 cu ft are called a perch. Railroad-work is usually measured by the cubic yard. When stonework is let by the perch, the number of cubic feet to the perch should be stated in the contract, and it should be stated also, whether or not openings are to be deducted. As a rule no deductions are made for openings of less than 70 superficial feet.

Data for Estimating Cost.† The price of common rubble as it comes from the quarry will vary from 55 cts to $1.65 per ton, free on board cars at point of delivery, according to the cost of quarrying, transportation, etc. $1.35 a perch is probably a fair average.

A ton of most of the different kinds of stones will make from 1 perch to 1½ perches.

The cost of laying one perch of stone may be estimated by the following items:

Labor: mason 2⅝ hrs, helper 1¾ hrs, based on two helpers to three masons; sand ⅛ load; lime ¾ bu, or if laid in all-cement mortar, one perch will require from ⅓ to ½ bbl of cement.

At average wages, rubble cellar-walls, from 18 in to 2 ft thick, laid in lime mortar

* The prices given are pre-war prices.

† For wages different from those named, the average costs may be calculated by proportion.

tar, vary in cost from \$2.75 to \$4.50 per perch, \$3.50 a perch being a fair average; in all-cement mortar, from \$3.50 to \$4.50 per perch.

The cost of ashlar depends very largely upon the kind of stone used and the distance it has to be brought. The price of the rough stock on the cars at the point of delivery may vary from 75 cts to \$1.35 per cu ft for granite and from 60 cts to \$1.10 for sandstones and limestones, depending largely upon cost of transportation. 1 cu ft of stone should make 2 sq ft of ashlar, at least. Some quarries get out stone especially suitable for ashlar and sell it at about 30 cts per lin ft for courses 12 in high.

The cost of cutting ashlar, with stone-cutters' wages at \$4 per day, will average about 15 cts per sq ft for soft stones, from 15 to 20 cts per sq ft for hard sandstones and limestones, and from 25 to 30 cts for granite. The cost of setting ashlar will vary from 10 cts per sq ft to 25 cts for soft stones or 30 cts for granite, 15 cts being an average price for sandstones and limestones.

The cost of cut-stone trimmings depends so largely upon the kind of stone that it is quite impossible to give prices that would be of very much service. The following figures, however, may serve as a general guide in forming a rough estimate, the prices if anything being probably a little above the cost of the local stone in most localities.

Flagstones for Sidewalks, ordinary stock, natural surface, 3 in thick, with joints pitched to line, in lengths, along walk, from 3 to 5 ft, will cost, for a 3-ft walk, about 10 cts per sq ft, or if 2 in thick, 7 cts; for a 4-ft walk, 10 cts; and for a 5-ft walk, 12 cts per sq ft. The cost of laying all sizes will average about 4 cts per sq ft. The above figures do not include the cost of hauling.

Curbing. 4 by 24-in granite will cost at the quarry from 30 to 35 cts per lin ft; digging and setting will cost from 12 to 14 cts additional; and the cost of freight and hauling must also be added.

Cut Bluestone. The following figures show the approximate cost of cut bluestone for various uses:

Flagstone, 5 in, size 8 by 10 ft, edges and top bush-hammered, per square foot face-measure	\$0.75
Flagstone, 4 in, size 5 by 5 ft, select stock, edges clean-cut, natural top, per square foot	0.45
Door-sills, 8 by 12 in, clean-cut, per linear foot	1.35
Window-sills, 5 by 12 in, clean-cut, per linear foot	0.80
Window-sills, 4 by 8 in, clean-cut, per linear foot	0.45
Window-sills, 5 by 8 in, clean-cut, per linear foot	0.60
Lintels, 4 by 10 in, clean-cut, per linear foot	0.65
Lintels, 8 by 12 in, clean-cut, per linear foot	1.25
Water-table, 8 by 12 in, clean-cut, per linear foot	1.25
Coping, 4 by 21 in, clean-cut, per linear foot	1.20
Coping, 4 by 21 in, rock-face edges and top, per linear foot	0.50
Coping, 3 by 15 in, rock-face edges and top, per linear foot	0.35
Coping, 3 by 18 in, rock-face edges and top, per linear foot	0.40
Steps, sawed stock, 7 by 14 in, per linear foot	1.10
Platform, 6 in thick, per square foot	0.50

To the prices of cut stone above given must be added the cost of setting, which, for water-tables, steps, etc., will be about 10 cts per linear foot, and for window-sills, etc., about 5 cts per linear foot. For fitting, about 10 cts per cu ft, and for trimming the joints after the pieces are set in place, about 5 cts per cu ft should also be added.

DATA ON BRICKS AND BRICKWORK

Clay Bricks. The word brick as commonly used refers to the materi clay, molded into the required shape and size and burned in a kiln; an until quite recently, practically all bricks were made from clay. At th present time, however, bricks are also made from sand and lime, and fro cement and concrete. Clay bricks may be broadly classified as commo bricks, face-bricks, fire-bricks and paving-bricks. As to the process of man facture, bricks are classified as soft-mud bricks, stiff-mud bricks, dry-press bricks and repressed bricks.

Soft-Mud Bricks are made by tempering clay with water until it becomes so and plastic and then pressing it into molds either by hand or by a machine Practically all handmade bricks are soft-mud bricks. Soft-mud bricks are ofte REPRESSED to make face-bricks.

Stiff-Mud Bricks are machine-made. The clay is first ground, and onl enough water is added to make a stiff mud. The stiff clay is forced through a di or dies in the machine in a continuous stream, which is cut up automatically int pieces the size either of the end or side of the brick. If the opening is the size o the end of the brick, the bricks are END-CUT BRICKS; if of the size of the side of th brick, they are SIDE-CUT BRICKS. Stiff-mud bricks can readily be distinguishe from soft-mud bricks by their appearance. As good if not better bricks can b made by the soft-mud process as by the stiff-mud process, and in the Easter States the soft-mud bricks are probably the stronger. As far as the author' observation has extended in the Western States, the stiff-mud bricks are as a rul preferable to those made by the soft-mud process. Stiff-mud bricks are usuall heavier than soft-mud bricks or hand-made bricks.

Dry-pressed Bricks are made almost entirely for face-work, although in some localities dry-pressed bricks are also used as common bricks. Hydraulic-pressed bricks are dry-pressed.

Molded Bricks are always dry-pressed. Very fine bricks are made by thi process.

Burning of Bricks. Bricks made by any of the above processes require to be burned in a kiln. According to their position in the kiln, common bricks ar designated ARCH-BRICKS or hard-burned bricks, RED BRICKS or well-burned bricks, and SALMON BRICKS or soft bricks. As a rule, salmon bricks are not fit to use in an exterior or bearing-wall.

Color of Bricks. The color of bricks depends principally upon the presenc of iron, lime, or magnesia in the clay. A large proportion of oxide of iron give a clear bright red. Magnesia produces a brown color, and when in the presence of iron, a light-drab color. Dry-pressed bricks are often colored artificially either by mixing clays of different composition, or by mixing mineral colors with the finely ground clay.

Fire-Bricks are ordinarily made from a mixture of flint clay and plastic clay. They are usually white, or white mixed with brown, in color and are used for th lining of furnaces, fireplaces and tall chimneys.

Paving-Bricks are very hard bricks, usually vitrified or annealed. They ar much more expensive than common bricks and are seldom used in the con struction of buildings.

Size and Weight of Clay Bricks. In this country there is no legal standard fo the SIZE OF BRICKS, and the dimensions vary with the maker and also with th

locality. Common standard sizes are 8 by 3¾ by 2¼ in. and 8 by 3⅝ by 2¼ in. In the New England States the common brick averages about 7¾ by 3¾ by 2¼ in. In most of the Western States common bricks measure about 8¼ by 4⅛ by 2⅜ in, and the thicknesses of the walls measure about 9, 13, 18 and 22 in for thicknesses of 1, 1½, 2 and 2½ bricks. The sizes of all common bricks vary considerably in each lot, according to the degree to which they are burned; the hard bricks being from ⅛ to 3/16 in smaller than the salmon bricks. In England the common standard is 8¾ by 4⅜ by 2¾ in. Pressed bricks or face-bricks are more uniform in size, as most of the manufacturers use the same size of mold. The prevailing sizes for pressed bricks are 8⅜ by 4⅛ by 2⅜ and 8⅜ by 4 by 2¼ in. Pressed bricks are also made 1½ in thick and 12 by 4 by 1½ in, those of the latter size being generally termed ROMAN BRICKS or TILES.

The WEIGHT OF BRICKS varies considerably with the quality of the clay from which they are made, and also, of course, with their size. Common bricks average about 4½ lb each, and pressed bricks vary from 5 to 5½ lb each. For the STRENGTH OF BRICKS and brickwork, see Chapter V. The FIRE-BRICKS are made in various forms to suit the required work. A straight brick measures 9 by 4½ by 2½ in and weighs about 7 lb. To secure the best results fire-bricks should be laid in the same clay from which they are manufactured, this being mixed with water into a thin paste. The thinner the joint, the better the wall will stand heat. For PAVING-BRICKS the size and weight vary according to the locality and to the requirements of the specifications. Former STANDARDS were, 2½ by 4 by 8 in, required 61 bricks to the square yard, on edge, and weighed 7 lb each. REPRESSED bricks, 2½ by 4 by 8½ in, require 58 to the square yard and weigh 6½ lb each. METROPOLITAN bricks were 3 by 4 by 9 in, required 45 to the square yard, and weighed 9½ lb each.*

Lime-Mortar Bricks.† General Description. The so-called SAND-LIME BRICKS were originally made of lime mortar, molded in brick form and hardened by exposure to the air. Such bricks are said to have been largely used in ancient times, and it is claimed that remains of such materials are now in evidence and in a good state of preservation. It is known that they were formerly used in Europe in localities where other materials were not readily available, and that they have been used in some localities in this country during the past thirty-five years. The writer knows of several houses in Haddonfield, N. J., built of such bricks, generally with the exterior surfaces plastered. One of them, however, said to be about twenty-five years old, has not been plastered, and an inspection (1915) shows the bricks to be in an excellent state of preservation. Lime-mortar bricks harden by the absorption of carbonic-acid gas from the air. This gas enters into combination with the lime, forming carbonate of lime. The hardening process requires several weeks' exposure under cover and the product has not virtues sufficient to commend it where other materials are available.

Sand-Lime Bricks. It was discovered in Germany about 1875 that lime-mortar bricks could be hardened in a few hours under heat and pressure, and it was found later that the chemical reaction under the new process differs essentially from that just described, and that the percentage of lime can be greatly reduced. The fundamental principles of sand-lime-brick manufacture are now common property and only the details of the manufacture are patentable. Sand-lime bricks were first made in Germany about 1880, and the more extended commercial development of the industry dates back in Europe to about 1888,

* Building Inspectors' Pocket-book, A. T. Byrne.

† Condensed from article on Sand-Lime Bricks by Professor Thomas Nolan in the revised edition of Building Construction and Superintendence. Part I, Masons' Work, by F. E. Kidder.

and in this country, to about 1900. There are now (1915) several factories in operation in this country.

Manufacture of Sand-Lime Bricks. Pure silica sand, mixed with from 5 to 10% of high-calcium lime and a certain proportion of water, is molded under very high pressure into the form of bricks. These are piled loosely on cars holding about 1000 bricks each and placed in a steel cylinder large enough to hold from 10 to 20 cars. The cylinder is then closed and steam is turned in and maintained at a pressure of from 120 to 135 lb to the square inch for from 8 to 10 hours, when the cylinder is opened and the bricks removed, ready for use. The tremendous pressure, which is said to be 100 tons on each brick, under which the bricks are formed, causes great density and a bringing of the component elements into close contact. The heat in the cylinder dries the bricks and causes a chemical reaction between the lime and a portion of the silica, forming a hydrosilicate of lime, an insoluble and durable element, which bonds the remaining particles of the sand together and forms a comparatively strong cementing material. The small residue of uncombined lime combines, in the course of time, either with silica or with carbonic-acid gas from the air, until no free lime remains. The bricks thus become harder and stronger with age. In regard to the constitution of sand-lime bricks, Edwin C. Eckel says:* "It may be safely assumed that a sand-lime brick as marketed consists of (1) sand-grains held together by a network of (2) hydrous lime silicate, with probably (if a magnesian lime is used) some allied magnesium silicate, and (3) lime hydrate or a mixture of lime and magnesia hydrates. These three elements will always be present, and the structural value of the brick will depend in large part on the relative percentage in which the sand and the hydrates occur."

Quality of Sand-Lime Bricks. The quality of the product depends mainly upon the selection and treatment of the sand and the lime. Pure silica sands, containing a large percentage of fine grains passing through screens of from 80 to 150 mesh, are preferable. Clay or kaolin are dangerous elements and should not be present in quantities of more than 5%. The lime should be, preferably, high-calcium lime, the magnesium silicates formed by impure limes not being as strong as calcium silicates. Some manufacturers use ready-hydrated lime, others hydrate the lime themselves, before mixing it with the sand, and others grind the quicklime, mix it with the sand and slake it in the sand. The other most important element affecting quality is the press. After pressing and before steaming, the bricks are very fragile and the press should be such that they are subjected to no shaking or friction after the pressure is removed from the mold. Vertical clay-brick presses have been commonly used, but do not appear to be well adapted to the purpose. The rotary table-presses seem to be most successful.

Tests of Sand-Lime Bricks. If the sand is reasonably clean and pure, and the lime finely divided, and if the bricks are sound and have a good metallic ring, they will stand weather-exposure well. If a brick stands in still water for an hour and the moisture rises more than 1/2 in, it is not a first-class brick; if the moisture rises 2 in, its use for facings is questionable; and if the moisture rises 3 in, it should not be used on outside work of any importance. Authentic tests† have been made for crushing, fire-resistance, frost-resistance, acid-resistance and absorption, from which it may be concluded that under proper conditions

* "The Production of Lime and Sand-lime Brick in 1906," in the Government Report dated 1907 and published in 1908, on The Mineral Resources of the United States for the Calendar Year, 1906.

† See, also, Tests Upon Sand-Lime Bricks, made by Ira H. Woolson, November, 190[illegible] at the Testing Laboratory, Columbia University, New York, for The National Association of Manufacturers of Sand-Lime Products.

manufacture sand-lime bricks are produced having the following physical characteristics: Crushing strength, average, between 2 500 and 3 000 lb per sq in, although some specimens have shown over 5 000 lb per sq in; modulus of rupture, average, about 450 lb per sq in; fire-resistance, but little inferior to that of fire-brick; frost-resistance, generally good; acid-resistance, superior; absorption, from 7 to 10% in 48 hours; rate of absorption, slower than for clay bricks; average absorption for complete saturation, 14%; reduction of compressive strength by saturation for absorption-test, average 33%.

Special Properties of Sand-Lime Bricks. The bricks are square, straight, uniform in size and homogeneous in composition and density. They cleave accurately under the stroke of the trowel and present a weather-surface with the good qualities of stone. They can be cut, carved or sand-blasted, are easily washed clean and show no efflorescence. These claims are well established for properly manufactured sand-lime bricks. It should be further stated that common bricks and facings are made in the same press, the only difference being in the selection of the materials and in the handling of the raw bricks. It is therefore claimed that a rational and homogeneous exterior wall-structure is possible, since backings and facings may be built and bonded in even courses, with Flemish or other ornamental bonds. Some factories, however, manufactured, at first, inferior bricks and care should still be taken in selections from their outputs. Frequently the ordinary runs of sand-lime bricks are not as strong as the average clay building bricks and some of them are too low in their resistance to frost.

Colors of Sand-Lime Bricks. The natural color is pearl-gray, varying in warmth with the composition of the sand. Permanent colors are produced by introducing mineral oxides with the raw materials in quantities varying according to the intensity of color desired; but as the oxides are foreign materials in the bricks, they affect the quality of the latter in proportion to the quantity used.

Glazed and Enameled Bricks. The term GLAZED BRICKS and ENAMELED BRICKS as commonly used, refer practically to the same product, and neither includes what is known as SALT-GLAZED BRICK. The enameled or glazed bricks are generally dipped or sprayed and then burned, whereas the salt-glaze is obtained by the introduction of salt into the fire-boxes of kilns while the bricks are being burned. Glazed or enameled bricks are generally divided into two classes: (1) true enameled bricks, which have a glaze containing the coloring matter applied to it without any intermediate SLIP; (2) bricks which have a transparent glaze placed over a white or colored slip, the slip coming between the glaze and the material to be glazed. The latter is the process most used in this country. Manufacturers differ as to which process produces the best bricks although it would seem as though the true enamel would not chip or peel as readily. These bricks can be made in a variety of colors, from white to dark green or chocolate, and either in a HIGHLY GLAZED FINISH or in a DULL, SATIN-FINISH, the latter finish being quite desirable in many instances on account of its doing away with the glare of the more highly glazed bricks or tiles. An enameled surface may be distinguished from a glazed surface by chipping off a piece of the brick. The glazed brick will show a layer of slip between the glaze and the body of the brick; while the enameled brick will show no line of demarcation between the body of the brick and the enamel. American enameled and glazed bricks are now extensively used for the exterior surfaces of buildings, particularly for street-fronts and light-courts, and for interior side walls and partitions of rooms or buildings used for a great variety of purposes.

Sizes of Enameled Bricks. Enameled bricks are made in two regular sizes: (1) English size, 9 by 3-in enameled surface, 4½-in bed, and (2) American size, 8⅜ by 2¼-in enameled surface, 4⅛-in bed. The English-size bricks cost about $10 per 1 000 more than the American, but on account of the saving in the number of bricks, labor of laying and mortar in joints, the former really effect a saving of about 7 cts per sq ft. Enameled bricks are made, also, with a 12 by 4½-in enameled surface, 2¼-in bed.

Cost of Enameled Bricks.* The selling price of enameled bricks varies from $75 per 1 000 for the American size to $85 for the English size and $100 for the 12 by 4½ by 2¼-in size; and at these prices the cost of the bricks per square foot is:

	cts
American size, 7 bricks to the foot	52½
English size, 5⅓ bricks to the foot	45⅓
English flat, 3⅗ bricks to the foot	36
12 by 4½ by 2¼-in, 3 bricks to the foot	30

Colors of Enameled Bricks. The standard colors carried in stock are white, cream and buff; other colors are made to order.

Estimating Quantities and Cost of Brickwork *

Methods of Calculation. The almost universal method of calculating the cost of brickwork is by estimating the number of thousands of bricks, WALL MEASURE, and then multiplying by a certain price per thousand, which is usually determined by experience and which is intended to include every item affecting the cost, and very often the profit. All of the common brickwork in any given building is usually figured at the same price per thousand bricks, the adjustment for the more expensive portions of the work being made in the manner of measuring. The principle underlying this system is explained as follows:

"The plain dead wall of brickwork is taken as the standard, and the more difficult, complicated, ornamental, or hazardous kinds of work are measured up to it so as to make the compensation equal. To illustrate, if, in one day, a man can lay 2 000 bricks in a plain dead wall, and can lay only 500 in a pier, arch, or chimney-top in the same time, the cost of labor per thousand in such work is four times as much as in the dead wall, and he is entitled to extra compensation; but instead of varying the price, the custom is to vary the measurement to compensate for the difference in the time, and thus endeavor to secure a uniform price per thousand for all descriptions of ordinary brickwork, instead of a different price for the execution of the various kinds of work." †

Measurements of Brick-Quantities. PLAIN WALLS are quite universally figured at 15 bricks to the square foot of an 8 or 9-in wall, 22½ bricks per square foot of a 12 or 13-in wall, 30 bricks per square foot of a 16 or 17-in wall, and 7½ bricks for each additional 4 or 4½ in in the thickness of the wall. These figures are used without regard to the size of the bricks, the effect of the latter being taken into account in fixing the price per thousand. No deduction is made for OPENINGS of less than 80 sup ft, and when deductions are made for larger openings the width is measured 2 ft less than the actual width. HOLLOW WALLS are all measured as if solid. To the number of bricks thus obtained is added

* The prices given are pre-war prices.

† From Rules of Measurement adopted by the Brick Contractors' Exchange of Denver, Col.

measurement for piers, chimneys, arches, etc. FOOTINGS are generally measured in with the wall by adding the width of the projection to the height of the wall. Thus if the footings project 6 in on each side of the wall, 1 ft is added to the actual height of the wall. CHIMNEY-BREASTS and PILASTERS are measured by multiplying the girth of each breast or pilaster from the intersections with the wall by the height, and then by the number of bricks corresponding with the thickness of the projection. FLUES in chimneys are always measured solid. Detached CHIMNEYS and CHIMNEY-TOPS are measured as a wall having a length equal to the sum of the side and two ends of the chimney, and a thickness equal to the width of the chimney. Thus a chimney measuring 3 ft by 1 ft 4 in would be measured as a 16 or 17-in wall, 5 ft 8 in long. The rule for INDEPENDENT PIERS is to multiply the height of each pier by the distance around it in feet, and consider the product as the superficial area of a wall whose thickness is equal to the width of the pier. In practice, many masons measure only one side and one end of a pier or chimney. ARCHES of common bricks over openings of less than 80 sup ft are usually disregarded in estimating. If the arch is over an opening larger than 80 sq ft, the height of the wall is measured from the springing-line of the arch. No deduction is made in the wall-measurement for stone sills, caps, or belt-courses, nor for stone ashlar, if the same is set by the brick-mason. If the ashlar is set by the stone-mason, the thickness of the ashlar is deducted from the thickness of the wall. The sum of all of these measurements represents a certain number of THOUSANDS OF BRICKS, and the whole is then multiplied by a common price per thousand, as \$6, \$8, \$12, or \$16, according to whatever the cost of plain brickwork may be. If the building is to be faced with PRESSED BRICKS, the actual cost of the pressed bricks, as nearly as it can be computed, is added to the estimated price of the common brickwork, nothing being added for laying the pressed bricks, nor anything deducted from the common-brick measurement, the measurement of the common work displaced by the pressed bricks being assumed to offset the difference in the cost of laying the pressed and common brickwork. In arriving at the COST OF THE PRESSED BRICKS, the external superficial area of the walls faced with such bricks is computed, and all openings, belt-courses, stone caps, etc., are deducted. Five-in stone sills are not usually deducted. If a portion of the wall is covered by a porch, so that common bricks may be used back of it, this space, also, is deducted. The net pressed-brick surface is then multiplied by 6, 6½, or 7 to obtain the number of bricks required, 6½ giving about the number of pressed bricks of the standard size required to the square foot. The TOPPING OUT of chimneys, if of face-brick, is measured by girting the chimneys, multiplying by the heights, and adding the sums to the wall-area.

Example. As a simple example of this system of estimating consider a small brick house, 28 by 32 ft in plan, without cross-walls, the basement-walls being in thick, with footings 2 ft 6 in wide; the first-story walls, 13 in thick; the second-story walls, 9 in thick; the height of the basement-walls from the trench to the top of the first-story joists, 8 ft 6 in; the height of the walls from the first-story joists to the top of the second-story joists, 10 ft 6 in; and from the second-story joists to the plate, 9 ft.

WALL-MEASUREMENTS. Basement-walls: 120 ft (girth of building) by 9 ft in (height and projection of footing) by 22½ bricks per square foot; equal to 550 bricks.

First-story walls: 120 ft by 10 ft 6 in by 22½ bricks per square foot; equal 28 360 bricks.

Second-story walls: 120 ft by 9 ft by 15 bricks per square foot; equal to 200 bricks.

Topping out two chimneys, each 1 ft 9 in by 1 ft 5 in by 14 ft high above roof:

2 by 14 ft by (1 ft 5 in plus 1 ft 9 in plus 1 ft 5 in) by 30 bricks per square foot; equal to 3 850 bricks.

Total brickwork: 74 960 bricks. At $9 per 1 000, the cost is $674.64.

PRESSED BRICKS. From the grade to the under side of the plates, the wall measures 22 ft 6 in and it is to be faced with pressed bricks of the standard size, costing $15 per 1 000. The door-openings and window-openings measure 384 sup ft.

The surface of pressed bricks equals 120 by 22½ ft, equal to.....	2 700 sq ft
The deduction for openings is..............................	384 sq ft
Area, after deduction..................................	2 316 sq ft
Addition for two chimneys, 2 by 14 by 6 ft 4 in, equal to.......	177 sq ft
Total	2 493 sq ft

2 493 by 6½ equals 16 204 pressed bricks, which, at $15 per 1 000 cost, equals $243.

The total amount of the bid is $674.64 plus $243, or $917.64.

The above figures are supposed to include the necessary lime, sand, water, scaffolding, etc., required to make the mortar and put up the walls, and also a profit for the contractor; but anything in the way of ironwork, such as ties, thimbles, ash-doors, etc., are figured as additions to this amount.

Detailed Estimates of Brickwork. In estimating by the above method, the price per thousand is to some extent a matter of guesswork, and while an experienced contractor may perhaps make as accurate an estimate by this method as is possible by any, yet it is often necessary to estimate the work in detail; and even when the work has been estimated as above, it is necessary for the contractor to know how many bricks and how much sand and lime will be required to do the work. The following data will assist in making such detailed estimates.

With the size of bricks used in the Western States, from 16½ to 17⅔ common bricks are required to the cubic foot after deducting openings, and figuring the thickness of walls at 8, 12, 16, 20 in, etc., the actual number of bricks required will run about two-thirds of the WALL-MEASURE when the openings are of about the average number and size.

The number of pressed bricks will be about 6 or 6½ bricks to the foot, after deducting openings.

To lay 1 000 common bricks, kiln-count, requires 2½ bushels or 200 lb of white lime and ⅝ cu yd of sand. For a good lime-and-cement mortar, allow 2 bushels of lime, 1 bbl of cement and ⅝ cu yd of sand. For 1 : 3 cement-and-sand mortar, allow 1½ bbl of cement and ⅝ cu yd of sand, or one-half a load.

To lay 1 000 pressed bricks with buttered joints will require 2 bushels of lime (160 lb) and ¼ cu yd of sand; with spread joints, from 2 to 2½ bushels of lime and from ⅜ to ½ cu yd of sand.

If colored mortar is used, about $1 per 1 000 bricks should be added for the mortar-color.

A brick-mason, working on a city job under a good foreman, will lay, on an average, 60 pressed (face) bricks per hour, and from 150 to 175 common bricks per hour, 160 being a fair average. In country towns the average is nearer [illegible] per hour.

With wages at 62½ cts per hour for masons, 31¼ cts for hod-carriers, and 3[illegible] cts for mortar-mixers and carriers, sand at 60 cts per cu yd, and lime at 40 cts per bushel of 80 lb, brick-masons in Denver state that the average cost of laying common bricks in 12-in walls is about $6 per 1 000, kiln-count, and of laying pressed bricks about $10 per 1 000.

For common brickwork, one helper will be required for every mason, and on 9-in walls, faced with pressed bricks, one helper to every two masons. In building common-brick fireplaces and chimneys one mason and helper will lay about 600 bricks in a day of nine hours.

As a rule, chimneys built of common bricks and with 4-in walls cost about 50 cts per running foot, in height, for single flues, and 90 cts for double flues.

Space Required for Piling Bricks. One thousand bricks closely stacked occupy about 56 cu ft of space. One thousand old bricks, cleaned and loosely stacked, occupy about 72 cu ft.

A brick-layer's hod measures 21 by 7 by 7 in, and will hold 18 bricks.

A mortar-hod measures 24 by 12 by 12, and 12 in across the top.

Mortar-Colors are usually in the form of dry powders, or of pulp or paste. The powders are put up in barrels, the number of pounds to the barrel and price per pound being about as follows:

Red, in 500-lb barrels, dry	from 1¾ to 2 cts per lb
Brown, in 450-lb barrels, dry	from 1¾ to 2½ cts per lb
Buff, in 400-lb barrels, dry	from 1¾ to 2½ cts per lb
Black, in 1 000-lb barrels, dry	from 3 to 3½ cts per lb

For lots of less than full barrels an extra charge is sometimes made for packing and drayage.

In pulp or paste-form:

Red, brown and buff	1¾ cts per lb
Black	3 cts per lb
All other colors	2 cts per lb

Colors in paste-form can be obtained in casks, barrels, half-barrels and kegs, all (except black and buff) weighing, in casks, 900 lb; in barrels, 550 lb; and in half-barrels, 375 lb. The buff weighs, in casks, 700 lb; in barrels, 450 lb; and in half-barrels, 300 lb. Black weighs, in barrels, 450 lb; and in half-barrels, 275 lb. To color the mortar for laying 1 000 bricks with ⅛-in joints requires about 50 lb of red, terra-cotta color, amber, fern-green and salmon; 40 lb for buff, brown, colonial drab or French gray; and 25 lb for black. For wider joints, a larger quantity of stain must be used. For paste-colors an average mixture is, 1 bucket of paste-color to 7 buckets of mortar for brickwork with ⅛-in joints. When the colors are in the form of dry powder they are first mixed with dry sand, the cold slaked lime is then added and again mixed thoroughly. It is very important that the color be uniformly mixed. If it is not added at first, but left until the mortar is made, the labor of mixing is doubled. The more thorough the mixing the less color is required. Mortar colors should never be mixed with hot lime. When the color is in the form of a pulp or paste, it should be thoroughly hoed in, in order to secure a uniform and smooth shade. For very fine pressed bricks, the stained mortar should be strained through a coarse sieve.

Efflorescence on Brickwork. A white EFFLORESCENCE often appears on brickwork, especially in moist climates and damp places. It may spread over large areas of the wall-surface although originating in the mortar joints. Soluble salts, principally of soda, potash and magnesia, in the cement or lime mortar, are dissolved by the water absorbed by the mortar and later precipitated on the surface of the brickwork as a white deposit, when the water evaporates. This deposit seems to be greater with the natural than with the Portland-cement mortars and still heavier with lime mortar. The origin of the efflorescence may be in the bricks themselves as well as in the mortar used. This is the case when the bricks are made from clays containing iron pyrites or burned with sulphurous

coal. Moisture in such bricks tends to dissolve the sulphate of magnesia and sulphate of lime, which, in the evaporation of the water, are deposited on the surface as crystals of these salts. Efflorescence may result, also, from water impregnated from the mortar, absorbed by the bricks and then evaporated, leaving the whitish deposits; and it is sometimes caused by adulterations in certain MORTAR-COLORS. As a PREVENTIVE, General Gilmore recommended the addition to every 300 lb of the cement powder, 100 lb of quicklime, and from 8 to 12 lb of any cheap ANIMAL FAT, which is to be thoroughly incorporated with the quicklime before the latter is slaked, preparatory to adding it to the cement. The alkaline salts tend to be SAPONIFIED by the fat. This is not an entirely satisfactory treatment, and as a rule it only partly prevents or removes the objectionable deposits; and this addition to the cement retards its setting and somewhat diminishes its strength. It is claimed by some that boiled LINSEED-OIL, applied to brickwork in two coats, will lessen the absorption of moisture for from one to three years and thus lessen the tendency to efflorescence. It is usually mixed in the proportion of 2 gal of oil to 300 lb of dry cement, either with or without lime; but it is injured by the mortar and, like the fat, retards the setting of the cement mortar and weakens it. In order to diminish the chances of efflorescence on brickwork, the walls should be made as IMPERVIOUS as possible by laying the bricks in a rich well-mixed Portland-cement mortar and filling all joints full and solid. If the building is on damp ground, carefully constructed DAMP-PROOF COURSES of the proper materials should be built into the walls or a course of horizontal joints near the bottom of the walls should be WATERPROOFED. Reasonably hard bricks should be used for facing, projections and exposed top surfaces waterproofed and provided with drips, and the roof, cornice and gutters made water-tight. When efflorescence is due to the penetration of rain-water or moisture into the brickwork and it is required to preserve the texture and color of the work, the surface may be coated with preparations of PARAFFINE or with various patented WATERPROOFING MIXTURES. The preparations containing paraffine are usually applied hot, and the walls, also, are heated by portable heaters previous to the application. They give fairly good results, but are quite expensive, owing to the time and labor required for their application. Brick walls may be rendered impervious to moisture by washes applied by the SYLVESTER PROCESS. These washes consist of an ALUM-SOLUTION made by dissolving 1 lb of alum per gallon of water, and a SOAP-SOLUTION made by dissolving 2½ lb of pure hard soap per gallon of water. The brick walls should be dry and clean and it is recommended that they should not be colder than 50° F. The soap-wash is made boiling hot and then applied to the brickwork. The temperature of the alum-solution is usually from 60° to 70° F. when put on. One wash is applied and allowed to dry for about 24 hours, after which the other wash is put over it. When ALUMINIUM SULPHATE, improperly called ALUM, is substituted for the alum, the cost of the wash is less, only two-thirds as much sulphate as alum is required and the results are better.

LIME *

Nature and Properties of Lime. Chemically, lime is calcium oxide. Used in a broader sense, it is the class-name of a great variety of products manufactured by the calcination of LIMESTONE. Limestone consists of the carbonates of calcium and magnesium which vary widely in their ratio to each other. The limestones used in the manufacture of lime products may be divided into two

* Valuable practical data relating to lime and plaster has been furnished by the Charles Warner Company, of Wilmington, Del.

classes, CALCIUM LIMESTONES and DOLOMITIC LIMESTONES. High-calcium limestones contain only a relatively low percentage of magnesium carbonate, while dolomitic limestones contain a considerable amount of it. Dolomitic limestone usually corresponds roughly to the theoretical formula of dolomite ($CaCO_3$) ($MgCO_3$). The CALCINATION of limestone consists of heating to expel the carbon dioxide. The product resulting from calcination of limestone is known as QUICKLIME and possesses great affinity for water. SLAKING is the process of adding water to quicklime. During the process of slaking, heat is energetically evolved and much of the water driven off in the form of steam. During this slaking process, also, high-calcium quicklimes must be agitated and stirred continually or a portion will fail to receive the proper quantity of water and will contain unslaked particles which are likely to slake after being used in the work, causing POPPING, PITTING and disintegration. Dolomitic limes do not slake so energetically, and while they should be stirred while slaking, this is not so necessary as with high-calcium limes. Either class of quicklime, through faulty manufacture, is likely to contain over-burned portions which slake with difficulty and may cause popping, etc., if the lime-paste is not carefully screened before use. The SETTING and HARDENING of common lime mortar is due, first, to the drying out and, secondly, to the absorption of carbon dioxide from the atmosphere and the formation of crystals of calcium carbonate to which the strength of the mortar is ascribed. In the manufacture and use of common lime mortar, therefore, the raw material, limestone, is first calcined, and the carbon dioxide expelled; it is then slaked with water and forms calcium hydroxide, in which the water is gradually replaced by carbon dioxide. The lime thus eventually returns to its original carbonate form. As far as the ultimate result is concerned, there is generally little difference between high-calcium and dolomitic quicklimes. Owing to greater familiarity with one or the other of the classes of lime, architects and builders in certain sections of the country prefer one to the other.

Specifications for Quicklime. The lime industry has in recent years been made the subject of careful study and the following clauses give the various requirements of Standard Specifications for Quicklime adopted by the American Society for Testing Materials in 1915.

1. DEFINITION. Quicklime is a material the major part of which is calcium oxide or calcium and magnesium oxides, which will slake on the addition of water.

2. GRADES. Quicklime is divided into two grades:

(*a*) Selected. Shall be well-burned, picked free from ashes, core, clinker or other foreign material.

(*b*) Run-of-Kiln. Shall be well-burned, without selection.

3. FORMS. Quicklime is shipped in two forms:

(*a*) Lump. Shall be kiln-size.

(*b*) Pulverized Lime. Lump lime reduced in size to pass a ¼-in screen.

4. CLASSES. Quicklime is divided into four classes: (*a*) High-Calcium; (*b*) Calcium; (*c*) Magnesian; (*d*) High-Magnesian.

5. BASIS OF PURCHASE. The particular grade, form and class of quicklime desired shall be specified in advance by the purchaser.

I. Chemical Properties and Tests

(A) Sampling

6. LIME IN BULK. When quicklime is shipped in bulk, the sample shall be so taken that it will represent an average of all parts of the shipment from top to bottom, and shall not contain a disproportionate share of the top and bottom layers, which are most subject to changes. The samples shall comprise at least shovelfuls taken from different parts of the shipment. The total sample

taken shall weigh at least 100 lb and shall be crushed to pass a 1-in ring and quartered to provide a 15-lb sample for the laboratory.

7. LIME IN BARRELS. When quicklime is shipped in barrels, at least 3% of the number of barrels shall be sampled. They shall be taken from various parts of the shipment, dumped, mixed and sampled as specified in Section 6.

8. LABORATORY SAMPLES. All samples to be sent to the laboratory shall be immediately transferred to an air-tight container in which the unused portion shall be stored till the quicklime is finally accepted or rejected by purchaser.

(B) Chemical Tests

9. CHEMICAL PROPERTIES. (*a*) The classes and chemical properties of quicklime shall be determined by standard methods of chemical analysis. (*b*) Samples shall be taken as specified in Sections 6, 7 and 8. (*c*) Quicklime shall conform to the following requirements as to chemical composition:

CHEMICAL COMPOSITION

Properties considered	High-Calcium		Calcium		Magnesian		High-Magnesian	
	Selected	Run of kiln	Selected	Run of kiln	Selected	Run of kiln	Selected	Run of kiln
Calcium oxide, per cent..	90 (min)	90 (min)	85–90	85–90	..	..	..	..
Magnesium oxide, per ct.	..	..	..	..	10–25	10–25	25 (min)	25 (min)
Calcium oxide plus magnesium oxide, min, per cent................	90	85	90	85	90	85	90	85
Carbon dioxide, max, per cent................	3	5	3	5	3	5	3	5
Silica plus alumina plus oxide of iron, max, per cent...............	5	7.5	5	7.5	5	7.5	5	7.5

II. Physical Properties and Tests

10. PERCENTAGE OF WASTE. An average 5-lb sample shall be put into a box and slaked by an experienced operator with sufficient water to produce the maximum quantity of lime putty, care being taken to avoid burning or drowning the lime. It shall be allowed to stand for 24 hours and then washed through a 20-mesh sieve by a stream of water having a moderate pressure. No material shall be rubbed through the screens. Not over 3% of the weight of the selected quicklime nor over 5% of the weight of the run-of-kiln quicklime shall be retained on the sieve. The sample of lump lime taken for this test shall be broken so that all of it will pass a 1-in screen and be retained on a ¼-in screen. Pulverized lime shall be tested as received.

III. Inspection and Rejection

11. INSPECTION. (*a*) All quicklime shall be subject to inspection.

(*b*) The quicklime may be inspected either at the place of manufacture or the point of delivery, as arranged at time of purchase.

(*c*) The inspector representing the purchaser shall have free entry, at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer's works which concern the manufacture of the quicklime ordered. The manufacturer shall afford the inspector all reasonable facilities for inspection and sampling, which shall be so conducted as not to interfere unnecessarily with the operation of the works.

(*d*) The purchaser may make the tests to govern the acceptance or rejection of the quicklime in his own laboratory or elsewhere. Such tests, however, shall be made at the expense of the purchaser.

12. REJECTION. Unless otherwise specified, any rejection based on failure to pass tests prescribed in accordance with these specifications shall be reported within five days from the taking of samples.

13. REHEARING. Samples which represent rejected quicklime, shall be preserved in air-tight containers for five days from the date of the test-report. In case of dissatisfaction with the results of the tests, the manufacturer may make claim for a rehearing within that time.

Hydrated Lime. The slaking of quicklime is an operation which is almost invariably carried on by laborers who have little or no conception of the importance of their task. As a result, many failures have been charged to lime in the past which actually were due to improper preparation during the slaking operation. The new product known as HYDRATED LIME has been offered widely to the trade in recent years and has met with much success. Hydrated lime is a dry flocculent powder resulting from the slaking of quicklime by mechanical means, with an amount of water which is sufficient to satisfy the calcium oxide, but insufficient to make a paste or putty. Hydrated lime is manufactured in mechanical hydrators in which the batches of quicklime and water used are carefully proportioned by weight. After passing from the hydrator, hydrated lime is subjected to a mechanical system of separation which eliminates the coarse or impure particles which may cause popping, etc. Hydrated lime is sold in bags of definite weight and requires only to be mixed with sand and water to make the mortar. The bags have usually been made of heavy burlap or duck cloth, containing 100 lb, or of paper, containing 40 lb. Several of the more prominent manufacturers of hydrated lime in the United States employ chemists who regularly superintend the manufacture of hydrated lime, just as the chemists in Portland-cement factories superintend the proportioning of the raw mix going to the kilns to be burned for Portland cement. The hydrated lime manufactured under such chemical supervision is a reliable product free from tendencies which might give rise to popping, pitting or disintegration. Hydrated lime of good quality may be used for almost any purpose for which lime mortar is used, and is by some considered a more reliable product than quicklime. Among the newer uses for hydrated lime may be mentioned its employment in cement mortars and concrete. An addition of about 15% of hydrated lime to cement mortar or concrete decreases its permeability to water, reduces the cracking due to shrinkage, etc., and increases the plasticity of the mortar or concrete, thus preventing separation of the sand, stone and cement and causing the mixture to flow and fill the forms more readily. (See Macgregor tests, page 276.)

Specifications for Hydrated Lime. The following clauses give the various requirements of Standard Specifications for Hydrated Lime adopted by the American Society for Testing Materials in 1915.

1. DEFINITION. Hydrated lime is a dry flocculent powder resulting from the hydration of quicklime.

2. CLASSES. Hydrated lime is commercially divided into four classes: (*a*) High-Calcium; (*b*) Calcium; (*c*) Magnesian; (*d*) High-Magnesian.

3. BASIS OF PURCHASE. The particular type of hydrated lime desired shall be specified in advance of purchase.

I. Chemical Properties and Tests

4. SAMPLING. The sample shall be a fair average of the shipment. Three per cent of the packages shall be sampled. The sample shall be taken from the surface to the center of the package. A 2-lb sample to be sent to the laboratory

shall immediately be transferred to an air-tight container, in which the unused portion shall be stored until the hydrated lime has been finally accepted or rejected by the purchaser.

5. Chemical Properties. (*a*) The classes and chemical properties of hydrated lime shall be determined by standard methods of chemical analysis. (*b*) The non-volatile portion of hydrated lime shall conform to the following requirements as to chemical composition:

Chemical Composition

Properties considered	High-Calcium	Calcium	Magnesian	High-Magnesian
Calcium oxide, per cent.....	90 (min)	85–90	....	....
Magnesium oxide, per cent..	....	....	10–25	25 (min)
Silica plus alumina plus oxide of iron, max, per cent	5	5	5	5
Carbon dioxide, max, per cent	5	5	5	5
Water....................	Sufficient to hydrate the calcium-oxide content	Sufficient to hydrate the calcium-oxide content	Sufficient to hydrate the calcium-oxide content	Sufficient to hydrate the calcium-oxide content

II. Physical Properties and Tests

6. Fineness. A 100-g. sample shall leave by weight a residue of not over 5% on a standard 100-mesh sieve and not over 0.5% on a standard 30-mesh sieve.

7. Constancy of Volume. Hydrated lime shall be tested to determine its constancy of volume in the following manner: Equal parts of hydrated lime under test and volume-constant Portland cement shall be thoroughly mixed together and gauged with water to a paste. Only sufficient water shall be used to make the mixture workable. From this paste a pat about 3 in in diameter and ½ in thick at the center, tapering to a thin edge, shall be made on a clean glass plate about 4 in square. This pat shall be allowed to harden 24 hours in moist air and shall be without popping, checking, cracking, warping or disintegration after 5 hours' exposure to steam above boiling water in a loosely closed vessel.

III. Packing and Marking

8. Packing. Hydrated lime shall be packed either in cloth or paper bags and the weight shall be plainly marked on each package.

9. Marking. The name of the manufacturer shall be legibly marked or tagged on each package.

IV. Inspection and Rejection

10. Inspection. (*a*) All hydrated lime shall be subject to inspection.

(*b*) The hydrated lime may be inspected either at the place of manufacture or the point of delivery, as arranged at the time of purchase.

(*c*) The inspector representing the purchaser shall have free entry, at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer's works which concern the manufacture of the hydrated lime ordered. The manufacturer shall afford the inspector all reasonable facilities for inspection and sampling, which shall be so conducted as not to interfere unnecessarily with the operation of the works.

(*d*) The purchaser may make the tests to govern the acceptance or rejection of the hydrated lime in his own laboratory or elsewhere. Such tests, however, shall be made at the expense of the purchaser.

11. Rejection. Unless otherwise specified, any rejection based on failure to pass tests prescribed in these specifications shall be reported within five working days from the taking of samples.

12. Rehearing. Samples which represent rejected hydrated lime shall be preserved in air-tight containers for five days from the date of the test-report. In case of dissatisfaction with the results of the tests, the manufacturer may make claim for a rehearing within that time.

Alca Lime. A recent development in the lime industry is Alca Lime.* This is a material said to combine the plasticity and sand-carrying qualities of lime mortar with the strength, hardness and quicker set of the gypsum plasters. It is composed of approximately 85% of hydrated lime and 15% of a specially prepared material containing alumina and silica in such proportions as to combine, forming bodies which greatly contribute to the strength, hardness and plasticity of the product. It is sold in 100-lb packages and requires only to be mixed with sand and water before use. When used for plastering, it has the characteristics of lime mortar, and while it becomes hard and strong, it is claimed that it is free from the so-called sounding-board effects noticed in some hard-wall plasters. It is not injured by water and is often used for outside stucco-work and also as a brick-laying mortar in place of lime mortar gauged with Portland cement. The manufacturers' directions for the use of Alca Lime should be carefully observed, and this may be said of all prepared plastering or cementing materials.

Useful Data on Quicklime. Quicklime is shipped either in barrels or in bulk. In dry climates it will keep for a long time in bulk, but in damp climates and along the coast it soon slakes unless enclosed in barrels. By Act of Congress, August 23, 1916, it is required that lime in barrels shall be packed only in barrels containing 280 lb or 180 lb, net weight. When shipped in bulk it is generally sold by the bushel of 80 lb, 3½ bushels or 280 lb, net, of lime being considered as equivalent to a large barrel. Other weights are 180 lb, net, per small barrel, and 64 lb per cu ft. The average yield of LIME-PASTE from the best Eastern limes has been found to be 2.62 times the bulk of unslaked lime. A barrel of good quality well-burned lime should make 8 cu ft, or 20 pails, of lime-paste or putty. Careful experiments conducted by United States engineers have demonstrated that the best mortar is obtained by mixing one part of lime paste to two parts of sand.

Cements. For data on cements, see Chapter III.

SAND AND GRAVEL

Sand is obtained from banks or pits, from river-beds and from the seashore. Pit-sand or bank-sand, free from clay or earthy materials, is generally considered the best for mortar, although excellent sand is often obtained from river-beds. Sea-sand contains alkaline salts which attract and retain moisture and which, unless thoroughly washed, cause efflorescence when used in brickwork. Both sea-sand and river-sand have more or less rounded grains, to which lime or cement will not adhere as well as to sharp, angular grains. Both are extensively used, however, for lack of better materials. The use of sand in mortar is to prevent excessive shrinkage and to save the cost of lime or cement. Sand, when used in the proportion of 1 : 2, strengthens lime mortar, but any addition of sand to cement weakens it.

Screening Sand. Sand for mortar must ordinarily be screened. Sand for brown mortar for plastering or common brickwork is ordinarily run through a

* This is a patented article and is offered for sale by many licensees in the United States under the Spackman patents.

No. 4 screen having 4 by 4 meshes to the inch. For sand finish and mortar pressed brickwork, either a No. 10 or a No. 12 screen with 10 by 10 or 12 by meshes to the inch is commonly used. For rubble stonework the sand is ordinarily screened, unless it contains much gravel, in which case it should screened through a ⅜-in mesh.

Weight of Sand. Dry sand weighs from 80 to 115 lb per cu ft. The average weight of damp (not wet) sand is about 96 lb per cu ft, or about 2 600 per cu yd. The voids for ordinary sand range from 0.3 to 0.5 of the volume, the average for screened sand suitable for mortar being 0.35 of the volume. The more uneven the grains in size the smaller the percentage of the voids. A one-horse load of sand contains about 22 cu ft. Two-horse loads vary from 1¼ to 2 yd. The amount hauled per load in the larger cities is generally fixed by the Team Owners' Association. 1¼ yd is a fair load, 1½ yd a good load and 2 yd a large load.

LATHING AND PLASTERING

Wooden Laths should be well seasoned, free from sap, bark and dead knots. Bark on laths is quite sure to stain the plaster. White pine is generally considered the best wood for laths, although spruce and hemlock laths are much used. Hard pine is not a good material, as it contains too much pitch. The regular size of laths is ¼ in by 1½ in by 4 ft. The width and thickness vary somewhat in different mills. There is a new lath on the market, which is only 32 in long and which costs from $1.75 to $2 less than the 48-in lengths. Laths are sold by the thousand, in bunches containing 100 laths, from $4.50 to $5.50 being about the average prices. (Pre-war prices.)

Metal Lathing. (See Chapter XXIII, pages 883 to 887.)

Plastering on laths is generally done in three coats.* The first coat is called the SCRATCH-COAT; the second, the BROWN COAT, and the third, the WHITE COAT, SKIM-COAT, or FINISH. On brickwork or stonework the scratch-coat is generally omitted. For first-class work each coat should be permitted to dry thoroughly before the next coat is applied, and under no circumstances should the finish-coat be applied before the brown coat is thoroughly dry.

Drawn Work is a brown coat applied to a scratch-coat from the same staging, immediately after the scratch-coat is applied. It is a little cheaper than DRY SCRATCH, and much of it is done in the Western States.

The Scratch-Coat should always be made rich in lime, and should contain 1¼ bu of hair, or an equivalent quantity of fiber to each cask of lime, or 1 bu of hair to 2 of lime. A proportion of one part lime-paste to two parts of sand will require 1 cask (2½ bu) of lime to 5½ bbl of screened sand.

The Brown Coat should contain 1 cask (2½ bu) of lime to 7 bbl of screened sand, and 1 bu of hair to 5 of lime. Very little plaster is mixed by measure, however, the usual custom being to mix as much sand with the slaked lime as the mortar-mixer thinks it will stand and give satisfaction, the tendency being always to make the lime go as far as possible.

The Third or Finishing Coat is designated by various terms, such as SKIM-COAT, WHITE COAT, PUTTY-COAT, SAND-FINISH, etc. The skim-coat as used in the

* In the Eastern States, dwellings of moderate cost are generally plastered with two-coat work, the first or scratch-coat being brought nearly to the grounds, and carefully [illegible]ed to receive the skim-coat.

Eastern States is generally composed of lime-putty and washed beach-sand in equal proportions.

Sand Finish, which has a rough surface resembling coarse sandpaper, is mixed in the same way, only that coarser sand and more of it is used, and it is finished with a wooden or cork-faced float.

White Coating or Hard Finish generally means a composition of lime-putty and plaster of Paris, to which marble-dust is sometimes added. Plaster of Paris and marble-dust when used should not be mixed with the lime-putty until a few moments before using, and no more should be prepared at one time than can be used up at once, as it soon SETS, after which it should not be used. The skim-coat or hard finish should be finished with a steel trowel and wet brush. The more the work is troweled the harder it becomes. A superior hard finish is obtained by mixing 4 parts of Best's Keene's cement to 1 part lime-putty.

Mortar for Plastering. To make sure that the lime is well slaked, it is customary to require that the mortar for plastering shall be mixed at least seven days before it is used.

Hair such as is used by plasterers is obtained from the hides of cattle, and after being washed and dried is put up in paper bags, each bag being supposed to contain 1 bushel of hair when beaten up. Each package is supposed to weigh from to 8 lb but the weight often falls short. ASBESTOS and MANILLA FIBER are both used in place of hair; they are cleaner than hair and are said to be less injured by the lime. It is much better to add the hair to the lime-paste AFTER IT IS COLD and before mixing in the sand, as hot lime, and the steam caused by the slaking, burn or rot the hair so as to greatly weaken it. The common practice is to put the hair in the mortar-box, run off the hot lime as soon as it is slaked, throw in the sand and mix the whole together. It is then thrown out of the box into a pile and a new batch mixed up.

Machine-Made Mortar. In several of the larger cities plants have been equipped for the mixing of mortar by machinery. Machine-mixed mortar should be much better than the ordinary hand-mixed mortar, for the reason that time can be given for the lime to slake, the lime and sand can be accurately measured, and the hair and lime are not mixed with the lime until just before delivery. The mixing may also be more thoroughly and evenly done by machinery than is possible by hand.

Improved Wall-Plasters. Owing to the difficulty of obtaining sufficient space in building operations in central sections of large cities to properly slake sufficient lime mortar to carry on the plastering with the necessary speed, other kinds of plastering materials have come into existence in recent years. These are known as GYPSUM PLASTERS OF HARD-WALL PLASTERS. The base of these products is calcium sulphate or gypsum which has been calcined to partially expel the water. The setting and hardening of these products is dependent upon their combining chemically with the gauging water and crystallizing in the same chemical form as the material possessed before calcination. All hard-wall plasters contain material added for the purpose of controlling the SET. The straight calcined gypsum sets in a very few minutes, which time would be entirely too short to permit the workmen to apply the plaster to the wall and straighten it up before it had set. These plasters are characterized, also, by their inability to carry as much sand as lime mortar. Many of them contain other substances, such as clay or hydrated lime, added to improve their PLASTICITY. Hard-wall plasters manufactured in the eastern part of the United States from rock-gypsum invariably contain 15%, more or less, of clay or hydrate, added for this purpose. Plasters made in Kansas, Oklahoma, Texas and other

Western and Southwestern States are made from earth-gypsum. In the case of these materials, clay and hydrated lime are not added, for the reason that the earth-gypsum contains considerable clay matter, which renders further additions unnecessary.

Use of Hard-Wall Plasters. Hard-wall plasters are found to be very convenient in cases where space and time are the most important elements in the building operation. They set more rapidly than lime plasters, thus permitting the white coating and finishing of the job to be completed earlier. While hard-wall plasters become extremely hard, this property is sometimes considered objectionable, as it may give rise to what is called the SOUNDING-BOARD effect.

Keene's Cement Plasters. As distinguished from the ordinary hard-wall plasters, there exists another class of gypsum-products which, however, are somewhat different in the method of preparation and behavior. In the manufacture of these materials, the gypsum is calcined, immersed in a bath of alum or similar chemical and recalcined. The name KEENE'S CEMENT is usually applied to these materials, which are made by several manufacturers in this country. These are slow-setting and ultimately attain great strength and hardness. Keene's cement is generally used with considerable lime-putty or hydrated lime. The use of equal parts of hydrated lime and Keene's cement in making a plastering material is often recommended and found in specifications. (For Alca lime used as a wall-plaster, see page 1553.)

Advantages of Improved Wall-Plasters. Among the advantages gained by the use of these plasters are uniformity in strength and quality, extra hardness and toughness, freedom from pitting, saving in time required in making and drying, minimum danger from frost while being applied and before set, less weight and moisture in the building, and, in some cases, greater resistance to the action of fire.

Measuring Plasterers' Work. Lathing is always figured by the square yard and is generally included with the plastering, although in small country towns the carpenter often puts on the laths. Plastering on plane surfaces, such as walls and ceilings, is always measured by the square yard, whether it is one-coat, two-coat, or three-coat work, or lime or hard plaster. In regard to deductions for openings, custom varies somewhat in different parts of the country and also with different contractors. Some plasterers allow one-half the area of openings for ordinary doors and windows, while others make no allowance for openings of less than 7 sq yd.

Miscellaneous Details. Returns of chimney-breasts, pilasters and all strips less than 12 in in width should be measured as 12 in wide. Closets, soffits of stairs, etc., are generally figured at a higher rate than plain walls or ceilings, as it is not as easy to get at them. For circular or elliptical work, domes or groined ceilings, an additional price is made. If the plastering cannot be done from trestles an additional charge must be made for staging. Whenever plastering is done by measurement the contract should definitely state whether or not openings are to be deducted, and a special price should be made for the stucco-work, based on the full-size details.

Cornices and Moldings. Stucco cornices and molded work are generally measured by the superficial foot, measuring on the profile of the molding. When less than 12 in in girth they are usually rated as 1 ft. For each internal angle 1 lin ft should be added, and for external angles, 2 lin ft. For cornices on circular or elliptical work an additional price should be charged. Enriched moldings are generally figured by the linear foot, the price depending upon the design and size of the mold.

Quantities of Materials for Lathing and Plastering

Miscellaneous Data. To cover 100 sq yd requires from 1 400 to 1 500 laths, or say 1 450 for an average job, and 10 lb of threepenny fine nails.

Three-coat plastering on wooden laths, plaster-of-Paris finish, will require from 10 to 12 bu of lime, 1½ cu yd of sand, 2 bu of hair and 100 lb of plaster of Paris per 100 sq yd.

If the finish-coat is omitted, deduct 2 bu of lime and all of the plaster of Paris.

If sand-finished, omit the plaster of Paris and add ½ cu yd of sand.

To cover 100 sq yd with two coats on brick or stone walls, the brown coat and finishing coats, will require from 8 to 10 bu of lime, 1½ cu yd of sand, and 100 lb of plaster of Paris, to 100 sq yd.

Using Best's Keene's cement for brown mortar and Keene's finish on expanded-metal lath will require, for brown mortar, 550 lb of cement, 5½ bu of lime, 2 cu yd of sand and 2 bu of hair; for the finish, 300 lb of cement and 1 bu of lime per 100 yd.

Hard plasters on expanded-metal lath, plaster-of-Paris finish, require, for brown mortar, 2 000 lb of plaster and 2 cu yd of sand; for the finish, 1 bu of lime and 100 lb of plaster of Paris per 100 yd.

Cost of Lathing and Plastering. The average price for putting on wooden laths, labor only, is 4¾ cts per yard. For expanded or sheet-metal laths on wooden studding, 5¾ cts; on steel studding, wired, from 10 to 12 cts.

The cost of putting three coats on laths, plaster-of-Paris finish, labor only, runs about 22 cts per yard.

With sand finish the cost is about 23 cts.

These figures are based on plasterers' wages at 75 cts per hour, and 50 cts per hour for hod-carriers and mortar mixers.

The following schedule * gives the average cost of different kinds of plastering, based on lime at 40 cts per bushel, sand at 75 cts per load of 1¼ cu yd, hair at 40 cts per bushel, plaster of Paris at 50 cts per 100 lb.

Scratch and brown coat (lime) on wooden laths	25 cts per sq yd.
Three coats (lime) on wooden laths, plaster-of-Paris finish	30 cts per sq yd.
Three coats (lime) on wooden laths, sand finish	30 cts per sq yd.
Brown coat and finish on brick walls	23 cts per sq yd.
For hard-wall plaster instead of lime, add	3 cts per sq yd.
Three coats (lime), plaster-of-Paris finish, metal lath on wooden studding	65 cts per sq yd.
Three coats (lime) plaster-of-Paris finish, metal lath on steel studding	68 cts per sq yd.
For Keene's cement finish, add	10 cts per sq yd.
For blocking in imitation of tile, add	50 cts per sq yd.
Two coats hard-wall plaster, plaster-of-Paris finish, metal lath, wooden studding	70 cts per sq yd.
Two coats hard-wall plaster, plaster-of-Paris finish, metal lath on steel studs	73 cts per sq yd.
For Keene's cement finish, add	10 cts per sq yd.
Portland cement, brown coat, finished with Keene's cement blocked in imitation of tile, 3 by 6 in	$2.80 per sq yd.
For running base, 9 in high, in Best's Keene's cement	10 cts per ft.

For running plain moldings in plaster of Paris, from 3 to 5 cts per inch of girth.

For finishing shafts of columns, from 16 to 24 in in diam., from 12 to 14 ft high, $3 per column (labor only).

* These are pre-war prices and the unit values per sq yd must be largely increased on account of the increase in wages and materials.

These prices, of course, vary somewhat in different sections of the country. In some localities prices for materials or labor are less, in others higher.

Staff is a composition of plaster of Paris and hemp-fiber, cast in molds and nailed or wired in place. All of the buildings of the Columbian Exposition at Chicago (1893) were covered with this material and all of the temporary buildings of the St. Louis Exposition (1904). It is not sufficiently durable for permanent work unless it is frequently painted. The cost of staff, as used on the buildings at Chicago in 1893, varied from $2 to $2.25 per sq yd.

DATA ON LUMBER AND CARPENTERS' WORK*

Relative Hardness of Woods. Taking shell-bark hickory as the highest standard of our forest-trees, and calling that 100, other trees will compare with it for hardness as follows:

Shell-bark hickory	100	Yellow oak	60
Pignut hickory	96	Hard maple	56
White oak	84	White elm	58
White ash	77	Red cedar	56
Dogwood	75	Wild cherry	55
Scrub-oak	73	Yellow pine	54
White hazel	72	Chestnut	52
Apple-tree	70	Yellow poplar	51
Red oak	69	Butternut	43
White beech	65	White birch	43
Black walnut	65	White pine	30
Black birch	62		

Weight of Rough Lumber per 1 000 Feet

BOARD-MEASURE, APPROXIMATE

For weight of various woods see tables on pages 1501 to 1508

Kind of wood	Green from saw, lb	Shipping-dry, lb	Well-seasoned, lb	Kiln-dried, lb
Ash				
Chestnut	4 600	....	3 500	3 200
Hemlock	4 200	3 000	....	......
Maple, hard	5 400	4 150	3 900	3 400
Maple, soft	5 000	3 650	3 300	3 000
Oak, red	5 500	4 250	4 000	3 400
Oak, white	5 700	4 500	4 100	3 600
Pine, long-leaf	4 500	3 500	....	....
Pine, white	3 500	2 500	2 400	2 200
Poplar	4 000	3 000	2 900	2 400
Spruce	3 150	2 700	2 300	2 200
Sycamore	4 750	3 200	3 000	......
Walnut, black	4 900	4 000	3 800	....

* A comprehensive booklet giving the rules for the grading and classification of yellow pine lumber and dressed stock may be obtained from The Southern Pine Association, New Orleans, La.

Framing-Lumber may commonly be purchased in any of the following nominal sizes, except that common pine, spruce, and hemlock cannot usually be obtained in larger sizes than 12 by 12 in.

Nominal Sizes of Framing-Lumber

in	in	in	in
2 × 4	3 × 6	4 × 12	8 × 12
2 × 6	3 × 8	4 × 14	8 × 14
2 × 8	3 × 10	6 × 6	10 × 10
2 × 10	3 × 12	6 × 8	10 × 12
2 × 12	3 × 14	6 × 10	10 × 14
2 × 14	3 × 16	6 × 12	10 × 16
2 × 16	4 × 4	6 × 14	12 × 12
2½ × 12	4 × 6	6 × 16	12 × 14
2½ × 14	4 × 8	8 × 8	12 × 16
2½ × 16	4 × 10	8 × 10	14 × 14
....	....	....	14 × 16

In some of the New England mills, the following sizes, also, are sawed: 2 by 3, by 5, 2 by 7, 2 by 9, 3 by 4 and 3 by 5 in. These sizes are not commonly carried n stock, and in most localities would have to be obtained by ripping larger izes. Most of the long-leaf yellow pine and Douglas fir is SHIPPED SURFACED NE SIDE AND EDGE, the actual dimensions being from ¼ in to ⅜ in, and someimes ½ in, scant of the nominal dimensions. When framing-lumber is required o be full to dimensions it should be ordered IN THE ROUGH, and a special contract nade on that understanding.

Lengths of Framing-Timbers. All timber is cut and sold in even lengths, as o, 12, 14 and 16 ft. Odd and fractional lengths are counted as the next higher ven length; consequently it is, in certain cases, possible and economical to plan uildings so that timbers of even lengths may be used without waste.

Measurement of Rough Lumber. All rough lumber is sold by the foot, OARD-MEASURE, one foot being the equivalent of a board 1 ft wide, 1 ft long, and in thick. To compute the board-measure in any board, plank, or timber, divide the nominal sectional area, in inches, by 12, and multiply by the length in eet. Thus the number of FEET in a 2 by 4-in scantling, 8 ft long = $(2 \times 4/12) \times 8 = 5\frac{1}{3}$ ft, board-measure. A 10-in board, 12 ft long, contains $(1 \times 10/12) \times 12 = 10$ ft, board-measure. Extensive tables are published showing the feet, in oard-measure, for almost any commercial size of timber. The following table, owever, although compact, will enable one to readily estimate the number of EET in any of the standard sizes of boards, planks, or timbers. To use the table, nd the product of the lateral dimensions of the cross-section; then in the olumn having a heading equal to this product, and in the horizontal line opposite the given length will be found the number of feet in board-measure. Thus, or a 3 by 4, 2 by 6, or 1 by 12-in timber look in the column headed 12; for a 2 y 12, 4 by 6, or 3 by 8-in piece, look in the column headed 24. For lengths not iven in the table, take either twice the length and divide by 2, or one-half the ength and multiply by 2. Where timbers of the same size abut end to end, it conomizes labor in reducing to board-measure to take the full length; for this eason the lengths in the table are carried beyond those for single sticks.

Table of Board-Measure

For explanation, see page 1559

* The measurements in these columns come out in even feet.

Measurement of Finishing-Lumber, Flooring, Ceiling, Etc. Most, if not l, lumber for finishing is sawed for use in thicknesses of 1 in, 1¼ in, 1½ in, and in, and some woods, such as white pine and poplar, are sawed into thicknesses 2½ in and 3 in.

When surfaced both sides, the thickness is reduced to 13/16, 1 1/16, 1 5/16, 1¾, 2¼, d 2 11/16 in.

All dressed stock is measured and sold STRIP-COUNT, that is, full size of rough aterial necessarily used in its manufacture. Thus 1 1/16-in boards are measured though 1¼ in thick. The number of feet, board-measure, for 1¼-in stock 1/16 finished) is 1¼ times that in a 1-in board, and in the same way for 1½-in d 2½-in stock. 1¾-in planks are always measured 2 in thick, and 2¼-in ock, 2½ in thick. Boards less than 1 in thick are measured the same as 1-in ards, but for ⅜-in and ⅝-in stock a reduced price is generally made.

Matched Ordinary Flooring.* The standard sizes for flooring (other than rdwood, parqueting or parquet-flooring) are 1 by 3, 1 by 4 and 1 by 6; or 1¼ by 1¼ by 4 and 1¼ by 6. The thickness of 1-in flooring should be 13/16 in, and 1¼-in flooring, 1 3/32 in. 3-in flooring should show 2¼ in on the face, after it is d; 4-in, 3¼ in; and 6-in, 5¼ in.

Matched Maple Flooring is usually made in 2-in, 2¼-in and 3¼-in face, and thicknesses of 13/16, 1 1/16 and 1 5/16 in.

Ceiling, matched and beaded boards, is regularly stuck in the same widths as oring. The standard (nominal) thicknesses of yellow-pine ceiling are ⅜, ½, and ¾ in, the actual thickness of each being 1/16 in less. The ⅜-in ceiling is essed one side only, the other thicknesses both sides.

Yellow Pine Drop-Siding. Dressed and matched yellow pine drop-siding is by 3½ and ¾ by 5½ in, showing 3¼ and 5¼-in face; and worked shiplap is by 3½ and ¾ by 5½ in, showing 3 and 5-in face.

Beveled Siding is resawed on a bevel from stock 13/16 by 3½ and 13/16 by 5½ in, er surfacing.

New England Clapboards are 4 ft long, 6 in wide, ½ in thick at the butt, and out ⅛ in thick at the other edge. They are put up in bunches and sold by the ousand.

Rules for Estimating Quantities of Sheathing, Flooring, Etc. For com- n sheathing laid horizontally on a wall or roof without openings, add one- th to the actual superficial area to allow for waste. On the walls of dwellings, ure the walls as though without openings and allow nothing for waste. If athing is laid diagonally, add one-sixth to the actual superficial area.

For tight sheathing laid horizontally, add one-fifth for 6-in boards, one-seventh 8-in boards, and one-ninth for 10-in boards. If laid diagonally add one- rth for 6-in boards, one-sixth for 8-in boards, and one-eighth for 10-in boards.

For 3-in matched flooring add one-half to the actual superficial area to be vered.

For 4-in flooring add one-third and for 6-in flooring add one-fifth. Ceiling is asured the same as flooring.

For drop-siding, add one-fifth to the superficial area.

For lap-siding, laid 4 in to the weather, add one-half to the actual superficial a; if 4½ in to the weather, add one-third.

* Everywhere except in New England FLOORING is always understood to be tongued and oved.

Cost of Labor for Carpenters' Work. There are so many items and co ditions which enter into the cost of carpenters' work, and the cost varies widely with the locality, that it is quite impossible to give figures which are general practical value, although several books * have been published on es mating labor and materials for buildings.

The following figures of the cost,† for labor and nails, of framing and putti on sheathing and siding and laying flooring were computed on the basis of ca penters' wages at $3 a day of eight hours (37½ cts per hour). The cost framing is almost always figured at a certain price per thousand feet of lumb board-measure. The cost of laying flooring, sheathing, etc., is almost alw figured by the square of 100 sq ft (10 by 10 ft).

Character of work	Cost
For setting up studding and framing walls of wooden dwellings	$10.00 per 1000
For framing and setting floor-joists, 2 by 8 to 2 by 12	$9.00 to $10.00 per 1000
Framing and setting heavy joists and girders, 6 by 12 to 10 by 14	$ 8.50 per 1000
Framing gable roofs and setting in place	10.00 per 1000
Framing hip-roofs and setting in place	$11.00 to $12.00 per 10
For putting in bridging, after it is cut, per 100 lin ft in the row	$1.25
For covering the sides or roofs of wooden buildings with dressed sheathing, laid horizontally	60 cts per square
The same, if laid diagonally	75 cts per square
The cost of labor and nails for laying 6-in flooring, blind-nailed to every joist, without dressing after laying, is about	$2.00 per square
For 4-in flooring, not dressed, allow	2.25 per square
For 3-in flooring, not dressed, allow	2.50 per square
For 3-in hard-pine flooring, hand-smoothed or traversed.	3.75 per square
For 3-in red-oak flooring, hand-smoothed or traversed	6.00 per square
For 3-in white-oak flooring, hand-smoothed or traversed	8.00 per square
For 3-in maple flooring, hand-smoothed or traversed	$10.00 to $12.00 per sq

BUILDING PAPERS, BUILDING FELTS AND QUILTS

Sheathing-Papers,‡ Felts, Quilts, Etc. It is well known that frame bui ings when merely sheathed and clapboarded or shingled on the outside and simpl lathed and plastered on the inside, are almost sure to be hot in summer and co in winter; and as the wood almost always shrinks, cracks result through whi the wind finds its way. For these reasons some extra provision should be mad for keeping out the wind and the heat and cold; and it is generally admitted th

* Readers are referred to The Building Estimator's Reference Book, by F. R. Walk The New Building Estimator, by William Arthur, Handbook of Cost Data, by H Gillette and the Estimators' Price Book, by I. P. Hicks. To all of these, architects a builders are referred for detailed information and valuable data on costs of labor a material.

† The wages of carpenters varied (1916) in the United States from 35 to 70 cts per ho or from $2.80 to $5.60 per day of 8 hours. For rates per day higher than those giv the figures showing the costs in the schedule must be raised proportionately.

‡ The terms BUILDING PAPER and SHEATHING-PAPER are by the public indiscriminat applied to all kinds of paper used in connection with building-construction. In t trade, however, the term BUILDING PAPER is confined to the rosin-sized and chea grades of paper, while the heavier and better grades are classed as SHEATHING-PAPERS.

ere is no material that will do this so well and at so small an expense as good athing-papers or sheathing-felts. The papers made for this purpose are comnly known as SHEATHING-PAPERS or BUILDING PAPERS. There is a great riety of sheathing-papers manufactured, many of them of great excellence, d even the best are comparatively inexpensive, costing only about $1.00 per o sq ft; so that only the better qualities of any kind of felt or paper should be ecified. Where the cost of the sheathing-paper on an ordinary house is only ew dollars, it is poor economy to use a cheap paper, as the labor of applying it an important item and the poorer the paper the more difficult the work of putg it on. The qualities which good sheathing-paper should possess are permence, impenetrability to air and water and sufficient strength to permit of plying without tearing. Protection or proof against vermin and insects is other important requirement. It should not be brittle nor have a lasting ong odor and, for the convenience of the builder, should be clean for handling. ere are so many papers possessing all or most of these qualities that it is deemed xpedient to mention particular brands. The architect should decide for himf, from the samples with which he has probably been furnished, what papers best adapted to the particular conditions; and he should then specify those ands, giving, also, the manufacturers' names, instead of leaving the choice to builder, who will be quite sure to be guided by price rather than by quality. any object to tarred or saturated sheathing-papers and felts because of their idency to become brittle and because they emit a strong odor and are someat disagreeable to handle. On the other hand, the advocates of tarred felts phasize their cheapness, warmth and even their odor, which makes them rmin-proof. The odor gradually disappears after the clapboards, siding or ngles are put on and the inside walls finished. Sheathing-paper is usually plied just previous to putting on the clapboards, siding, or shingles. It is nerally placed horizontally and should lap about 2 in over each sheet and over paper previously placed around the window and door-frames. If sheathinglt or similar material is to be placed under the clapboards or siding, laths ould be nailed vertically over it, opposite each stud, and the siding or claprds nailed to the laths; otherwise it will be difficult to put them on evenly, ing to the thickness and elastic quality of the QUILT. Shingles, however, may applied directly over it. Sheathing-quilt possesses marked fire-resisting perties. The sheathing-paper and the labor of putting it on should be inded in the carpenter's specifications.

Rosin-Sized Building-Papers. These are the common grades of building per; they are not water-proof, and should not be used on roofs or on walls in np climates. In dry places they protect from dust, draughts, and to some ent from heat and cold. They are generally either a dull red or gray in color, re a hard, smooth surface, and are clean to handle. They are always put up rolls 36 in wide and usually contain 500 sq ft. The weight varies from 18 to lb to the roll of 500 sq ft.

Insulating and Deadening-Quilts. Among the insulating and deadeninglts much in use are those mentioned below. There are also other good maals in this line which are manufactured and used for insulating and deadening poses.

Sheathing-Quilt.* This consists of a felted matting of eel-grass held in place ween two layers of strong Manila paper by quilting. "The long, flat fibers eel-grass cross each other at every angle and form within each layer of quilt umerable minute dead-air spaces, that make a soft, elastic cushion. This

* Made by Samuel Cabot (Inc.), Boston, Mass.

gives the most perfect conditions for non-conduction." Eel-grass is cho for the filling because of its long, flat fibers, which especially adapt it f felting; because of its great durability,* and its resistance to fire; and beca owing to the large percentage of iodine which it contains, it is repellent to n and vermin. This quilt is made in single and double-ply thickness, and is p up in bales of 500 sq ft. It is also now made with a covering of asbestos, whi tenders it thoroughly fire-proof. The material is also very efficient for he insulation. When used for this purpose there is no objection to nails passi through it.

Keystone Hair Insulator. Another material used for similar purposes is t Keystone Hair Insulator.† This consists of thoroughly cleansed cattles' ha between two layers of strong, non-porous building paper, securely stitched t gether. The hair is chemically treated, so that it is coated with lime, whi makes the finished material vermin-proof and odorless.

Mineral-Wool Deadeners, which are fire-proof sound-deadening quilts rock-fiber wool stitched between two sheets of building paper or of asbest paper according to the grade desired, are made by the Union Fibre Company Winona, Minn., and other firms. This company makes, also, what is call Lith and Feltlino, which are sound-deadening materials in board form. Th manufacture, also, Linofelt, a building-quilt of flax-fibers (unbleached lin threads), stitched between water-proof paper or asbestos paper according to nee It is ¼ in thick. Linofelt for sheathing in place of ordinary building paper ad from 1 to 1½% to the cost of a house.

Felt-Papers. There are a great many felt-papers for lining floors and a fe are made fire-proof by means of chemicals. As a rule these felts are cheaper th Cabot's QUILT, although the saving in an ordinary residence would be but littl and even among the felts themselves there is quite a difference in cost. I choosing a felt-paper for lining, the architect should select one that is soft a elastic enough to form a cushion, and the thicker the felt, provided it has th above qualities, the greater will be its non-conduction. Some felts are ma water-proof by an asphalt center, which is an advantage in case of fire or leak but some authorities think that it is doubtful if such felts obstruct the passage sound as well as felts without the asphalt center. The experience of so acoustical experts seems to show that one of the best methods of deadening is t a combination of heavy hair-felt or felt-paper with sheets of galvanized iro Two layers of felt, each from ½ to 1 in thick, are placed on either side of a sing layer of galvanized iron, the latter resting freely between the felt layers. Th form of construction is to be preferred where the deadening-material is not a tached to the enclosing woodwork. An additional layer of iron and of fe increases the effectiveness of the combination.

Saturated Felts.‡ Common roofing-felts are made by saturating comm dry felt with coal-tar pitch. Roofing-felts are commonly made in weights of 1 15, and 20 lb to the 100 sq ft. Nothing lighter than 12 lb should be used f roofing. They are usually sold by weight. Asphalt-felts are commonly ma in the same weights.

Dry Saturated Tarred Felts are specially run through a tier of calend to give a hard, uniform surface and contain a minimum amount of coal-ta

* A sample of eel-grass 250 years old and in a perfect state of preservation, may be se at Mr. Cabot's office.

† Made by Johns-Manville, Inc., New York.

‡ The Barrett Company and other manufacturers make numerous brands of the sheathing and roofing-papers.

ey are especially adapted for slaters' use, as they will carry a chalk line and e easy to handle. The rolls are 36 in wide, contain 500 sq ft and weigh about lb.

Asbestos Building Felts are usually made about 6, 10, 14 and 16 lb to the o sq ft, although different manufacturers make different weights. They come rolls 36 in wide and are sold by weight.

Sound-Deadening Felts. These deadening-felts are made by various manuturers. In one of these felts * the material itself is rather hard and thin, but s pressed in such a way as to form small indentations or air-cells. This makes lastic and breaks up the sound-waves.

Asbestos Sheathing. Sheathing-papers or building felts, made of asbestos, used to a considerable extent for floor-linings and for covering the outside lls of wooden buildings, principally on account of their fire-proof and verminof qualities. These papers are well known in the trade and can be procured hout difficulty. They are supplied by the manufacturers in 50 or 100-lb s, 36 in wide, on a basis of the following scale of weights:

4 lb to the 100 sq ft	18 lb to the 100 sq ft
6 lb to the 100 sq ft	20 lb to the 100 sq ft
8 lb to the 100 sq ft	24 lb to the 100 sq ft
10 lb to the 100 sq ft	32 lb to the 100 sq ft
12 lb to the 100 sq ft	1/16 in thick
14 lb to the 100 sq ft	3/32 in thick
16 lb to the 100 sq ft	1/8 in thick

he sheathing in the 1/16, 3/32 and 1/8-in thicknesses is used only for special pures where an unusually thick lining is desired for possible fire-protection und exposed flues, for chimney-breasts, etc. When the weight of paper exls 32 lb to the square foot it is known as ROLL-BOARD and is no longer classed weight per 100 sq ft, but by thickness. For floor-linings, 16-lb paper is genly employed, this weight being sufficiently thick and strong to resist ordiy damage in application and in handling. Asbestos felts and building papers ear to have approximately the same effect in retarding the passage of soundes as other felt-papers of a relatively similar thickness and quality, while r fire-proof and vermin-proof qualities are a distinct advantage. The cost of stos paper and building-felt, while somewhat greater than that of the ordi- papers used for similar purposes, is not excessive. The market price varies depends upon the fluctuations of the market. For example, the cost of sq ft of 16-lb asbestos paper varied from 32 to 40 cts, according to the ket, before the war.†

ater-Proof Papers. Neponset Black Sheathing is water-proof and roof, odorless and clean to handle, and is an excellent paper under g, shingles, slate, or tin. The rolls are 36 in wide, containing 250 and sq ft.

eponset Red Rope Sheathing and Roofing. This is made of rope-, has great strength and flexibility, and is absolutely water-proof and air-. It is one of the best sheathing-papers and makes a good cheap roofing heds, poultry-houses, etc. The rolls are 36 in wide, containing 100, 250 and sq ft.

Neponset Florian Sound-Deadening Felt, supplied by Bird & Son, East Walpole,

† These prices are now much higher.

Parchment Water-Proof Sheathing. There are various parchment-sheat ings on the market which are semitransparent, have smooth surfaces, and odorless, water-proof, air-proof and vermin-proof. They are adapted for gen sheathing purposes. In general 1-ply weighs 25 lb to 900 sq ft; 2-ply, 25 lb 500 sq ft; 3-ply, 25 lb to 275 sq ft. They are 36 in wide.

Cost of Building and Sheathing-Papers in Place.* The following, though necessarily restricted to a few lines, will give a general idea of the cost different kinds and grades of sheathing-papers, the prices given being fair av ages for the materials APPLIED to an outside wall or roof:

	Price per 100 square feet
Common tarred felts (15 lb per square)	30 cts
Red rosin-sized sheathing, best grades	25 cts
Monahan's parchment-sheathing, single-ply	26 cts
Monahan's parchment-sheathing, double-ply	40 cts
Monahan's ship-rigging tar-sheathing, 2-ply	75 cts
"Neponset" black (water-proof) paper	45 cts
"Neponset" red-rope roofing	$1.20
Sheathing-papers with asphalt center	40 to 50 cts
Asbestos building or sheathing-felt, 10 lb per square	22½ cts
Asbestos building or sheathing-felt, 14 lb per square	31½ cts
Cabot's sheathing-quilt, single-ply	$1.05
Cabot's sheathing-quilt, double-ply	$1.25
Barrett's specification-felt	35 cts
Barrett's DEFENDER, felt-sheathing	80 cts
Sackett's water-proof sheathing	30 cts
Empire parchment-sheathing, 1-ply	25 cts
Empire parchment-sheathing, 2-ply	36 cts
Empire parchment-sheathing, 3-ply	50 cts
Barrett's red rope	$1.00
Barrett's black, water-proof sheathing	40 cts

PAINT AND VARNISH †

Pigments and Vehicles. The solid ingredient of a paint is called the PIGMENT and is a fine powder, nearly all of which will pass through a brass-wire sieve 100 meshes to the linear inch; in fact, most pigments are much finer than this and those formed as precipitates by chemical processes are so fine that there no way to measure them. The liquid part is called the VEHICLE. This is us ally linseed-oil, sometimes with the addition of a little turpentine or other volatil solvent. In the enamel paints it is varnish and in kalsomine and other cold water paints it is a solution of glue, casein, albumen, or some similar cementi material. The cementing material is sometimes called the BINDER.

Ingredients of Oil-Paint. White lead and white zinc are the common whi pigments. There are white pigments of variable composition called leaded zi and zinc lead, furnace-products, composed of zinc oxide and lead sulph There is also a basic lead sulphate, commercially called sublimed white lea which is a similar furnace-product consisting chiefly of sulphate of lea These composite white pigments are largely used in mixed paints. LITHOPO is a mixture of sulphide of zinc and sulphate of barium. It is very white, a

* All prices quoted are pre-war prices and the data are retained for purposes of co parison and relative values.

† The editor is indebted to Professor Alvah H. Sabin for valuable assistance in t ... of the data relating to this subject.

ıd opaque and largely used as the basis of flat wall-finishes for interior work, ıt is not durable for exterior work. It is discolored (grey) by strong light, but ıis is not a very serious practical objection. White lead is used everywhere, ıt tends to yellow somewhat in the dark. White zinc is chiefly used on interior ork, being the whitest paint known. Both are often mixed and both are used mixed paints. Yellow paint is commonly chromate of lead, or chrome yellow; 'een is chrome green, which is a mixture of chrome yellow and Prussian blue; ue is ultramarine, or sometimes Prussian blue. The brilliant reds are coal-tar lors as a rule; the dull reds and browns are oxides of iron. Ochres are dull ellow. Carbon forms the base of all black paints, either as lampblack, drop-ack (boneblack), or graphite. Linseed-oil is either raw or boiled. Raw oil is ıe oil in its natural state as it is extracted from the seed; it should be settled ıd filtered perfectly clear; it is yellow or greenish yellow in color. Boiled oil is w oil which has been heated to 400° or 500° F. with compounds (usually oxides) lead and manganese; it is darker in color than raw oil, and dries quicker. aw oil exposed in a thin film to the air is converted in about five days into a ugh leathery substance; boiled oil undergoes this change in from 10 to 24 hours.

Driers. These are compounds of lead and manganese, dissolved in oil, and is solution thinned with turpentine or benzine. They act as carriers of oxygen tween the air and the oil, and their addition to a paint makes it dry more pidly. Some driers are also called JAPANS. Not more than 10% by volume of y of these liquid driers should be added to oil. Excess of drier causes the int to lack durability. Cheap driers often contain rosin. It is well to specify at driers and japans should be free from ROSIN (not resin, as varnish-resins are esent in some of the best driers).

Priming Coat. This is the first coat applied to the clean surface. A priming at for wood is chiefly oil, and is usually equivalent to a gallon of ordinary paint inned with a gallon of raw linseed-oil. Paint, however, is not thinned to make priming coat for structural metal. In all wood-work, nail-holes and other de-ts are filled with putty after the priming coat has been applied; but if the od is resinous, knots and resinous places must be covered with shellac varnish fore the priming coat is put on. Pitchy woods, such as southern yellow pine d cypress, do not readily absorb oil, and turpentine should be substituted for rt of the oil. Red lead is successfully used as a primer (2 parts to 1 of white d) on such woods; this is the standard practice in England, and is better than use of all white lead.

Outside Painting. The priming coat having largely been absorbed by the od, a second and third coat of paint are to be applied. The most common nt used on houses is white lead. This is commonly sold as paste white lead, taining 8% of oil; 100 lb of this is equal to 2.8 gal in volume, and is commonly xed with 3½ gal of raw linseed-oil, 1 qt of turpentine and 1 pt of drier to make gal of paint for the second coat; or with 4 gal of oil, 1 pt of turpentine and 1 of drier for the finishing coat. If white zinc is used, 9½ lb of dry zinc oxide 5.7 lb of oil make 1 gal of paint; to this, turpentine and drier should also added. White lead, after about a year, begins to CHALK, that is, its surface omes dry and chalky; this does not indicate failure, however, and it makes a d surface for repainting. Finely reticulated checking, not extending through film, occurs later, and when sufficiently marked indicates need of repainting. any paint, when cracks begin to extend through to the wood, repainting is ed for; these cracks occur sooner on pitchy woods. White zinc, if used alone outside (not inside) work, is very hard and tends to peel off. MIXED PAINTS epared proprietary paints) generally contain zinc mixed with either white l or some of the pigments based on basic lead sulphate, and some auxiliary

* The measurements in these columns come out in even feet.

a fire. It is especially suitable for cleaning out moldings and all irregular sur-faces from which the varnish may then be removed with stiff brushes, if it is not convenient to use scrapers. It is especially desirable to have floors occasionally cleaned in this way; but if a house has been varnished originally with a first-class varnish it may be necessary only to wash it thoroughly and then apply another coat of varnish. Smoke and dirt may often be thoroughly removed from ceilings with the crumbs of fresh bread, where washing would not be desirable. A 10% solution of carbonate of soda (sal soda) in hot water may be used to remove old floor-wax.

The Painting of Structural Steel. Steel being usually more perishable than wood, as well as more expensive, and used for service where its strength is essential to the stability of the structure, its protection from corrosion by painting is of much importance. It must first of all be recognized that the precautions always taken in painting wood, to secure a clean surface for the paint, must not be omitted with steel. Mud and dirt must first be removed from the steel; then it must be examined for rust, and any rust-spots must be thoroughly cleaned. Loose scale may be removed with wire brushes, but thick and closely adherent rust must be removed with steel scrapers, or with hammer and chisel if necessary. No doubt the best way to clean steel is to use the sand-blast, but it is not available for much architectural work. In any case much care must be taken to obtain a clean surface. On wood the priming coat sinks into the wood and forms a perfect bond between it and the succeeding coats; but on metal no such thing is possible and it is a case of simple adhesion, which demands a clean surface for efficient results. The paint for structural metal should be tough and elastic, and to as great a degree as possible it should be water-proof. Less than two coats should never be applied, and three are better. Paint is always thin on edges and angles, and also on bolt and rivet-heads; it is therefore good practice, after the first full coat, to apply a partial or striping coat, covering the angles and edges and the surface for at least 1 in back from the edges, and covering all bolt-heads and rivet-heads. After this striping coat has become dry, the second full coat is applied, and it may then be assumed that the whole surface has received two full coats. At least a week should elapse between coats. In designing the steelwork, all cavities which may be filled with rain during erection should be properly drained; and during erection all small cavities should be filled with cement, and all contact-surfaces thickly painted.

Kinds of Paint for Structural Steel. RED LEAD is more generally used than anything else as a paint for structural steel. It is a "true red lead" (Pb_3O_4), usually made from litharge (PbO), and frequently containing from 10 to 20% of the latter. If it contains much litharge, it rapidly thickens when mixed with oil and finally hardens; this makes it a paint difficult to apply. If, however, the material from which it is made is reduced to a sufficiently fine powder before it is oxidized an almost completely oxidized red lead is produced, which is as easily worked as white lead, and better in every respect. The requirements of the government of the United States have for years called for red lead of not less than 94% of "true red lead" (Pb_3O_4), and the Navy Department, as well as several large railway companies, is now using large amounts of red lead which has not less than 98% of "true red lead." It may now be obtained in paste-form, similar to white lead and containing about 6½% of raw linseed-oil. 33 lb of red lead (dry pigment) to 1 gal of oil is the maximum and this is especially suitable for hydraulic work; 28 lb to 1 gal of oil (containing 20 lb of pigment in a gallon of paint) is more common; while 25 lb to a gallon of oil is a common requirement for railroad-specifications. Finely ground GRAPHITE in linseed-oil is a favorite paint for metal; it flows well, is easily applied, less expensive than red lead, and if well

made gives excellent results. Graphite is sometimes mixed with lampblack, probably with advantage. Boneblack is also an important ingredient of CARBON PAINTS. Formerly oxide of iron in linseed-oil was used more than all other paints for this purpose; but while many engineers still like it, its use has very greatly diminished. ASPHALTUM has been used and is still used, as a varnish either alone or in combination, and some of these asphaltic preparations are fairly satisfactory. The fact is, that a really competent paint-manufacturer can make a reasonably good paint out of any of these, and if the paint is carefully applied the results will be satisfactory. There are great differences in painters. In regard to the surface of structural steel covered by a gallon of paint, there is a great difference of opinion among experts. Some say from 300 to 400 sq ft, others 1000 or 1200 sq ft. The truth is that any paint may be brushed out into an exceedingly thin film by a skilled workman, while ordinary usage results in a film at least twice as thick. The general opinion is that it is not wise to estimate more than 400 sq ft to the gallon for one coat. Varnish-paints cover less than oil-paints, but if well made they are very durable.

Painting on Cement and Concrete. Cement and concrete-work are difficult to paint, because they are strongly alkaline and even caustic when new. Work in these materials should be allowed to stand a year or two if possible before it is painted; then it may be painted with any ordinary paint. A practice which has been highly recommended is to wash the surface, repeatedly if possible, with a strong solution of zinc sulphate, the sulphuric acid uniting with the free lime and the zinc being left in the pores as an oxide or hydrate. Some preparations for this purpose are on the market; and while some are probably good, others are to be distrusted. The best way is to allow the surface to age, if this is at all possible.

WINDOW-GLASS AND GLAZING *

Glazing. The glazing of windows originally belonged to the painter's trade, and when glass is broken, it is still customary to go to a painter to have it replaced; but custom has so changed in some parts of the country, that when new windows are to be glazed, the work is sometimes done at the mill or factory where the sashes are made, sometimes by the local glass-jobber in the town where the building is being erected, and again, in other localities, the glazing of new buildings is still done by the painter. COMMON WINDOW-GLASS is usually set with putty and secured with triangular pieces of zinc called GLAZIERS' POINTS, driven into the wood over the glass and covered with putty. In the best work, a thin layer of putty is first put in the rebate of the sash and the glass is then placed on it and pushed down to a solid bearing. This is called BACK-PUTTYING. The points are then driven about 8 or 10 in apart and the putty applied over the glass and points so as to fill the rebate. Outside windows should always be glazed on the outside of the sash. Common window-glass has a slight bend in it, the result of its original cylindrical shape; it should be glazed, therefore, with the convex side out, as this reduces to a minimum the effects of the waviness when looking through it either from the outside or inside. Plate glass, in window-sashes and door-lights, should be back-puttied and secured by wooden beads.

Leaded Glass. It was formerly a common practice for architects to name in the specifications a certain sum of money to be allowed by the carpenter for the leaded glass and to be expended under the direction of the architect. Where

* Condensed from article on Window-Glass and Glazing by Professor Thomas Nolan in Building Construction and Superintendence, Part II, Carpenters' Work, by F. E. Kidder.

clear glass was used, the pattern was sometimes shown on the drawings and the glass was specified in the same manner as any other work. When colored glass was to be used, it was customary to make a definite allowance and then to entrust the work to a good art-glass manufacturer. But leaded glass should be designed, furnished and put in place by those who are entirely familiar with its manufacture and its limitations; the purchase of the same should be left entirely in the hands of the owner; and no specification as to its price or make should be used by the architect. The colored-glass windows should show as much individual artistic taste as any other picture or decoration used in the building. The cheap and inartistic leaded glass is fast becoming a thing of the past and owners are confining themselves to purely works of art placed in some appropriate location in the building.

Sheet Glass. General Description. Common window-glass is technically known as SHEET GLASS or CYLINDER GLASS. "It is made by the workmen dipping a tube with an enlarged end in the molten glass or METAL until from 7 to 10 lb are gathered up. Then it is blown out slightly by the workman, taken on a blowing-tube and still further blown and manipulated, until a cylinder about 15 in in diameter and 60 in long is formed. This cylinder has the two ends trimmed off and is then cut longitudinally and gradually warmed. It is then placed on a large flat stone supported by a carriage, where it is heated until it softens sufficiently to open out flat; the carriage is then pushed into the annealing-chamber and the sheet taken off." About the year 1910, sheet glass blown by machinery, utilizing compressed air, was perfected, and the result has been a gradual decrease in its cost. The cylinder blown by compressed air is split open and flattened out in just the same manner and by the same process as in the mouth-blown cylinder.

Grades and Qualities of Sheet Glass. Sheet glass is graded as DOUBLE-THICK or SINGLE-THICK, and each thickness is further divided into three qualities, FIRST, SECOND, or THIRD, according to its relative freedom from defects. The price varies according to the strength and quality. It should be remembered that sheet glass is always wavy, the result of the flattening of the cylinder. Many suppose that by designating sheet glass, CRYSTAL-SHEET GLASS, SELECTED-SHEET GLASS, or SHEET GLASS FREE FROM WAVES AND IMPERFECTIONS, a sheet glass free from waves and blemishes can be obtained. The terms and names do not change the nature of this glass, which still remains sheet glass, characterized by the defects inherent in the method by which it is manufactured. To obtain a thin glass, free from waviness, plate glass, ⅛ in thick, sometimes known as CRYSTAL PLATE, or plate glass 3⁄16 in thick, must be specified. Since the improvement in the manufacture of window-glass in this country, scarcely any sheet glass is now imported for glazing purposes. A small amount of Belgian sheet glass is brought to this country and used along the Atlantic seaboard for picture-framing. The low prices of the American sheet glass, and its excellent quality, have practically forced imported sheet glass out of the market. All common sheet glass, without regard to quality, is graded according to thickness, as SINGLE-THICK or DOUBLE-THICK. The thickness of the double-thick glass is a scant ⅛ in while that of the single-thick averages about 1⁄12 in. It is customary to use the double thickness for sheet glass over 24 in in width. The best quality of sheet glass is specified as AA, the second as A and the third as B.

Sizes of Sheet Glass. The regular stock-sizes vary by inches from 6 to 16 in in width. Above that they vary by even inches up to 60 in in width and 70 in in length for double thickness, and up to 30 by 50 in for single thickness.

Cost of Sheet Glass. The prices for sheet glass, as for all other clear glass, vary wi[illegible] [illegible]ze, strength and quality. Prices are determined by a schedule

or price-list,* giving the price for each size, in both thicknesses, and all qualities; and from these prices a very large discount is allowed. Fluctuations in prices are regulated by the discount, the list usually remaining unchanged for a number of years. The price-list prevailing in 1913 was in use from October 1, 1903. The only way to ascertain the price of a light of glass of a given size is to find it from the price-list, from which the discount, quoted by the glass-dealer, must be deducted. For the benefit of the Pacific Coast trade there is a Western Glass List † which differs somewhat from the Eastern list. The list is for sheet glass, the plate glass lists being the same in the East and West. The price per square foot increases rapidly as the size of the pane increases, so that it is much cheaper to divide a large window into eight or twelve lights than into two lights. Compared with the cost of the building, however, the glass is a small item and in the better classes of buildings each sash is usually glazed with a single light of glass. In factories, workshops, etc., where there is usually a large amount of glass-surface, the size of the lights is not of so much importance, while the saving by using small lights is quite an item; hence twelve-light and even sixteen-light windows are generally used in such buildings. The following table shows quite clearly the relative cost (1913) per square foot of different-sized panes of American glass, the prices given being an average at that time for the whole country.

Comparative Cost (1913) of American Sheet Glass per Square Foot, Based Upon a Discount of 90 and 20 Per Cent on the List of October 1, 1903 ‡

Grades	Sizes of lights in inches						
	10×12	15×20	24×34	30×36	36×40	40×60	60×70
	Prices in cents per square foot						
Double strength:							
First quality......	7.0	8.3	9.4	10.0	10.8	14.0	29.2
Second quality....	6.0	7.3	8.3	9.0	10.0	14.4	27.0
Single strength:							
First quality......	5.0	4.8	6.4	6.8	......	......	......
Second quality....	4.3	4.5	5.6	6.0	......	......	......

Crystal-Sheet Glass, 26-Ounce. This glass is made by the cylinder-process, it is a little thicker than the ordinary double-strength glass. It is probably the best glass made, next to plate glass, but owing to the method of its manufacture is necessarily characterized by a wavy appearance. If good glass is required for first-class residences, hotels, office-buildings, etc., polished plate glass should be used. The latter invariably gives satisfaction, while sheet glass, no matter of what thickness, is usually disappointing in its appearance.

Defects of Sheet Glass. All sheet glass, when looked upon from the outside, has a wavy, watery appearance, like the surface of a lake slightly agitated by

* The price-lists of glass have been omitted as they can readily be obtained from the glass-dealers in any city. Such lists are not of much service unless they are complete; and the full lists are too long to be inserted in a condensed handbook.

† This list, with discounts from the prices given, may be obtained from the W. P. Fuller Company, San Francisco, Cal.

‡ Much valuable information in regard to Window-Glass and Glazing was furnished by Mr. S. C. Gilmore of the Hires-Turner Glass Company. Philadelphia, Pa.

the wind; and when the sunshine falls upon it the irregularity of the surface is greatly emphasized. This characteristic of sheet glass is due to its being made in the shape of a cylinder and then stretched or flattened out into a sheet, and it cannot be wholly avoided. Besides this universal defect, the cheaper grades are often STRINGY, BLISTERY, SULPHURED, SMOKED, or STAINED; so that, in looking through the glass, objects seen at a distance are deformed and distorted.

Plate Glass. General Description. Plate glass is commonly known as POLISHED PLATE GLASS because its surface is finely polished and thus made clear and transparent. It is more largely used every year for windows of fine residences, hotels and office-buildings, where transparency is desired from the inside and an elegant appearance required on the outside. The process of manufacture of plate glass is entirely different from that of sheet glass. In making plate glass the metal, which is prepared with great care, is melted in large pots and then cast on a perfectly flat cast-iron table. "The width and thickness of the plate is determined by means of metal strips called GUNS, which are fastened on, and on which a heavy, metal roller travels. The ends of the guns are tapered so that when the roller is at one extremity, it and the guns form three sides of a shallow, rectangular dish. The molten metal is poured on and the roller passed along slowly, forcing the metal in front of it and rolling out the sheet." The sheet is then annealed and forms what is known as ROUGH PLATE, which is used for vault-lights, skylights, floor-lights and the like. "For polished plate the rough plate is carefully examined for flaws, which are cut out, leaving the largest-sized sheet practicable. The plate is then fastened to a revolving table by means of plaster of Paris, and two heavy shoes, shod with cast iron, are mounted over it. The table is then revolved and sand and water fed onto the surface; the shoes revolve also, going over all parts of the plate and grinding it down to a true plane. Emery-powder is then fed on, in successive degrees of fineness until the plate is made absolutely smooth and all grit removed. After this, new rubbers, shod with very fine felt, are put on and liquid rouge is added for the polishing. When one side is completed the other side is similarly treated, the plate losing about 40% in weight by the operation."

Qualities of Polished Plate Glass. For glazing purposes there is but one quality of plate glass on the market. The best of this is selected for manufacturing mirrors. At one time, plate glass was extensively imported, but the gradually improving methods of the American manufacturers, as well as the great cheapening of the process, have practically eliminated imported plate glass from the market. The American plate glass is equal in every respect to that which was imported. The usual thickness of polished plate glass is from ¼ to 5/16 in, but it can be made thinner than this; and when required for residence-windows or car-windows, may be obtained in 3/16 or ⅛-in thicknesses. It is manufactured from the same thickness of rough plate used for the ordinary thicknesses, but is ground down thinner and, owing to the additional cost of grinding, as well as to the risk, is more expensive than glass of the ordinary thickness.

Cost* of Polished Plate Glass. The cost of plate glass of ordinary thickness varies with the size of the lights. The net price of polished plate glass (1913) glazing quality, was about 45 cts ($0.45) per sq ft, for sizes of not more than 10 sq ft per plate, 50 cts ($0.50) per sq ft for sizes containing from 10 to 50 sq ft per plate, and 65 cts ($0.65) per sq ft for sizes containing not more than 120 sq ft per plate. For larger sizes the price increased rapidly up to $2.00 per sq ft. The price, however, can be accurately determined only by means of a price-list and discount. The price-list in use (1913) was introduced in March, 1910, and the

* These are pre-war prices and the data are retained for purposes of comparison.

discount was about 90%. Plate glass 5/16 in thick costs 15% more than glass of the regular thickness on account of the extra expense of grinding it down. Plate glass 1/8 in thick costs from 25 to 40% more than glass of the regular thickness.

Sizes of Polished Plate Glass. Plate glass is cut into stock sizes, varying by even numbers from 6 by 6 in up to 144 by 240 in, or 138 by 260 in.

Comparative Cost of Different Kinds of Window-Glass. The following table gives an idea of the comparative cost of the different kinds and qualities of glass used in this country for glazing. The prices for the sizes are the 1914, net, average prices. The first column of the table gives the kinds of glass, and includes both the American plate and the American sheet glass. The other columns of the table give the sizes of the different lights in inches.

Comparative Cost of Different Kinds of Window Glass *

Kinds of glass	Sizes of lights in inches			
	24×32	30×36	36×40	48×60
American Plate Glass				
Glazing-quality	$2.35	$3.38	$4.60	$9.80
Crystal-sheet glass, 26-oz	1.00	1.54	2.34	6.66
American Sheet Glass				
Double-strength, first quality	0.54	0.83	1.25	3.55
Double-strength, second quality	0.47	0.73	1.13	3.30
Single-strength, first quality	0.37	0.56	......	......
Single-strength, second quality	0.32	0.50	......	......

It will be seen from this table that the relative difference in the cost of plate and sheet glass decreases rapidly as the sizes of the lights increase. The prices in this table are based on the list of October 1, 1903, on a discount of 90% for plate glass, 90 and 20% for American sheet glass and 85% on AA double-thick for 26-oz crystal-sheet glass.

Wire-Glass. This is described in Chapter XXIII, page 821.

Figured Rolled Glass. This is a translucent or OBSCURED glass with a pattern stamped on one surface. As the molten metal is rolled out on the table, the design, cut into the table, imprints itself into the soft glass. This kind of glass has almost entirely supplanted the ordinary ground glass because of its greater cleanliness. There are several popular designs on the market, made by various manufacturers. Some of the designs in common use are known as MOSS, MAZE, COLONIAL, FLORENTINE, COBWEB, etc. This glass is usually made 1/8 in thick and in large sheets from 24 to 42 in wide and from 8 to 10 ft long. MAZE, FLORENTINE and COBWEB designs can be had either with or without the wire mesh in them. One important property of figured rolled glass is that of diffusing the light which passes through it. (See, also, pages 1453 and 1554.)

Pressed Prism-Plate Glass.† This is manufactured in different patterns and for different purposes and includes (1) Imperial Prism-Plate Ornamental Glass in five different patterns, (2) Imperial Prism-Plate Glass and (3) Imperial Skylight Prism Glass. The general description is as follows:

* These are pre-war prices and the data are retained for purposes of comparison.
† Manufactured by the Pressed Prism Plate Glass Company, Chicago, Ill. See, also, pages 1453 to 1456.

(1) **Imperial Prism-Plate Ornamental Glass** is plate glass ground and polished on one side. It is manufactured in plates, 54 by 72 or 72 by 54 in, can be cut into smaller sizes, and is made in five different stock patterns. It is used in modern mercantile, office and public buildings for partitions, transoms, door-lights, vestibule doors, ornamental ceiling-lights, bank-windows and other street-windows, and in all places where semiobscurity and ornamental effect are desired. On account of its prismatic qualities it gives a strong diffusion of light for office-use where privacy is desired.

(2) Imperial Prism-Plate Glass. This is manufactured in large sheets, 54 by 72 or 72 by 54 in, and can be cut into smaller sizes. It is made in several different angles in order to obtain the proper diffusion of light for varying conditions. It is a plate glass, ground and polished on one side. There are no wires or bars to collect dirt and retard the light and it is very easily cleaned. It is used in the upper sashes of windows and in transoms, store-fronts, etc.

(3) Imperial Skylight Prism Glass. This is made in unit plates, 18 by 60 in, with a ½-in back, and conforms to the requirements of the Board of Fire Insurance Underwriters. It is used for skylights, roofs over areaways and in light-wells, etc. The possibility of leakage is lessened on account of the large-sized plates in which it may be obtained. These plates, however, can be cut into smaller sizes if required. It is particularly adapted for lighting the rear parts of stores and for railway-stations, sheds, etc.

Prism Glass, for glazing windows, skylights and sidewalk-lights, is now manufactured in a large number of forms in both prisms and sheets, and by several companies. The diffusing properties of several types are described on pages 1453 to 1456 under the subject of Illumination. This glass is made with sharp prisms which are glazed horizontally in the windows and by refracting the light throw it back horizontally into the rooms, adding very materially to the interior lighting. It is manufactured by several companies and can be procured from glass-jobbers in practically all the cities of the United States. (See, also, page 821.) Glass prisms for lighting are made of pieces of glass of standard dimensions, about 4 in square, with a smooth outer surface and an inner surface divided into a series of prisms. They are, in many cases, formed into plates by the process of electroglazing, the edges of the prism-lenses being welded together, so to speak, by a narrow line of copper which gives the desired stiffness and strength for use in large frames, and also an attractive appearance considered by some to be superior to ordinary leaded work. These prism-plates can be made in any desired size, but for very large surfaces two or more plates, divided by means of metal sash-bars, are generally used. (See, also, page 821.)

The commercial value of these prisms depends on that property of glass which causes what is known as REFRACTION. Prism-plates receive the light from the sky, not necessarily from the sun, and refract or turn it back into the room which is to be lighted. With an ordinary window the light from the sky, passing through the glass, strikes the floor at a point not very far distant from the window. As the color of the floor is usually dark, reflecting perhaps only one-tenth part of the light falling on it, the rear parts of the room receive only a small portion of the light which enters the window. For this reason it has been necessary to make very high stories for deep rooms, in order to light, even moderately, those parts which are at a distance from the window. When prisms are substituted for the common window-glass or plate glass, the rays of light as they enter the glass are refracted, and by employing prisms of the proper angle, the rays may be given almost any direction. Moreover, by utilizing different prisms in the same plate, some of the rays may be directed to the rear of the room while others are thrown so as to strike near the front. The prism-plates do not increase

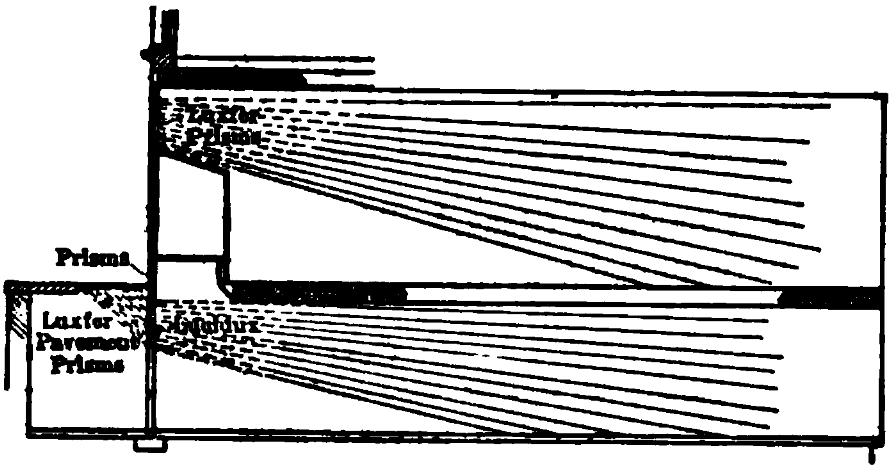
uantity of light entering the window, but simply redistribute it, directing it nto those portions of the room in which it is most needed. By thus changing he direction of light-rays a room with a low ceiling can be better lighted than vhen sheet or plate glass is used. To insure success in the lighting of interiors y means of prisms requires, however, a superior quality of glass, and careful cientific calculations and experiments, besides practical and attractive means f glazing and methods of installation. These requirements have been met by he several companies making these prisms and their products may be considered among the relatively new building materials. They have been very uccessfully applied to the lighting of dark rooms by daylight. The application f prisms to any particular building depends upon the surrounding conditions nd requirements, each case requiring some special treatment; but in a general ay the various appliances used in the installations may be divided into four asses as follows:

(1) Vertical Plates, which are set directly in the sashes in place of the ordinary indow-glass. They are commonly used for the transom-lights of store-windows d the upper sashes of double-hung windows. They may also fill the entire indow.

(2) Foriluxes, which are vertical prism-plates set in independent frames and aced in window-openings substantially flush with the face of the wall.

(3) Canopies, which are external prism-plates in independent frames, placed er window-openings and set at an angle with the vertical, a position similar to at of an ordinary awning.

(4) Pavement-Prisms, which are set in iron frames in the pavements or sidelks, in place of the ordinary bull's-eye lights. In connection with the pavement-prisms, when a ll-lighted basement is sired, vertical plates of isms, hung below and posite the pavementhts, are often used. ese hanging, vertical tes receive the light m the pavementsms, and again changits direction, project horizontally into the ement. This feature illustrated in the



Refraction and Transmission of Light by Prisms

ure here given, reproduced through the courtesy of the Luxfer Prism mpany.

The canopies may be made either stationary or adjustable and may be emyed in a variety of ways, combining the useful with the ornamental. The ging, vertical plates lend themselves to a highly decorative treatment. In h the fixed and hanging vertical plates the prisms may be arranged to proe ornamental effects, and designs may be inwrought on the face of the prismtes to correspond with the designs worked into the surfaces of the building with the style of the entire façade. The prism-plates weigh no more, and n less, than plate glass of the same size, while they are much stronger in sting wind-pressure, the action of hail and the impact of flying fragments. ough transmitting a very large amount of light, these prism-plates are not sparent in the ordinary sense, and may thus be used as screens to hide unactive views or to prevent persons looking either in or out of a window. At

the same time a maximum quantity of light is admitted. The prism-pl[ates] owing to the stiff, durable manner in which they are united by the elect[ro-] glazing process, serve, also, as a fire-retardant or as a partial substitute for [the] ordinary iron fire-shutters. The copper glazing forms, as it were, a contin[uous] rivet, which holds the individual prism-lights together, even after they h[ave] become badly cracked by the action of fire and water. The details of the va[ri-] ous makes of prisms are too complicated to be set forth in a few pages, but th[ey] are well described in the various handbooks and catalogues published by [the] different manufacturers. From a commercial point of view the special a[d-] vantages of these systems of interior lighting are manifold. They transf[orm] rooms, particularly basements, otherwise too dark for occupancy, into inco[me-] producing spaces; in many buildings they do away with the use of light-sha[fts,] thus saving a large amount of valuable floor-space; and in all large or de[ep] rooms they effect a great saving in artificial lighting. Once installed, the[re is] no cost for maintenance. The extent to which these prisms have been used b[y] architects, in both new and old buildings, shows that they have had a deci[ded] influence upon commercial architecture.

Glass for Skylights. General Description. The glass ordinarily used n[ow] for skylights is either rough or ribbed skylight-glass, and since the great cheap[en-] ing in the process of manufacturing glass with wire mesh in it, wire-glass, also, [is] being largely used for this purpose. The sizes used depend largely upon t[he] pitch of the skylight, small sizes being more desirable when the pitch is sl[ight.] The weight of rough or ribbed glass, with or without wire mesh, is approximat[ely] as follows:

Weight of Rough or Ribbed Glass

Thickness in inches........	1/8	3/16	1/4	3/8	1/2	5/8	3/4	1
Weight in pounds..........	2	2½	3½	5	7	8½	10	[illegible]

Cost of Skylight-Glass.* The different kinds of skylight-glass in small qua[n-] tities were quoted (1914) about as follows:

Cost of Skylight-Glass

Kinds of glass	Cost
Rough or ribbed skylight-glass, 1/8-in..............................	6 cts per sq[.]
Rough or ribbed skylight-glass, 3/16-in..............................	8 cts per sq[.]
Rough or ribbed skylight-glass, 1/4-in..............................	12 cts per sq[.]
Rough or ribbed wire-glass, 1/4-in..............................	16 cts per sq[.]
Maze, Cobweb, or Florentine wire-glass..............................	20 cts per sq[.]
Sheet prism glass..............................	20 cts per sq[.]

Glass for Mirrors. Mirrors are made by silvering one side of a shee[t of] polished plate glass. This is the only kind of glass suitable for making mirr[ors] because, unless the surface of glass is polished, the reflection is distorted. [A] generation ago, mirrors were made by the old-style process of pressing the g[lass] by means of heavy weights onto mercury, backed by tinfoil, the affinity of [mer-] cury for tin forming an amalgam which protected the back of the mirrors [and] gave the reflection. This was a very slow and expensive process. During [the] twenty-five years prior to 1913, practically all of the mirrors made [were] manufactured by what is known as the PATENT-BACK process, in which [...]

* The prices have materially advanced and as they change from year to year, the m[an-]ufacturers' lists must be consulted.

silver is precipitated in a film over the surface of the glass, thus giving it the operty of reflecting. This film is afterward covered and protected by shellac, rnish and paint. This modern method of manufacture has made it possible supply mirrors in considerably less time, and at a very much lower cost, than hen manufactured by the old-fashioned MERCURY-BACK process. There are any who claim that in spite of modern processes of manufacture, the old ethod produced the best results as far as durability is concerned. This is idenced by the following statement inserted by Mr. Kidder in the preceding ltions of the Pocket-Book: "There are two kinds of mirrors on the market, e the old time reliable mercury-back mirror, the other the nitrate of silver, or at is better known to the trade as the patent-back mirror. The latter is now d has, in recent years, been most extensively sold as a substitute for the former. the manufacture of mercury-back mirrors no chemicals are used, only two tals, mercury and tin-foil. The affinity of mercury for tin forms an amalgam pervious to and not affected by the atmosphere. A mercury-back mirror is iversally considered to be the only durable and permanent mirror. A nitrate-silver or patent-back mirror is produced by the precipitation of a chemical ution of nitrate of silver and other media on the surface of the glass, to which added one coat of shellac varnish overlaid with one or more coats of paint. is mirror, irrespective of the quality of the glass from which it is made, will adily deteriorate from the date of its manufacture to that of its final collapse, ich may occur at any time from a few months, but certainly within a few rs."

MEMORANDA ON ROOFING

Shingles.* The best shingles are those made from cypress, cedar, redwood, ite and yellow pine and spruce, in the order mentioned. Redwood, while haps not quite as durable as cypress, is less inflammable; sawed pine shingles inferior to cedar, and spruce shingles are not suitable for good work.

Number and Weight of Cedar and Pine Shingles Per Square of One Hundred Square Feet

ngth, in	Assumed width, in	Weather or gauge, in	Number of shingles per square †	Weight per square		Number of nails per square	Weight of nails per square, lb
				Cedar, lb	Pine, lb		
14	4	4	900	210	233	1 800	4.50
15	4	4½	800	200	222	1 600	4.00
16	4	5	720	192	213	1 440	3.60
18	4	5½	655	197	218	1 310	3.28
20	4	6	600	200	222	1 200	3.00

24	4	7	515	206	229	1 030	2.58

izes of Shingles. Cedar and redwood shingles as commonly sawed are 20 in ngth, and cypress shingles usually from 20 to 24 in long, the longer ones allow-

* For more complete information see Kidder's Building Construction and Superintene, Part II, Carpenters' Work, pages 321 to 325.

† To allow for waste, add from 6 to 10%, the greater allowance being for the shorter les.

ing a greater exposure to the weather. Redwood shingles and the cedar shin from the States of Washington and Oregon, which States furnish most of shingles used west of the Mississippi, are 5/16 and 9/16 in thick at the b cypress shingles are usually sawed thicker. Those used in Boston are 3/16 thick. Ordinary roofing-shingles are of random widths, varying from 2½ 14 and sometimes 16 in. They are put up in bundles, usually four bundles the thousand. A THOUSAND common shingles means the equivalent of 1 0 shingles 4 in wide.

Dimension-Shingles are sawed to uniform width, either 4, 5, or 6 in. Dim sion-shingles with the butt sawed to various patterns are also carried stock.

On hip-roofs, or for four valleys, add 5% for cutting. On irregular roofs wi dormer-windows, add 10%. It is claimed that redwood shingles will go farth than cedar shingles. With a rise to the roof of from 8 to 10 in to the foot, ced shingles, or any shingles 16 or 18 in in length, should be laid from 4 to 4¼ in the weather; with a rise from 10 to 12 in, from 4¼ to 4⅜ in to the weath and on steeper roofs they may be laid from 4½ to 5 in. Redwood shingles m be laid ½ in more to the weather. Some authorities allow slightly greater e posures for these lengths. Where the longer shingles are used the exposure the weather may be increased up to 7 in for the 24-in lengths. On walls ced shingles are commonly laid 5 in to the weather, and redwood shingles 6 in.

Labor. An average shingler should lay 1 500 shingles in 9 hours on pl work; on irregular roofs with dormers, 1 000 per 9 hours.

Nails. It requires from 3½ to 4½ lb of threepenny or from 3½ to 6½ lb o fourpenny nails to 1 000 shingles, depending upon width and length of shingles.

Slate Roofs

Characteristics of Good Slate. A good slate should be both hard and toug If the slate is too soft, however, the nail-holes will become enlarged and the sla will become loose. If it is too brittle the slate will fly to pieces in the process squaring and holing and will be easily broken on the roof. "A good slate shoul give out a sharp metallic ring when struck with the knuckles; should not split under the slater's axe; should be easily HOLED without danger of fracture, a should not be tender or friable at the edges." The surface when freshly spl should have a bright metallic luster and be free from all loose flakes or dull s faces. Very few of the Vermont slates, however, have the metallic luster ribbons. Most slates contain ribbons or seams which traverse the slate approximately parallel directions. Slates containing soft ribbons are inferi and should not be used in good work.

Color. The color of slates varies from dark blue, bluish black, and purple gray and green. There are also a few quarries of red slate. The color of the slate does not appear to indicate the quality. All slate quarried in Maine black as is also that quarried in Virginia, while that quarried in Pennsylv and Maryland is also black but borders on dark blue and is advertised by firms as dark blue. Slate quarried in New York State is red, of various while that quarried in Vermont is of various colors, such as green, purple, v gated, etc. The red and dark colors were formerly considered the most tive but at the present time the greens are going on some of the largest finest of the new residences. Some slates are marked with bands or pa of a different color, and the dark-purple slates often have large spots of green on them. These spots do not as a rule affect the durability of the but they greatly detract from its appearance.

Grading of Slates. The Monson, Me., slates and Brownville, Me., slates re graded as follows: No. 1. Every sheet to be full 3/16 in thick, both ides smooth and all corners full and square. No pieces to be winding or varped.

No. 2. Thickness may vary from 1/8 to 1/4 in, all corners square, one side generlly smooth, one side generally rough, no badly warped slates.

The Bangor, Pa., slates are graded:

No. 1 Clear. A pure slate without any faults or blemishes.

No. 1 Ribbon. As well made as No. 1 Clear, except that it contains one or ore RIBBONS (a black band or streak across the slate), which, however, are high nough on the slate to be covered when laid, thus presenting a No. 1 roof.

No. 2 Ribbon. This contains several RIBBONS, some of which cannot be overed when laid.

No. 2 Clear. A slate without RIBBONS, made from rough beds.

Hard Beds. A clear Bangor slate, not quite as smooth as No. 1 Clear, but uch better than No. 2 Clear.

Ordinary Bent Slate. A smooth slate similar to No. 1 Clear, but bent at a dius of about 12 ft.

Punching. Formerly nail-holes in slates were punched on the job; now, hower, slates are bored and countersunk at the quarry, when so ordered. Architts should always specify that the slates are to be bored and countersunk, as inching badly damages the slates.

Sizes. The sizes of slates range from 9 by 7 in to 24 by 14 in, there being some irty-seven different sizes; the more common sizes, however, are the following: e sizes of slates best adapted for plain roofs are the large wide slates, such as by 16 in, 18 by 12 in, 20 by 12 in, or 24 by 14 in. Slates from 8 by 16 to 10 20 in are popular sizes, 9 by 18-in slates being probably used oftener than ose of any other size. The 11 by 22 and 12 by 24-in slates are used principally very large high buildings. The lower grades of slate are used largely on wareuses and barns. The larger sizes make fewer joints in the roof, require fewer ils, and diminish the number of small pieces at hips and valleys. For roofs t up into small sections the smaller sizes, such as 14 by 7 in or 16 by 8 in, look e best.

Thickness. Slates vary in thickness from 1/8 to 3/8 in; 3/16 in is the usual thicks for ordinary sizes (see Grading of Slates in the preceding paragraphs). It of utmost importance for architects to specify the thickness of slates, either ly 3/16 in thick, or fully 1/4 in thick, to secure a strong and durable roof.

Laying. Slates are laid either on a board sheathing (rough, or tongued and ooved) covered with tarred or water-proof paper or felt, or on roofing-laths m 2 to 3 in wide and from 1 to 1 1/4 in thick, nailed to the rafters at distances art to suit the gauge of the slates. Each slate should lap the slate in the ond course below, 3 in. The slates are fastened with two threepenny or fourny nails, one near each upper corner. For slates 20 by 10 in or larger, fourny nails should be used. Copper, composition, tinned, or galvanized nails uld be used. Plain-iron nails are speedily weakened by rust, and they ak and allow the slates to be blown off. On iron roofs slates are often ced directly on small iron purlins spaced at suitable distances apart to receive m, and fastened with wire or special forms of fasteners. THE GAUGE of a te is the portion exposed to the weather, which should be one-half the reinder obtained by subtracting 3 in from the length of the slate. Roofs to be ered with slate should have a rise of not less than 6 in to the foot for 20-in or in slates, or 8 in for smaller sizes.

Elastic Cement. In first-class work, the top course of slate on the ridge, a slate for from 2 to 4 ft from all gutters and 1 ft each way from all valleys a hips, should be bedded in elastic cement.

Flashings. By FLASHINGS are meant pieces of tin, zinc, or copper laid slate and up against walls, chimneys, copings, etc.

Counterflashings are of lead or zinc, and are laid between the courses in bri and turned down over the flashings. In flashing against stonework, grooves reglets often have to be cut to receive the counterflashings.

Close and Open Valleys. A close valley is one in which the slates are mite and flashed in each course and laid in cement. In such valleys no metal can seen. Close valleys should only be used for pitches above 45°. An open val is one formed of sheets of copper or zinc 15 or 16 in wide, over which t slates are laid.

Old English Method of Laying Slates.* This method of laying slate i volves the use of different shades of colored slates in graduated courses a random widths beginning at the eaves, for example, with slates 28 in long and 1 in thick, and using the different thicknesses from 1¼ to ⅜ in, in shorter length in working upward on the roof. The use of this kind of work for roofs has i creased in recent years and the method possesses vast possibilities for car ing out architects' ideas for varied artistic effects. The slates are made wi rough-cut edges in all thicknesses from 3/16 to 1½ in, in a combination of vari shades carefully selected in such proportion as to produce the best possible h mony, when laid. As all of these colors and shades are unfading, the WEATHE effect is obtained at once and is permanent. These slates are made not only i usual sizes, but in the OLD-ENGLISH STYLE, to be laid in graduated courses of d ferent lengths and in random widths. The Old English color-combination ro ing-slates should be specified to secure the light-and-shadow effect, and it is of t utmost importance to specify the thickness desired, as the price is the same f all sizes, while the cost varies according to thickness. When graduated cour are desired, specifications should call for the number of courses to be laid in ea length and thickness beginning at the eaves-courses, where the thickest sla are used in the largest sizes, sometimes 30 or even 36 in in length, and worki upward on the roof with the shorter lengths and thinner slates to the ridges wh the smallest sizes and thinnest slates are used. To secure a rough effect at mi mum cost, specifications should call for Old English color-combination, all sla to be fully ¼ in thick with rough cut edges and graduated courses in sizes ra ing from 24 by 16 to 12 by 6 in, with nail-holes drilled and countersunk. T secure the best rough effect, specifications should call for eaves-courses not le than ¾ in thick, stating the thickness desired for the eaves, and the number courses desired in each length and thickness. Among the good specimens of t Old English style of roofing may be mentioned the buildings of Princeton U versity for the Graduate College, where different shades of unfading-gr slates are used in thicknesses running from 1¼ in at the eaves to ⅜ in at t ridge.

Measurement. Slates are sold by the SQUARE, by which is meant a suffici number of slates of any size to cover 100 sq ft of surface on a roof, with 3 in lap, over the head of those in the second course below. The square is also t basis on which the cost of laying is measured. "Eaves, hips, valleys, and c tings against walls or dormers are measured extra; 1 ft wide by their wh

* Full information in regard to the details of the slates for this purpose and the meth employed in laying them can be obtained from the various companies.

ngth, the extra charge being made for waste material and the increased labor quired in cutting and fitting. Openings less than 3 sq ft are not deducted, and ll cuttings around them are measured extra. Extra charges are also made for orders, figures, and any change of color of the work and for steeples, towers, and erpendicular surfaces."*

Cost.† The cost of slates varies with the size, color and quality. The prices iven in the following table were about the average in 1915 for blue-black slate, of o. 1 grade, loaded on the cars at the Pennsylvania quarry. The freight in ır-load lots of 60 squares or over to Philadelphia from Bethlehem, Pa., was 60 s per square, from Pennsylvania to Omaha, Neb., $2.60 and from Vermont, oout the same. It will be seen that slates of the MEDIUM sizes cost the most, id those of the larger and smaller sizes the least. Special prices are quoted for ecial sizes. The larger sizes make the cheapest roofs. Red slates cost from to 150% more than black slates. The green slates are more expensive than e black with the exception of the Maine and Peach Bottom varieties.

Number and Cost † of Slates, and Pounds of Nails to 100 Square Feet of Roof

3-inch Lap

Sizes of slates, in	Exposed when laid, in	Number to a square	Weights of galvanized nails, lb	oz	Cost per square at quarry

foot of Vermont slate weighs approximately 175 lb. The average shipping weight for No. 1, 3/16-in slates, is approximately 725 lb; for 1/4-in slates, 1 000 lb; for 1/2-in slates, 2 000 lb, etc.

Roofing-Tiles

General Notes on Roofing-Tiles. The term ROOFING-TILE is commonly understood to refer to exterior roof-covering made from clay in units of various shapes and laid with overlapping edges. Clay or terra-cotta roof-tiles have long been very largely used in Europe, where their cost is much less than in America. Since the year 1893 the advance here in the character and extent of roofing-tile has been marked and rapid. This material can now be had at much lower prices than formerly prevailed, and the result has been that thousands of squares of terra-cotta tiles have been placed on shops and factories which would under former conditions have been covered with slate or metal. Whether or not a tile roof is as durable and satisfactory as one of No. 1 slate is a much-disputed question. Mr. Kidder was of the opinion that, considering the quantities used, slates have given better satisfaction than tiles. A tile roof, however, is certainly more attractive than a slate roof, and it is generally held that there are many roofing-tiles on the market which if properly laid prove as tight and durable as slates. There are so many patterns of roofing-tiles that it is impossible here to enter into a description of them. Of the various patterns, those which interlock are considered from a practical standpoint, to make the most satisfactory roof.

Laying Roofing-Tiles. Roofing-tiles have been laid directly on a porous book tile or concrete base or on a sheathed surface over such base, or they have been fastened to stripping over the sheathing or wooden or steel purlins by means of copper wires. When thus fastened by wires, the joints were usually pointed on the under side after they were laid, to prevent the entrance of dust or dry snow. Tiles of the older patterns were nailed to the sheathing, but later on this method was superseded by the practice of fastening with copper wires from pierced lugs near the lower ends of the tiles. The best modern method, however, seems to be the one involving a solid continuous base for the roofing-tiles, whether or not purlins are used. "Such purlins should be filled in between either with book tiles or a concrete base and felt should be laid thereon. The book tiles, if used, should be of a porous quality. Instead of regarding the nailing of tiles as a defective method, we have returned to it as the only proper method of fastening tiles and have eliminated the stripping of sheathed roofs and the use of copper wires. Such methods would do in some portions of central Europe where the winds and other climatic conditions are not severe, but through a twenty-five years' experience in the varied climatic conditions of the United States, we have found that the nailing of tiles with copper nails is the only satisfactory method of application. We have also found that a roof should be sheathed and covered with a good asphaltum-felt to prevent wind-suction." * Roofing-tiles weigh from 750 to 1 200 lb per square of 100 sq ft.

Specifications for Tile Roofing

The following specification † contains valuable suggestions for the proper laying of tile roofs:

All pitched roofs shall be covered with (——) tiles with fittings suitable for

* Quoted by permission from data on roof-tiling, by the Ludowici-Celadon Company, Chicago, Ill.

† Prepared from data furnished by the Ludowici-Celedon Company, Chicago, Ill.

each pattern unless otherwise selected by the architect. The tiles as specified above are to be hard-burned, of red color, and in accordance with samples deposited in the office of the architect.

(1) Preparation of Roof. Before the roofer is sent for, the owner or general contractor is to construct the roofs in strict accordance with the plans, sheath the roofs TIGHT, have all chimneys and walls above the roof-line completed, have all vent-pipes put through the roofs, furnish all strips of required width used under hip-rolls, furnish all 1 by ⅞-in cant-strips used under the tiles at the eaves and have all the scaffolding ready for the roofers' use. The metal-contractor is to have all gutters in place on the roof (gutters, whether box, hanging or secret gutters, are to extend over the roof-sheathing and cant-strips, and run under the felt and tiles at least 8 in) and is to have in place, also, all valley-metal, the width of which is to be not less than 24 in, with both edges turned up ¼ in through the entire length of the valley. The valley-metal is to be fastened with clips and never nailed or punctured in any manner. The valley-metal is to be laid over one layer of felt running lengthwise the entire distance of the valley. The metal-contractor is to have in readiness all flashing-metal used alongside and in front of dormers, gables, skylights, towers and perpendicular walls, and around vent-pipes and chimneys, and is to place the same after the arrival of the tile-roofer and under his direction.

(2) Laying the Felt. After the roofs have thus been prepared to receive the felt and tiles, the tile-roofer is to cover the sheathing of the roofs with one thickness of asphalt roofing-felt weighing not less than 30 lb to the square, laying the same with a 2½-in lap and securing it in place by capped nails. The felt is to be laid parallel with the eaves, lapped over all valley-metal about 4 in and laid under all flashing-metal about 6 in.

(3) Laying the Tiles. The roof having thus been prepared, the tile-layer is to fasten the tiles with copper nails. The roofer is to see that the tiles are well locked together and that they lie smoothly, and no attempt is to be made to stretch the courses. The tiles are to be laid so that the vertical lines are parallel with each other and at right-angles to the eaves. The tiles that verge along the hips are to be cut close against the hip-boards, and a water-tight joint made by cementing cut hip-tiles to the hip-boards with elastic cement. Each piece of hip-roll is then to be nailed to the hip-board, and the hip-rolls are to be cemented where they lap each other. The interior spaces of hip-rolls and ridge-rolls are not to be filled with the pointing-material.

Cost of Roofing-Tiles.* The prices of tiles vary from $7 to $30 per square, according to the character of the surface-finish and to the pattern. The cost of laying, including asphalt-felt, varies from $5 to $10 per square, according to the pattern of tiles used, the number of layers of felt and the character and extent of the roof. If roofing-tiles are laid on book tiles or on cement, 20% must be added to the cost for laying on wooden sheathing. Fluctuating values of copper make the item of copper nails, when these are used, one of importance.

Sheet-Metal Tiles. Roofing-tiles stamped from sheet steel, plain or galvanized, and also from sheet copper, in imitation of clay tiles, are made by several manufacturers and have been extensively used for factories and buildings of secondary importance. The first cost of these tiles, except those made of copper, is much less than that of clay tiles and they do not require as heavy roof-framing. Tin or galvanized-iron tiles, however, must be painted every few years, so that for a long period of years they probably cost as much as clay tiles and more than slate.

* These prices have advanced and the manufacturers' lists must be consulted.

Tin Roofs

The Sheets. Roofing-plates are made of soft steel of various special analyses or wrought iron (more commonly of the former), covered with a mixture of lead and tin, and are designated TERNE-PLATES, in distinction from plates coated only with tin and therefore called BRIGHT TIN. Roofing-plates are coated by two methods. (1) The original method of coating the plates consisted in dipping the black plates by hand into the mixture of tin and lead, and allowing the sheets to absorb all the coating that was possible; and at least one brand of roofing-tin is still made by this process. (2) The other process, by which the majority of roofing-plates are now made, is known as the PATENT-ROLLER-PROCESS, by which the plates are put into a bath of tin and lead, and are passed through rolls. The pressure of these rolls leaves on the iron or steel a thickness of coating which, to a great extent, determines the value of the plates. These rolls can be adjusted to leave a relatively large amount of coating on the plate, an ordinary coating, or a very scant coating. The heavier the coating the more valuable the plate. Some makers employ a variation of this patent process, by which the plates are given an extra dip, by hand, in an open pot, to give a HAND-DIPPED FINISH. It is claimed that hand-dipped plates will last much longer than those made by the new process, although the latter process is much more extensively used and many good roofing-sheets are made by it.

Brands. The best roofing-plates always have the BRAND stamped on them, and as the manufacturers have a pecuniary interest in keeping up the reputation of these brands, the only way of being sure of a good tin roof is to specify a brand of tin that has a reputation for quality and durability. Some of the best-known brands are Taylor's Target-and-Arrow (formerly Old Style); Merchant's Old Method, MF; Follansbee's Banfield Process; and Margaret. Machine-made plates are usually stamped with the weight of coating per box of 112 sheets, 28 by 20-in size.

Sizes of Sheets. The common sizes of tin plates are 10 by 14 in and multiples of that measure. The sizes generally used are 14 by 20 in and 28 by 20 in. The larger size is the more economical to lay, and hence roofers prefer to use it; but for flat roofs the 14 by 20-in size makes the better roof.

Thicknesses of Sheets. Terne-plates are made in two thicknesses, IC, in which the iron body weighs about 50 lb per 100 sq ft, and IX, in which it weighs 62½ lb per 100 sq ft. For roofing, the IC, or lighter weight, is to be preferred, because the seams do not contract and expand as much as they do when the thicker plates are used. For spouts, valleys and gutters, however, IX plates should always be specified, and should preferably be used for flashings, as they are stiffer and less liable to be dented or punched. The thickness of the iron does not add to the durability of the plates, as this depends entirely upon the tin coating.

Weights of Sheets. The standard weight of 14 by 20-in IC terne-plates is 107 lb for 112 sheets, the number usually packed in one box, and of 14 by 20-in IX sheets, 135 lb. The 28 by 20-in sheets should weigh just twice as much. The black sheets, before coating, should weigh, per 112 sheets, from 95 to 100 lb for IC, 14 by 20-in sheets, and from 125 to 130 lb for IX, 14 by 20-in sheets. The difference between the weights of the black sheets and finished sheets is the weight of the tin. A heavily coated tin should weigh from 115 to 120 lb per 112 sheets for IC, 14 by 20-in sheets, and from 145 to 150 lb for IX, 14 by 20-in sheets. The 28 by 20-in sheets should, of course, weigh twice as much.

The Roof. Roofs of less than one-third pitch are made with FLAT SEAMS and should preferably be covered with 14 by 20-in sheets rather than with 28 by 20-in

sheets, because the larger number of seams stiffens the surface and helps to prevent buckles and rattling in stormy weather. For a flat-seam roof, the edges of the sheets are turned ½ in, locked together and well soaked with solder. The sheets are fastened to the sheathing-boards by cleats spaced 8 in apart and locked in the seams. Two 1-in barbed and tinned-wire nails are used in each cleat. No nails should be driven through the sheets. The seams must be made with great care and sufficient time taken to properly SWEAT the solder into the seams. Steep tin roofs should be made with STANDING SEAMS and with 28 by 20-in sheets. The sheets are first single-seamed or double-seamed and usually soldered together, preferably end to end, into long strips that reach from eaves to ridge. The sloping seams are composed of two UPSTANDS, interlocked at the upper edge, and held to the sheathing-boards by cleats. The standing seams are usually not soldered but simply locked together with the cleats folded in about 1 ft apart. Nails should be driven into the cleats only. The use of acid in soldering the seams of a tin roof should be carefully avoided as acid coming in contact with the bare iron on the cut edges and corners, where the sheets are folded and seamed together, causes rusting. No other soldering-flux but good rosin should ever be used.

Durability of Tin Roofs. A tin roof of good material, properly put on, and kept properly painted, will last from forty to fifty years, or longer. All traces of rosin left on the roof should be removed as soon as the tin is laid and soldered, and one coat of paint should be applied promptly; a second coat should follow two weeks after the first. One or more layers of felt or water-proof paper should be placed under the tin, to serve as a cushion, and also to deaden the noise produced by rain striking the tin. The durability of tin roofing, and especially of tin gutters, valleys and flashings, is generally increased by painting the tin on the back before laying. An excellent paint for tin roofs is composed of 10 lb of Venetian red, 1 lb of red lead and 1 gal of pure linseed-oil.

Maintenance of Tin Roofs. The tin roof should be given one coat of paint after it is laid and an additional coat of paint at four-year or five-year intervals should be amply sufficient to keep its upper surface in first-class condition as long as the building stands. With each painting the roof is fully restored to its original condition. Graphite and tar paints should be avoided on tin roofs. Metallic brown, Venetian red, red oxide or red lead, only, should be used as pigments, with pure linseed-oil. Tinned gutters should be swept clear of accumulations of leaves, dirt, etc., and if water has a tendency to lie in the gutters they should be painted yearly.

Number of Sheets Required to a Square. For FLAT-SEAM ROOFING a sheet of tin 14 by 20 in, with ½-in edges, measures, when edged or folded, 13 by 19 in, or 247 sq in; but its covering capacity when joined to other sheets on the roof is only 12½ by 18½ in, or 231.25 sq in. The number of sheets to a square, therefore, equals 14 400 divided by 231.25 or 63, and an area of 1 000 sq ft requires 625 sheets. A box of 112 14 by 20-in sheets will cover, approximately, 180 sq ft. Sheets 28 by 20 in, when edged or folded, have a covering capacity of 490.25 sq in each. To cover 1 000 sq ft (10 squares) requires 294 sheets. For STANDING-SEAM ROOFING the locks require 2¾ in off the width and 1⅛ in off the length of the sheet. A 28 by 20-in sheet, with the seams on the long edges, will cover 463 sq in. To cover 1 000 sq ft requires 312 sheets.

The Cost* of Tin Roofing varies from $8 to $12 per square, according to the grade of the tin, the locality and nature of the work and the scale of wages. Standing-seam roofs cost about 50 cts a square less than flat-seam roofs. The cost, when 14 by 20-in sheets are used, is about 25% more than for 28 by 20-in

* Variations in cost must be ascertained from manufacturers' lists.

sheets, owing to the greater number of seams; hence, more tin, solder, cleats and work are required.

How a Tin Roof Should be Laid *

The Slope of the Roof. If the tin is laid with a flat seam or flat lock, the roof should have an incline of ½ in or more to 1 ft. If laid with a standing seam, there should be an incline of not less than 2 in to 1 ft. Although tin is used on roofs of less pitch than this and on some which are almost flat, a good pitch is desirable to prevent the accumulation of water and dirt in shallow puddles. Gutters, valleys, etc., should have sufficient incline to prevent water from standing in them or backing up far enough to reach standing seams. Tongued and grooved sheathing-boards of well-seasoned dry lumber are recommended. Narrow widths are preferable, and the boards should be free from holes, and of even thickness. A new tin roof should never be laid over old tin, rotten shingles, or tar roofs. Sheathing-paper is not necessary where the boards are laid as specified above. If steam, fumes, or gases are likely to reach the under side of the tin, some good water-proof sheathing-paper should be used. Tarred paper should never be used. No nails should be driven through the sheets.

Flat-Seam Tin Roofing. When the sheets are laid singly, they should be fastened to the sheathing-boards by cleats, using three to each sheet, two on the long side and one on the short side. Two 1-in barbed-wire† nails should be used to each cleat. If the tin is put on in rolls the sheets should be made up into long lengths in the shop, and the cross-seams locked together and well soaked with solder. They should be edged ½ in, and fastened to the roof with cleats spaced 8 in apart, and the cleats locked into the seam and fastened to the roof with two 1-in barbed-wire nails to each cleat.

Standing-Seam Tin Roofing. The sheets should be put together in long lengths in the shop, and the cross-seams locked together and well soaked with solder. They should be applied to the roof the narrow way, and fastened with cleats spaced 1 ft apart. One edge of the course is turned up 1¼ in at a right angle, and the cleats are installed. The adjoining edge of the next course is turned up 1½ in, and these edges are locked, turned over and the seam flattened to a rounded edge.

Valleys and Gutters. These should be lined with IX tin, and formed with flat seams, the sheets being applied the narrow way. It is important to see that good solder, bearing the manufacturer's name, is used, that it is guaranteed one-half tin and one-half lead, new metals, and that nothing but rosin is used as a flux. The solder should be well sweated into all seams and joints.

Painting. All painting should be done by the roofer. The tin should be painted one coat on the under side before it is applied to the roof. The upper surface of the tin roof should be carefully cleaned of all rosin-spots, dirt, etc., and immediately painted. The approved paints are metallic brown, Venetian red, red oxide, and red lead, mixed with pure linseed-oil. No patent drier or turpentine should be used. All coats of paint should be applied with a hand-brush and well rubbed on. A second coat should be applied two weeks after the first and a third coat one year later.

Caution. No unnecessary walking over the tin roof, or use of it for storage of materials, should be allowed at any time. Workmen should wear rubber-soled

* These suggestions are in accordance with the standard working specifications adopted by the National Association of Sheet Metal Contractors.

† The effect of barbing on the holding power of nails is a disputed question.

bes or overshoes when on the roof. Wherever the slope is steep enough the tin ould be laid with standing seams, which allow for expansion and contraction.

Sizes, Weights, Etc., of Roofing-Tin *

Roofing-tin is usually furnished in two sizes, sheets 14 by 20 in and 28 by 20 in, cked 112 sheets to the box. Target-and-Arrow tin is furnished in three thick-ses: IC thickness, approximately No. 30 gauge, U. S. Standard; IX thickness, proximately No. 28 gauge, U. S. Standard; 2X thickness, approximately No. gauge, U. S. Standard, etc. Weight per 100 sq ft laid on the roof, about 65 lb r IC thickness.

Covering Capacity of Roofing-Tin

lat-Seam Tin Roofing. The following table shows the quantity of 14 by 20-in required to cover a given number of square feet with flat-seam tin roofing. A et 14 by 20 in with ½ in edges measures, when edged or folded, 13 by 19, 247 sq in, but its covering capacity when joined to other sheets on the roof nly 12½ by 18½ in, or 231.25 sq in. In the following table each fractional t of a sheet is counted a full sheet.

o. of square feet	100	110	120	130	140	150	160	170	180	190	200

A box of 112 sheets 28 by 20 in laid in this way will cover 360 sq ft.

aying the Long or Short Way. Sheets 14 by 20 in can be laid either the or short way. The best roof is made by laying the sheets the 14-in way; ilarly, in using the 28 by 20-in sheets, they should always be laid the 20-in , that is, with the short dimension crosswise.

Cost of Roofing-Tin

Cost of Tin for Standing-Seam Roofing

Sheets 28 by 20 in. Price per box and per square foot

hen tin costs per box......	$11.00	$11.50	$12.00	$12.50	$13.00	$13.50	$14.00	$14.50	$15.00	$15.50
anding-seam roofing costs per sq ft.....	0.0297	0.0310	0.0324	0.0337	0.0351	0.0364	0.0378	0.0391	0.0404	0.0418
hen tin costs per box......	16.00	16.50	17.00	17.50	18.00	18.50	19.00	19.50	20.00	20.50
anding-seam roofing costs per sq ft.....	0.0432	0.0446	0.0459	0.0473	0.0486	0.0500	0.0513	0.0526	0.0540	0.0553
ien tin costs per box......	21.00	21.50	22.00	22.50	23.00	23.50	24.00	24.50	25.00	....
anding-seam roofing costs per sq ft.....	0.0567	0.0580	0.0594	0.0607	0.0621	0.0634	0.0648	0.0661	0.0675	....

e above estimates do not include cost of laying. The cost, using 14 by 20-in sheets, amount to about 25% more than the cost, using 28 by 20-in sheets, owing to the er number of seams. More tin, solder, cleats and work are therefore necessary.

Tin in Rolls, or Gutter-Strips

Tin in Rolls. For the convenience of roofers and for rush-orders, Target-and-rrow tin is put up in rolls 14, 20 and 28 in wide. Each roll contains 108 sq ft ibout 63 lin ft, 28 by 20-in sheets laid 20 in wide). The tin is painted on one : both sides, as wanted, with an approved metallic brown paint. The seams e carefully soldered by hand, good 100 to 100 solder and rosin being used as flux.

Slag or Gravel Roofing

The Ordinary Gravel Roofing over boards is formed by first covering the rface of the roof with dry felt (paper) and over this laying three, four, or five yers of tarred or asphaltic felt lapping each other like shingles, so that only ›m 6 to 10 in of each layer are exposed. In laying roofs over concrete the dry lt is omitted, a mopping of pitch is placed directly on the concrete and the first yer of the felt embedded in it.

Flashing against walls, chimneys, curbs of skylights, etc., is done by turning e felt up 6 in against the walls. Over this is laid an 8-in strip with half its dth on the roof. The upper edge of the strip and of the several layers of felt is en fastened to the walls by nailing wooden strips or laths over the felt and into e walls. Metal flashings to protect the felt are better than the wooden strips d should be used when possible. At the eaves and on all exposed edges, etal gravel-stops should be used.

A Better Method of Slag or Gravel Roofing is to lay two plies of tarred felt, pping each other 17 in, and then spreading a coat of pitch over the entire roof. i this again three more layers of felt are laid and then coated with pitch, into iich the crushed slag or screened gravel is embedded.

Specifications for Pitch-Slag or Gravel Roofing. The following specifi-tion-notes * describe the latter method more in detail and also the materials at should be used to secure a first-class job. These roofs are most efficient and irable on comparatively flat inclines. The usual built-up roof consists of suc-ssive layers of saturated felt cemented together and surfaced with coal-tar tch or asphalt, into which is embedded the gravel or slag. Tile is also used as a rfacing material. The saturants used in the felt are generally coal-tar or phalt-compounds.

(1) Specification for Pitch-Slag or Pitch-Gravel Roofing Over Wooden Sheathing

This specification should not be used when the roof-incline exceeds 3 in to 1 ft.

Lay one thickness of sheathing-paper or unsaturated felt weighing not less an 5 lb per 100 sq ft, lapping the sheets at least 1 in.

Over the entire surface lay two plies † of tarred felt, lapping each sheet 17 in er the preceding one, and nail as often as is necessary to hold them in pla til the remaining felt is laid.

Coat the entire surface uniformly with pitch.

* Condensed and adapted from the roofing specifications published by the Barrett mpany and known, in their full form, as "The Barrett Specifications." They can be tained from the manufacturers.

† In the Western States the number of "plies" is construed to mean the total num-r of layers, including dry as well as saturated felt, and the terms 3-ply, 5-ply, etc., are reinafter used on that basis. In the Eastern States, 3-ply, 5-ply, etc., usually refers the number of layers of saturated felt. The total number of layers should always be ecified if there is any doubt as to the exact meaning of the term as used in the speci-ations.

Over the entire surface lay three plies of tarred felt, lapping each sheet 22 i over the preceding one and mopping with pitch the full 22 in on each sheet, s that in no place felt touches felt. Do such nailing as is necessary so that all nai are covered by not less than two plies of felt.

Diagram of Gravel or Slag Roofing on Wooden Sheathing

Diagram of Gravel or Slag Roofing on Concrete Base

Spread over the entire surface a uniform coating of pitch, into which, wh hot, embed not less than 400 lb of gravel or 300 lb of slag to each 100 sq ft. Th grains of the gravel or slag are to be from ¼ to ⅝ in in size, and dry and free fro dirt.

The roof may be inspected before the gravel or slag is applied, by cutting a sl not less than 3 ft long at right-angles to the direction in which the felt is lai All felt and pitch is to bear the manufacturer's label.

(2) Specification for Pitch-Slag or Pitch-Gravel for Roofing over Concret

This specification should not be used when the roof-incline exceeds 3 in to th foot. When the incline exceeds 1 in to 1 ft the concrete must permit of nailing nailing-strips must be provided.

Coat the concrete uniformly with hot pitch

Over the entire surface lay two plies of tarred felt, lapping each sheet 17 i over the preceding one, mopping with pitch the full 17 in on each sheet, so th in no place felt touches felt.

Coat the entire surface uniformly with pitch.

Over the entire surface lay three plies of tarred felt, lapping each sheet 22 i over the preceding one and mopping with pitch the full 22 in on each sheet, that in no place felt touches felt.

Spread over the entire surface a uniform coating of pitch, into which wh

hot, embed not less than 400 lb of gravel or 300 lb of slag to each 100 sq ft. The grains of the gravel or slag are to be from ¼ to ⅝ in in size, and dry and free from dirt.

The roof may be inspected before the gravel or slag is applied, by cutting a slit not less than 3 ft long at right-angles to the direction in which the felt is laid. All felt and pitch is to bear the manufacturer's label.

Notes on Slag and Gravel Roofing. The difference between slag and gravel roofing is that for the former crushed slag is used instead of gravel. The greater the number of plies of tarred felt, the greater the amount of pitch that it is practical to use, and it is the pitch that gives life to the roof. As there are several different weights and qualities of tarred felt, a specification should state either the minimum weight per 100 sq ft, single thickness (the most practical weight is from 14 to 16 lb), or some known quality, such as Barrett's "Specification Tarred Felt." Felt weighing less than 12 lb per 100 sq ft is not economical even on the cheaper work. To comply with the Barrett specification the materials necessary for each 100 sq ft of completed roof are approximately as follows:

Over boards	Material	Over concrete
108 sq ft	Sheathing-paper	None
80 to 85 lb	Specification tarred felt	80 to 85 lb
120 to 160 lb	Specification-pitch	180 to 225 lb
400 lb	Gravel	400 lb
300 lb	Slag	300 lb

In estimating felt, the average weight is practically 15 lb per 100 sq ft, single thickness, and about 10% additional is required for laps. In estimating pitch the weather-conditions and expertness of the workmen will affect the amount necessary for the moppings and for a proper embedding of the gravel or slag. As there are several qualities of pitch, a specification should either specify it by name, such as "Specification-Pitch" or "Straight-Run Coal-Tar Pitch," or in specifying asphalt-pitch, the brand or origin should be plainly defined. The use of an under-layer of sheathing-paper next to board-sheathing is mainly for the purpose of preventing any pitch which might penetrate the felt from cementing the roofing to the sheathing. It is also of value in preventing the drying out of the roof from below through open joints. Where a less expensive roof is desired, four plies or three plies of saturated felt may be used. With the four plies there should be used from 90 to 100 lb of pitch per 100 sq ft of completed roof; and with the three plies from 70 to 80 lb of pitch.

Durability of Slag or Gravel Roofs. These roofs, mentioned in the preceding paragraph, will last from five to ten years, or even longer, depending upon the quality of the materials used and the care with which they have been applied. Roofing put on strictly as provided for in the standard specifications will last twenty years or more, and if a tile surface is used, instead of gravel or slag, the roofing will last as long as the structure itself.

Resistance to Fire, Acid-Fumes, Etc. The fire-resisting properties of the slag or gravel roof are due principally to the incombustible material on the surface. It is claimed that the gravel or slag tends to prevent the successive layers of felt and pitch from burning and the whole mass has a blanketing influence on fires originating within the building. Some carefully conducted tests seem to indicate that gravel roofing protects a wooden roof better than tin. The general effect of a fire upon gravel roofing is to soften the pitch or asphalt in the roofing,

to burn out the inflammable oil in them and to cause the residue to swell and in a porous, incombustible coke. This type of roofing is not attacked by corrosive gases or acid-fumes, and is used extensively on railroad-roundhouses and other structures where the conditions are particularly severe. Coal-tar or tar should not be added to the pitch to soften it.

Guarantee. Roofers generally give a five-year guarantee with gravel roof

Cost* of Pitch-Slag or Gravel Roofing. The cost of this type of roofing varies greatly, depending on the location, size and quality of the work, the extremes being approximately \$2.50 and \$3.50 per square for three-ply, \$3.50 and \$4.50 per square for four-ply, and \$4.50 and \$7.00 per square for five-ply roofs.

Asphalt-Gravel Roofing

Asphalt-Gravel or Asphalt-Slag Roofing differs from coal-tar roofing principally in the substitution of asphalt or asphaltic cement for the coal-tar pitch, for saturating the felt as well as for mopping and surface-coating. It is claimed that the oils of asphalt do not evaporate as quickly as do those of coal-tar pitch under ordinary temperatures and that therefore the flexibility and life of asphaltic felt and coatings are not as quickly destroyed. As a matter of fact, asphalt roofs do not always last longer than some coal-tar roofs, but the chances are that they will last fully as long and possibly longer, depending upon the quality of the materials and the workmanship. The asphalt used for roofing is obtained principally from the island of Trinidad.

Specifications for Asphalt Roofing.† The following specifications were prepared by the above-named company and are for Warren's heavy standard Anchor-brand roofing. The manner of laying the felting differs from that ordinarily employed for coal-tar roofing.

(1) Specification for Asphalt-Gravel Roofing Over Wooden Sheathing

Cover the roof with two thicknesses of Warren's Composite roofing-felt manila-paper side down, lapping each sheet 17 in over the preceding one, and securing with nails through tin discs about 2½ ft apart.

Over the entire surface of the Composite felt thus laid, mop an even coating of Warren's Anchor Brand roofing-cement, into which, while hot, lay two thicknesses of Anchor Brand felt, lapping each sheet 17 in over the sheet preceding, sticking these laps the full width with hot Anchor cement and securing with nails through tin discs not more than 20 in apart.

Over the entire surface of the felt thus prepared, spread an even coating of the cement, covering it immediately with a sufficient body of well-screened, dry gravel or crushed slag.

If the roofing is applied in cold weather the gravel or slag must be heated.

Slag only should be used if the incline of the roof exceeds 3 in to the foot.

All layers of felt must be turned up at least 4 in over battlement-walls, skylight-curbs, or any projections raised above the roof.

(2) Specification for Asphalt-Gravel Roofing Over Concrete

The concrete foundation is to be smooth and perfectly graded to carry the water to the outlets or gutters.

Over the entire surface of the concrete first mop a smooth, even coating of Eclipse Asphalt cement, into which, while hot, lay two thicknesses of Warren's Anchor Brand roofing-felt, lapping each sheet 17 in over the sheet preceding

* These prices have advanced and the manufacturers' lists must be consulted.

†The asphalt-roofing materials manufactured by the Warren Chemical & Manufacturing Company of New York have been used for many years and have given good satisfaction.

Mop back for the full width between the laps of the felt thus laid, with War-n's Anchor Brand roofing-cement.

Over the entire exposed surface of the felt mop an even coating of said Anchor ment, into which, while hot, lay two thicknesses of Anchor Brand felt, lapping ch sheet 17 in over the sheet preceding, and sticking these laps thoroughly the ll width with hot cement.

Over the entire surface of the felt thus prepared, spread an even coating of the ment, covering it immediately with a sufficient body of well-screened, dry avel or crushed slag.

If the roofing is applied in cold weather, the gravel or slag must be heated. Slag only should be used if incline of roof exceeds 3 in to the foot. On steep rfaces nailing-strips should be provided in the concrete, unless the latter is fficiently soft to admit of nailing. All layers of felt must be turned up at ast 4 in over battlement-walls and skylight-curbs, or any projections raised ove the roof.

Cost of Asphalt-Gravel or Slag Roofing. Asphalt-gravel roofing costs a tle more than pitch-gravel roofing of the same grade. (See Cost of Pitch-ag or Gravel Roofing, page 1598.)

Roof-Incline.* Asphalt-gravel or asphalt-slag roofing should not be applied roofs which are steep enough to make the material run in hot weather. The anufacturers of various roofings will guarantee the permanency of their roofings r certain maximum slopes.

Prepared Roofing. There is a large number of so-called PREPARED ROOFINGS READY ROOFINGS, which are made by cementing together two, three, or more yers of saturated felt or felt and burlap and then coating the combination either ith a hard solution of the same cementing material, or with hot pitch or asphalt to which is embedded sand or fine gravel. These roofings are commonly put in rolls 36 in wide and are applied by lapping the strips 2 in with a coat of menting material between, and nailing every 2 or 3 in with tin-capped roofing-ils. A sufficient quantity of cement, nails and tin caps is packed in the middle the rolls. The particular advantage of these roofings is that no previous expe-ence is required for laying them and no kettles are required; for this reason they e extensively used in the country, and on railroad-shops, factories, and mill-ildings. In cities there is no particular advantage in using them except for ofs that are too steep for coal-tar pitch, as they cost on the roof about the same good gravel roofing. Many of these prepared roofings are as durable under or-nary conditions as the light-weight gravel roofs. In Colorado, however, it has en found that they are badly damaged by severe hail-storms, probably owing the lack of the protecting gravel. For roofs having a rise of 1 in or more to e foot, these roofings make economical and durable roofs, and for some build-gs are to be preferred to other materials.

Corrugated Iron and Steel Sheets

Corrugated Sheets of iron and steel are very extensively used for the roofing d siding of mills, sheds, grain-elevators and warehouses. The best grades of rugated sheets are now made of double-refined box-annealed iron or steel.†

* The Editor has been notified by the Warren Chemical & Manufacturing Company, w York, that when put on according to their directions, their Anchor Brand roofing has n successfully used on relatively steep surfaces where the slope was as high as 9 in to the t.

† It is claimed that "the life of a genuine PUDDLED-IRON sheet when exposed only to pure air and natural elements is from five to eight times longer, and when exposed to

The corrugations are usually made lengthwise of the sheet, either by passing them through rolls or by pressing the plain sheets in a press made to give the desired corrugations. It is claimed that the latter method gives the more perfect and uniform corrugations. The weight and thickness of the metal is represented by the gauge-number of the black sheets from which the corrugated sheets are made. The standard gauge* for sheet iron and steel in this country is that established by act of Congress, March 3, 1893. (See page 402.)

Gauges. The following table gives the weights and thicknesses of the different gauges, from No. 7 to No. 30, for flat BLACK SHEETS. The gauge extends from No. 7-0, ½ in thick, up to No. 40, 0.005469 in thick, but sheet steel is not commonly made thinner than No. 30, and above 3/16 in, the thickness is generally designated by fractions of an inch. Section 3 of the act of Congress provides that in the practical use and application of this gauge, a variation of 2½% either way may be allowed.

United States Standard Gauge for Sheet Iron and Steel *

The least pitch which should be given to roofs that are to be covered with orrugated sheets is 3 in to the foot, and for trussed roofs it is not desirable to

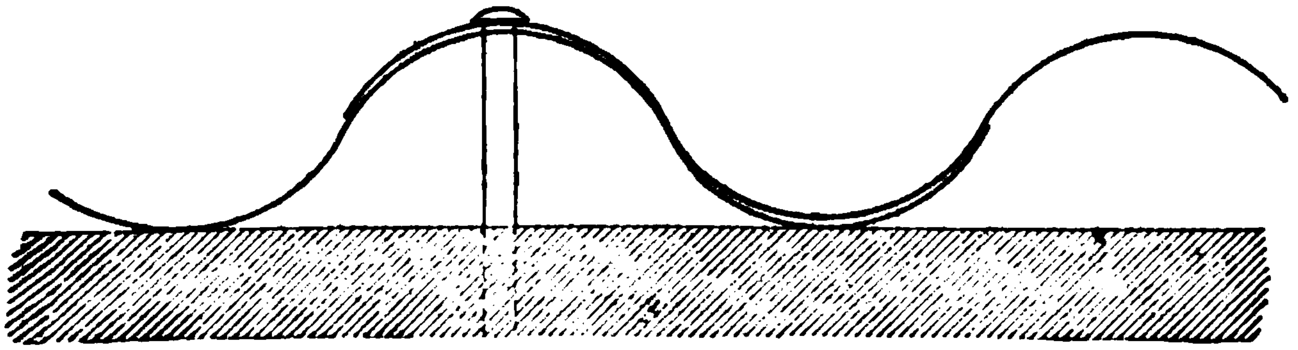

Fig. 1. Approved Method of Laying for Side Lap

ave less than a one-fourth pitch (6 in to the foot). When laid on a roof, corru- ated sheets should have a lap at the lower end of from 3 to 6 in, according to he pitch of the roof. For a ⅓ pitch, a 3-in lap is used; for a ¼ pitch, a 4-in ıp; and for a ⅙ pitch, a 5-in lap. For the side lap it is recommended that ach alternate sheet be laid upside down and lapped as shown in Fig. 1. By his method, when water is blown through the first lap, it will stop and not pass he half lap, but run down and out at the end of the sheet. A great deal of oofing, however, is laid as in Fig. 2. In applying to sheathing or wooden strips, he sheets are secured by nailing through the tops of the corrugations, the nails eing driven through every alternate corrugation at the ends, and about 8 in

* Much practical information regarding the use of corrugated sheets on mill-build- ıgs, with many details, is contained in Steel Mill Buildings and in the Structural En- ineers' Handbook, by Milo S. Ketchum.

† For the strength of corrugated sheets, see the books above mentioned.

apart at the sides. When applied to iron or steel purlins, the side laps shou extend over at least 1½ corrugations, and the sheets should be riveted togeth every 8 in on the sides and at every alternate corrugation at the ends. Th Cincinnati Corrugating Company makes a patent edge-corrugation whic makes a tight joint with a lap of only one corrugation. To fasten the sheets t

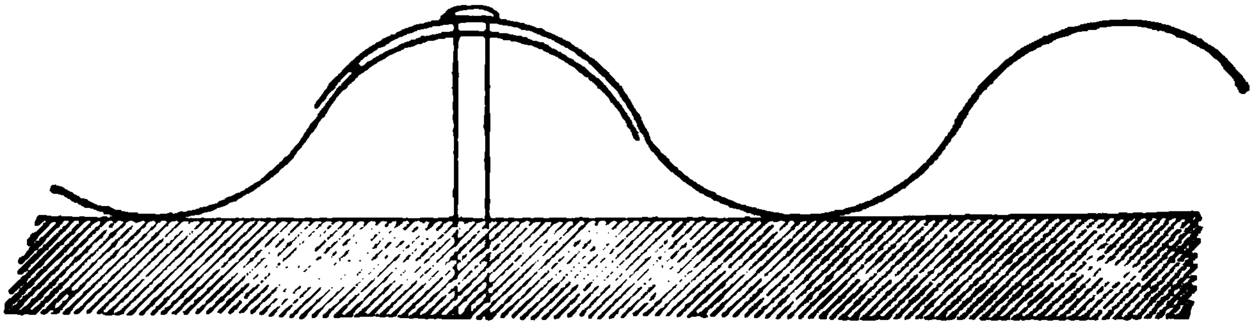

Fig. 2. Common Method of Laying for Side Lap

the purlins, which are usually steel angles, cleats of band-iron, ¾ or ⅞ in wid may be passed around or under the purlins and riveted at both ends to th sheets, as shown in Fig. 3. By contracting or pressing these cleats toward th web, a tight, secure fastening results, which allows for contraction and expansi of the sheets. Cleats, however, are generally used only with channel or Z-ba

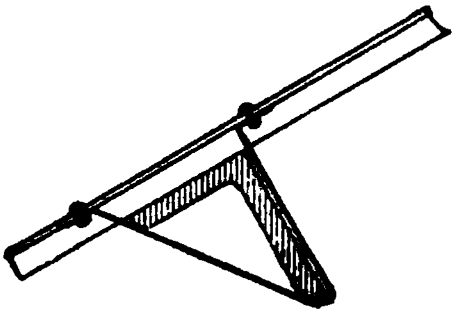

Fig. 3. Sheets Fastened to Angle-purlin by Band-iron Cleats

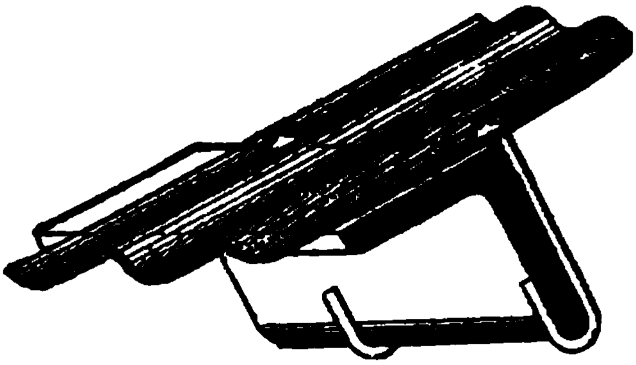

Fig. 4. Sheets Fastened to Angle-purlin by Clinch-nails

purlins. For angle-iron purlins, clinch-nails, made of soft-iron wire, are com monly used, as shown in Fig. 4; they make very satisfactory fastenings.

The following table shows the sizes of clinch-nails to be used with differe sizes of angle-purlins and also the number of nails to the pound in each instanc

Purlin-angles....................	2×2 in	2½×3 in	3½×3½ in	4×4½ i
Lengths of nails.................	4 in	5 in	6 in	7 in
Number of nails per pound......	48	38	33	27

The nails should be placed through the TOP of every second or third corru tion. At the eaves of the building and along the edges of the ventilators spec pains should be taken in fastening the roofing, as these are the places where th force of the wind is the greatest and where it tends to strip the roofing from th purlins. For these parts of the roof the best method of fastening is that show in Fig. 5. These fastenings consist of strips of sheet iron about 2 in wider tha the purlins, made of No. 12 iron and riveted to the purlins with ¼-in rive spaced 10 in apart. To these strips the corrugated sheets are riveted, eve 5 in or every two corrugates, with 6-lb rivets. The method of fastening show in Fig. 6, also, answers very well and is less expensive.

n ordering corrugated sheets an allowance must be made for the laps. The owing table gives the number of square feet necessary to cover one square of

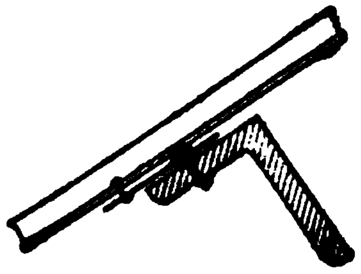

Fig. 5. Approved Fastening for Sheets at Eaves

nti-Condensation Lining. Wherever corrugated steel is laid on purlins no sheathing or paper underneath, if the building is heated, moisture will riably collect on the under side, and if the air in the building is warm and id, considerable dripping will result. To prevent this dripping, it is neces- to protect the under side of the corrugated steel with paper or felt. This be done by first stretching poultry-netting over the purlins, from eaves to e, and wiring the strips together at the edges. Over this should be laid one kness of asbestos paper and one or two layers of saturated felt. The cor- ted steel may then be fastened to the purlins in the usual way. The side may be secured by stove-bolts, with 1 by ⅛ by 4-in plate washers on the r side, to support the lining.

Corrugated Siding

r Siding, either the 2½, 2, or 1¼-in corrugations are used. The 1¼-in size, ever, makes the best appearance. For the laps, 1 in at the bottom and one gation at the sides are sufficient.

r Sheds, etc., the sheets may be nailed to cross-pieces cut in between the s horizontally and spaced from 2 to 3 ft apart, the studs being from 3 to 4 ft

on centers. For elevators, either cross-corrugated sheets or sheets not l than 32 in long should be used. The nails should be driven in the troug each alternate corrugation, 2 in above the lower end of the sheet, which wi 1 in ABOVE the top end of the under sheet. This allows the sheet to slide in 32 in as the building settles, before the nail will strike the upper end of lower sheet. The side lap should not be nailed.

Ceilings. For the ceilings of stores, stables, etc., 3/16 or 5/8-in corrug sheets are much used; and the construction is an excellent one for purpose.

Galvanized Iron. This term is commonly applied to all galvanized s metal. Formerly most of the galvanized sheets had a steel base, but s about 1906 a nearly pure iron, called Toncan Metal, has been largely used sheets of very fine quality. Galvanized sheets come in lengths of 6, 7 and in United States Gauge-Nos. 14, 16, 18, 20, 22, 24, 26, 27, 28 and 30, an widths of 24, 26, 28, 30 and 36 in for all gauges except No. 30, which is made in widths of 24, 26 and 28 in. Sheets of No. 28 gauge are also made in widt 32 and 34 in. The widths commonly carried in stock are 24, 28 and 3 Most of the galvanized iron used for cornices and ornamental work is No gauge. No. 28 is sometimes used for gutters and conductors.

Copper for Roofs

Method of Applying. This is usually in 2½ by 5-ft sheets, making sq ft and weighing from 10 to 14 lb per sheet. It is laid on boards to whi is fastened by copper cleats. No solder is employed, as it is in tin roofs, in horizontal joints, and the horizontal and sloping joints are made by simply o lapping and bending the sheets. The horizontal joints are locked together then tightly flattened down.

MEMORANDA ON TILING

Floor-Tiling and Wall-Tiling

Tile Floors are extensively used in the better class of buildings, and ticularly in those portions which are used by the public, on account of their durability, sanitary qualities and decorative effects. As a matter of fact a tile floor is also cheaper in the long run than a wooden floor if it is subje much wear. The materials used for tiling floors are tiles made from diff grades of clay, marble, slate, glass and rubber. Of these probably the m durable and sanitary are the vitreous clay tiles. For walls and wainscoti glazed tiles, marbles and glass are extensively used.

Floor-Tiles. The following include some of the principle kinds of clay

(1) **Common Encaustic Tiles.** These belong to the cheapest grades, and made of naturally colored clays, red, buff, gray, chocolate and black. T tiles are of a porous, absorbent nature and are used for common floors w sanitary requirements are not exacting.

(2) **Semivitreous Tiles.** These belong to a somewhat better grade than first mentioned and are less porous and absorbent.

(3) **Vitreous Tiles.** These are the hardest tiles known, cannot be scrat by steel or sand, and are non-absorbent and thoroughly aseptic. They are principally for floors requiring a perfect sanitary condition and are manufact in white, blue, gray, green and pink colors of great delicacy.

(?) Ceramic Tiles or Ceramic Roman Mosaic. This material is made of [vit]REOUS clay in tesseral pieces representing the tesseræ of the Roman mosaics. [It i]s made into regular tiles ranging from ½ to ¾-in squares and also in hexagonal [sha]pes from ¾ in to 1 in in size. A rounded LOZENGE TILE is also manu[fac]tured to be laid in tesseral paving. (See, also, Flooring of Mosaic, Terrazzo, [etc.], page 1607.)

[T]he material itself is of great hardness and well suited for work of a monu[men]tal or public character. The even and regular texture of the tesseræ admits [the] adoption of DAMASK DESIGNS which have become identified and associated [with] this material. The minuteness of the tesseræ admits of a great range in [desi]gning and the following of the architectural lines. The ceramic Roman [mos]aic is much preferred to mosaic consisting of natural marbles, because of the [grea]t variety in colors and its greater durability. The vitreous-clay tiles are [imp]ervious to attacks of any acids contained in the atmosphere, while marbles, [espe]cially, are subject to rapid disintegration caused by the sulphuric acid con[tain]ed in the smoke-laden atmosphere of our cities.

[(?]) **Florentine Mosaics and Flint Tiles.** These are the largest and heaviest [tiles] manufactured in this country. They are either plain or inlaid and are in [use] especially in ecclesiastic work on account of their relation to mediæval [decorat]ication. The material is vitreous, annealed and tougher than it is brittle. [It is] also in use for exterior polychrome work.

[(?]) **Aseptic Tiles.** These are large, heavy and thoroughly vitreous tiles used [for i]nstitute work. They are the only vitreous tiles of large size made in this [cou]ntry. As the tiles are large and generally of hexagonal shape, the joint[lin]es are reduced to a minimum, and they are, therefore, especially adapted [for h]ospitals, operating-rooms and wards for contagious diseases.

[E]nameled Tiles, Wall-Tiles and Mantel-Tiles. The following include [som]e of the enameled tiles:

[(?]) **White, Wall-Tiles.** These are glazed tiles for wainscots. They have [a wh]ite, soft body and a surface covered with a clear glaze. The brilliancy of [the] glaze and its reflecting properties make the white wall-tiles especially de[sirab]le for dark passages.

[(?)] **Colored, Glazed or Enameled Tiles.** These tiles are about the same as [the f]ormer in quality; the GLAZE or ENAMEL, however, is stained with metallic [oxid]es, which produces a brilliant decorative effect.

[(?)] **Dull-Satin, etc., Finished, Enameled Tiles.** These are glazed tiles with [DU]LL or BLIND enamel-finish. The dull finish is produced either by sand[blast]ing or by devitrifying enamels. It is principally used for quaint decorative [effect]s in mantel-work.

[(?)] **Glazed Roman Mosaics.** This is a type of enameled tiling which has [great] decorative possibilities. It has the same tesseral texture as the ceramic [mosaic] tiles and is readily applied to wainscots and mantel-work.

[Se]tting of Tiles. Clay tiles are set in Portland-cement mortar as a rule, [and f]looring of this character should always be provided with a substantial [concr]ete base. Ceramic mosaics are sometimes laid on a flexible base. With [this c]onstruction wooden floors can be provided with tile covering, and owing [to th]e elasticity and lightness of the material, floors in elevators, boats and other [buoy]ant structures can be safely tiled.

[Ma]rble Tiles, from 9 to 12 in square, have been extensively used for flooring, [princi]pally on account of their decorative effect. None of the marbles, however, [are as] hard and consequently as durable as the vitreous and ceramic tiles, and

from all practical standpoints the marbles do not make as good floor-co When used, they should be 1¼ in thick and not over 12 in square, and sh bedded in cement on a concrete base. Marbles should not be used for fl in hospitals, as they yield rapidly to the usual antiseptic floor-washes.

Slate, although non-absorbent and not affected even by dilute mineral a is too cold and dingy to commend itself for floor-tiles, but because it is co iently handled in large slabs it is valuable as a cheap base and as a co wiring and pipe-trenches in the floors. As these often follow a wall, it may in the capacity of a border and as such be extended around the floor- Slate slabs for floors should be about 1¼ in thick.

Marbleithic Tiles or Slabs are made of small pieces or chips of marb irregular shapes, set in a backing of sand and Portland cement. After th ment has set, the top surface is rubbed until it becomes flat and smooth. bleithic resembles mosaic or TERRAZZO, except that it is laid in the form of instead of being put down on the floor in a plastic condition. Much objectio been made to TERRAZZO because of the cracks which commonly occur in it, to the slight settlements which are unavoidable in a new building. (See, Flooring of Mosaic, Terrazzo, etc., page 1607.) With tile floors of any ma the joints allow for any slight movement of the floor-construction wi causing visible cracks. By the process of manufacture, marbleithic is much harder than it is possible to make mosaic floors that are laid in a pl condition, so that they have a much better wearing surface. Floors of material have been in use since 1895 and show little if any wear. Marbl tiles are made of various colored marbles and in different sizes, shapes patterns, so that a great variety of effects may be produced. Sanitary co bases, stair-treads, and wainscotings, also, are made of this material.

Cast-Glass Tiles, while quite resistant to a blow when the polish is broken, will break very easily when the surface is scratched. All glass should, therefore, be very thick and small or protected by metal framing.

Novus Sanitary Glass * is a sanitary structural glass manufactured i thicknesses from ½ in up to 2 in and in slabs of all widths and lengths up to in width and 180 in in length. It is made in various colors and designs a the following finishes: natural-fire finish, hone, semipolished and poli It can be worked and handled the same as marble, it is readily drilled and s to accommodate fixtures, etc., and is very handsome in appearance. It i pervious to discoloration and is non-crazing. These qualities make it espe desirable for floors, wainscoting, tables, shelves, etc., in all places where ab lutely sanitary condition combined with a handsome appearance is required

Interlocking Rubber Tiling

General Description. There is an interlocking rubber tiling,† which cause of its being noiseless, non-slippery, and more comfortable to the feet inelastic substances, has met with great favor for floors in banking-ro counting-rooms, vestibules, elevators, stairs, cafés, libraries, churches, etc. elevators it is one of the most durable and practical floors that can be it is also especially and peculiarly adapted for floors of yachts and steam The interlocking feature unites the tiles into a smooth, unbroken she rubber, unlimited in area. The tiles do not pull apart or come up, and being distinct, almost any color-scheme can be employed, the tiles being in a carefully selected variety of colors. The tiles are laid directly over

* Made by the Penn-American Plate Glass Company, Pittsburgh, Pa.
† Manufactured by the New York Belting and Packing Company, New York.

inal floor, like a carpet, except that they are not fastened. Experience has wn that they are very durable. Each tile is 2⅝ in square and ⅜ in thick; tiles are required to the square foot. Rubber nosing for stairs is made to rlock with the tiles.

Cost * of Different Tiles

pproximate Cost. The following prices are approximately the cost, to the le, at the factory. To these should be added the freight and the dealers' its. The cost of laying the tiles on a cement base, in addition to the cost he tiles, should not exceed 25 cts per sq ft.

Floor-Tiles

Kinds of tiles	Factory price per sq ft
mmon encaustic tiles, unglazed	15 cts
treous tiles, white	22½0 cts
lors, large sizes	from 23 to 26 cts
ramic tiles, or ceramic Roman mosaic	from 20 to 35 cts

Wall-Tiles and Mantel-Tiles

Kinds of tiles	Factory price per sq ft
iite glazed wall-tiles	23 cts
lored glazed or enameled tiles	35 cts
ameled tiles, dull satin-finish	50 cts
rbleithic, from 45 cts, upwards, laid	....
nd-made faience, plain colors	from $0.60 to $1

Flooring of Mosaic, Terrazzo,† etc.

looring of Mosaic Work is largely used. (See, also, Ceramic Tiles, or mic Roman Mosaic, page 1605, and Marbleithic Tiles, page 1606.) It is posed of small pieces of stone, marble, pottery or glass, usually laid in some mental design or pattern. A bed of concrete is first laid and the small s of the material used set in a floating of cement and made from ½ to 1 in . When cubes of varicolored marble are used, pressed into the cement ar, it is called ROMAN MOSAIC. A somewhat cheaper flooring is made by ding marble chips of irregular shape over the surface of the cement, ing them into it with plasterers' floats and rolling them with iron rollers. is called TERRAZZO MOSAIC. The following is from the specifications for new Field Museum, Chicago, Ill., D. H. Burnham, architects: "Filling r terrazzo shall be composed 1 part cement, 2 parts sand and 4 parts brick. re concrete filling commences to set spread a ¾-in wearing surface composed arble chips with only enough neat Portland cement to firmly unite the s. Trowel and roll, and after the mortar has set, rub the terrazzo to a oth, even surface and wash clean." "Terrazzo floors in the East cost from 30 cts per sq ft, contractor's profit included."‡

hese prices have advanced and the manufacturers' lists must be consulted.
ee article on Terrazzo Floors, by C. R. Marsh, in Journal of the Society of Construc- f Federal Buildings, July, 1914.
uoted from The New Estimator, by William Arthur, 1914.

ASPHALTUM

Bitumen, Asphaltum, Asphalt. "Bitumen is the name used to denote group of mineral substances, composed of different hydrocarbons, found wid diffused throughout the world in a variety of forms which grade from thin vo tile liquids to thick semifluids and solids, sometimes in a free or pure state, l more frequently intermixed with or saturating different kinds of inorganic organic matter. To designate the condition under which bitumen is fou different names are employed; thus the liquid varieties are known as NAPH and PETROLEUM, the semifluid or viscous as MALTHA OF MINERAL TAR, and t solid or compact as ASPHALTUM OF ASPHALT." *

Asphaltum is found in extensive beds or lake-like deposits on both contine the most notable of these are the PITCH lakes on the island of Trinidad, and Bermundez, Venezuela. It is also found saturating the limestone and sa stone formations in certain localities. Deposits of very nearly pure asphalt are found in Utah, Mexico, Cuba, and various parts of the United Sta ELATERITE, GILSONITE and WURTZILITE are varieties of very nearly pure asp tum.

Asphaltic Roofing-Materials are manufactured principally from Trinid asphalt. These deposits have also been the main source of supply for the a phaltum used in street-paving in the United States.

Rock-Asphalt. The term ROCK-ASPHALT is commonly used to designate t material obtained from the bituminous limestone deposits at Seyssel and Py mont, in the valley of the Rhône, France, in the Val-de-Travers, canton Neuchâtel, Switzerland, and at Ragusa, on the island of Sicily. It is extensi employed for paving purposes throughout Europe, and is considered to mak much more durable pavement than can be made with asphaltum. Ro asphalt is prepared for shipment in two forms: (1) COMPRESSED ASPHALT BLOC which are used for paving in much the same way as stone blocks, and (2) MAS ASPHALT, which is put up in cakes of varying shape, generally bearing the ma facturer's trade-mark.

Mastic-Asphalt. In the Eastern States MASTIC-ASPHALT is used for floors cellars, stores, breweries, malt-houses, hotel-kitchens, stables, laundries, c servatories, public buildings, carriage-factories, sugar-refineries, mills, rinks, and for any place where a hard, smooth, clean, dry, fire-proof and water-pr odorless and durable covering of a light color is required, either in the basem or upper stories. It can be laid over cement concrete, brick, or wood, in sheet without seams; also over cement concrete for roofs for fire-proof build For dwelling-house cellars, especially on moist or filled land, this materia especially adapted, being water-tight, non-absorbent, free from mold or impervious to sewer-gases, and for sanitary purposes, invaluable. Ma asphalt is also valuable for DAMP-COURSES over foundations, and for cove vaults and arches under ground.

Asphalt Floors and Pavements. For floors of cellars, courtyards, laid on the ground, a base of cement concrete 3 in thick should first be laid over this a layer of asphalt from ¾ in to 1½ in thick, according to the us which it is to be put. For ordinary cellar-floors, the asphalt need not be than ¾ in thick; for yards on which heavy teams are to drive, it should 1½ in thick. In specifying asphalt pavement, both the thickness of the conc and of the asphalt should be given; it should also be remembered that ASPH PAVEMENT does not include the CONCRETE FOUNDATION unless so specified.

* Byrne, Inspectors' Pocket Book.

ying asphalt over planks or boards, a layer of stout, dry, but not tarred, sheathg-paper should first be put down and the asphalt laid on this. Asphalt floors stables should be at least 1 in thick. Architects and owners desiring to emoy ROCK-ASPHALT for any of the above purposes should be careful to secure the nuine VAL-DE-TRAVERS, SEYSSEL, or SICILIAN ROCK-ASPHALT, as there are itations which are of but little value.

The Bituminous Sandstones of California have been extensively used for ving streets in Western cities. They are prepared for use as paving-materials crushing to powder. With this powder a considerable proportion of sand gravel is generally mixed and the mixture heated until it becomes plastic; it then spread over the roadways and compressed by rolling.

MINERAL WOOL

Sources of Mineral Wool. There are at least two kinds of mineral wool de in this country. The more common quality is made by mixing certain ds of stone with the MOLTEN SLAG from blast-furnaces and converting the ole mass into a fibrous state. The best slag for the purpose is that which is e from iron. The appearance of the finished product is much like that of ol, being soft and fibrous, but in no other respect are the materials alike. neral wool made from slag appears in a variety of colors, principally white, t often yellow or gray, and occasionally quite dark. The color, however, is d to be no indication of the quality, as all of the peculiar properties of the terial are present in equal proportions in any of the shades. The other kind mineral wool is known as ROCK-WOOL, and is made from granite rock raised to oo° F. It is claimed that as it is absolutely free from sulphur, it is the only rless wool manufactured. It has been approved by the United States War partment. It has the same general appearance as that made from slag, and white in color.

Nature of Mineral Wool. Both of these materials consist of a mass of very , pliant, but inelastic, vitreous fibers interlacing in every direction and ning an innumerable number of minute air-cells. Its great value in the insuon and protection of buildings lies in the number of air-cells which it contains, consequent non-conduction of heat, and its fire-resisting qualities. In wool de from common slag, 92% of the volume consists of air held in minute cells, le in the best grade the proportion of air reaches as high as 96%. This cond air makes it one of the best, if not the best, of the non-conductors of heat. de from these qualities it is very durable and contains nothing that can decay become musty. Being itself incombustible it greatly retards the burning of oden floors or partitions if their inner spaces are filled with it.

Uses of Mineral Wool. The greatest value of this material is as an insulaof heat, but it is also a valuable non-conductor of sound. It is the general nion, however, that it can be considered only as a MUFFLER of the soundes, for there seems to be no practical way in which it can be used so as to arate entirely the floor and ceiling. It would be crushed by laying floorts upon it. As a muffler or filling between the beams, however, there is bably nothing that is superior. In the end, then, it would seem that the t complete insulation from sound, without separate beams, would be obtained FLOATING the flooring on some material like Cabot's Quilt or on a very thick with the spaces between the floor-cleats filled with mineral wool.

Manner of Applying Mineral Wool. Mineral wool, when used alone as -deadening, may be laid on boards cut in between the joists, or on top of thing-lath when that material is used. The wool should be at least 2 in

thick. Again, mineral wool is particularly desirable for filling the spaces betw the studs of outside walls and partitions and between the rafters of roofs. may be used to great advantage, also, in partitions around bath-rooms or wa closets, and around water-pipes when placed in partitions. In outside w and attic roofs, as a protection from the heat of summer or the cold of wi it is of the greatest value. By lathing the under side of the rafters with she ing-lath, and spreading on top a layer of 2 or 3 in of mineral or rock-wool, t comfort of the room is greatly increased. Flat roofs over inhabited rooms m be covered with rough boards and 1¾-in cleats nailed on top, the spaces fi with wool, and the roof-sheathing then nailed to the cleats. This not o greatly increases the comfort of the rooms, but greatly retards the progres fire from the outside. When insulating against heat, nails driven through t insulating material do no harm. When using mineral wool in floors it should packed in very closely, but not jammed so as to break the fibers, which t naturally very brittle. In partitions it is packed between the studs and la so as to completely fill the spaces, the wool being put in after the lathing l reached a height of 2 or 3 ft. More laths are then put on, the spaces filled, a so on to the top. The wool should not be dropped from any considerable heig as the breaking up of the fibers destroys the insulating qualities of the mater In fact the tendency of mineral wool to settle and consolidate, if improperly too loosely packed, is the only drawback, except cost, to its use for insulat The wool behind the lathing will not prevent the plaster from keying.

Cost of Mineral Wool. Mineral wool is sold by the pound, and in estim ing the quantity of wool required, 1 lb per sq ft of filling, 1 in thick, should allowed for ordinary wool and ¾ lb for selected wool.

ESTIMATING THE COST OF BUILDINGS *

Cost of Buildings per Cubic Foot. The method of CUBIC-FOOT VALUES has been used more than any other in estimating the cost of any proposed building, before the plans and specifications are sufficiently complete for taking off the actual quantities. "Comparison of UNIT COSTS is the only scientific criterion by which to judge the economic merit of a structure, a machine or a method of doing work." † Two buildings in the same city, or district built in the same style and for the same purpose, of the same materials, and on the same scale of wages and prices of materials, should cost the same, or very nearly the same, per cubic foot, although one building may be somewhat larger than the other and of different shape. It therefore follows that if we know the COST PER CUBIC FOOT of different classes of buildings, in different localities, we can approximate quite closely the cost of any proposed building by multiplying its cubic contents in feet by the known cost per cubic foot of a similar building already built in that locality.

Size of Building Proportioned to Cost per Cubic Foot. If the cost of a proposed building must be kept absolutely within a certain sum, the size of the building should be proportioned so that the CUBIC CONTENTS shall not exceed the quotient obtained by dividing the amount appropriated by the AVERAGE COST PER CUBIC FOOT of similar buildings. Even then it may be found, when the bids are opened, that they exceed the appropriation; but the excess is often a relatively small percentage of the total cost and the necessary reductions can be made without altering the main features of the building.

Methods of Computation. In estimating the cost by the METHOD OF CUBIC CONTENTS, it is of course necessary that the contents be computed on the same basis, in both the proposed building and the one already built. The cubic contents are generally computed from the basement or cellar-floor, to the average height of a flat roof, or, if there is a pitched roof, the finished portion of the attic is included, or that part which might be finished, mere air-spaces and open porches not being included. Vaults and areas under sidewalks, etc., are generally included as part of the basement. All measurements are to the outside of the walls and foundations. The estimated cost may or may not include the fees of the architect and other experts.

Other Methods of Estimating the Cost of Buildings. The cost of buildings, such as hospitals, theaters, schools, churches, barracks, large stables, etc., is sometimes estimated by the COST PER BED, SITTING, INMATE, etc. Estimates are also based upon the COST PER SQUARE FOOT of GROUND OCCUPIED or of all the FLOOR-SPACE, in certain types of buildings.

* The editor is indebted to E. S. Hand and others for valuable data relating to this subject. Readers are referred to the Handbook of Cost Data for Contractors and Engineers, by H. P. Gillette, The New Building Estimator, by William Arthur, and The Building Estimator's Reference Book, by F. R. Walker. Values given are pre-war values and may be used for relative costs.

† H. P. Gillette, in the preface to his Handbook of Cost Data for Contractors and Engineers.

Data * on Cubic-Foot Values as a Basis for Preliminary Estimates of Building Costs

Notes on Modifying Conditions. Buildings of a given TYPE, such as offic buildings and school-buildings, when similar in construction and finish and bu under similar market-conditions as to cost of labor and materials, are found t be nearly identical in CUBIC-FOOT COSTS. The buildings of any such type do n differ widely in bulk, and this is always very considerable when compared wit such structures as dwellings and small business buildings. This seems on another way of saying that similar causes produce similar effects, but it goes step farther by indicating that the results here are virtually identical; so near so, that the AVERAGE CUBIC-FOOT COST of a certain kind of building can be reli on to produce an estimate within from 3 to 5% of the actual cost of new work o the same kind and under the same conditions. Other types of large structure such as public buildings, hotels, churches and theaters, are less subject to stand ardization because more variable in equipment and finish. This is true also dwellings, shops and other small structures whose lesser bulk, moreover, rende even less possible a close prediction as to their cost. These uncertainties do no however, warrant the rejection of the CUBIC-FOOT-COST METHOD for prelimina estimating. They do indicate that it is less closely approximate for some type than for others. But the degree of uncertainty on even the most variab types may be minimized and should be reduced to perhaps 10% under a caref system of cost-computation. Such system should cover a considerable numbe of examples, taking account of all factors of material influence upon cost in eac type, and must follow a consistently uniform method of determining cubic-foo values.

The Factors Which Influence Cost include the following.

(1) Prevailing market prices of labor and materials.

(2) Type of construction employed, depth and kind of foundations and exist ence of special features such as towers or domes.

(3) Finish: external facing and ornamentation; internal surfacing and deco ration.

(4) Equipment: (*a*) number and complexity of heating, lighting, ventilati sanitary, elevator and other systems; (*b*) extent to which appara or equipment, such as laboratory-devices, opera-chairs, bank-counte etc., is provided for direct use of occupants of building.

(5) Fees of architect and other experts.

(6) Locality. Costs of structures of a given type will vary with the locali because of differing standards of practice and building laws, availabil of building materials, labor, etc.

(7) Other items, developing in the experience of the architect.

The Method of Determining Cubage may either simply recognize GEOMETRICAL VOLUME of the building or, better, may employ a COEFFICI OF VALUE for any part whose cost varies materially from the average. T latter method may be preferred as allowing a closer calculation of variat from known examples. For instance, an unfinished cellar or other story o small light-court would cost less per cubic foot than the remainder of the bu

* The data on this page and page 1613 on cubic-foot values are quoted, by per sion, from notes relating to this subject, compiled by Professor Warren P. Laird the study of a large number of public and private buildings erected in widely sepa districts of the United States. For these buildings Professor Laird acted as the pro sional adviser for the selection of the architect, and in all cases the estimate of the of the buildings was based strictly upon a total number of cubic feet and a fixed cost per cubic foot.

ıg, while a tower or dome of finished basement containing, also, an expensive ɩechanical plant, would cost more. Foundations sometimes cost so much ıat they require figuring to their full depths as though the finished building ere carried down to that level.

Cubic-Foot Costs. Subject to the foregoing considerations, the following ıta on fire-proof buildings were average pre-war values. These unit prices no nger prevail as labor and materials have in some cases almost doubled in cost nce the war. The values must be increased from 50 to 100%, depending upon ıe kind of building.

Construction: steel and terra-cotta, stone and brick facings, complete equipent and superior grade of interior finish:

Type of building	Cents per cubic foot
Office-buildings	32 to 35
Public buildings	40 to 45
School-buildings	20 to 25

Construction: reinforced concrete; facing, common brick; equipment, type ual in such structures; inside finish, the simplest.

Type of building	Cents per cubic foot *
Factories †	14 to 16
Lofts †	15 to 18

ıble for Estimating Roughly the Approximate Cost of Some Small Buildings

Based on prices for labor and materials in 1920. The cost of first-class fireɔof buildings is greater in the Western and Southern States than in the Eastern ıtes, because of the distance from the great steel and material-centers.

Farm and Country Property

	Cost per cubic foot, cents
vellings, frame; small box house, no cornice	10
vellings, frame; shingle roof, small cornice, no sash weights, plain.	12 to 14
vellings, brick; same class	16 to 18
vellings, frame; shingle roof, good cornice, sash weights, blinds (good house)	16 to 18
vellings, brick; same class (good house)	20 to 22
rns, frame; shingle roof, not painted, plain finish	4 to 6
rns, frame; shingle roof, painted, good foundation	6 to 8
res, frame; shingle roof, painted, plain finish	12 to 16
res, brick; shingle roof, painted, good cornice, well finished	16 to 20
linary frame churches and schoolhouses; country	12 to 16

These pre-war values must be increased from 50% to 100%, depending upon the kind uilding.

If such subcontracts as plumbing, heating, lighting-fixtures, elevators, etc., are not uded, of course these figures were reduced. See Cost of Reinforced-Concrete Build-, page 1618.

Brick churches and schoolhouses; country........................ 18
If the roofs are slate or metal, add ¼ ct per cu ft.

City and Village Property

Dwellings, frame; shingle roof, pine floors and finish, no bathroom or furnace, plain finish (good house)........................ 14
Dwellings, brick; same class........................ 15
Dwellings, frame; shingle roof, hard-wood floor in hall and parlor, bath, furnace, and fair plumbing........................ 18
Dwellings, brick; same class........................ 18
Dwellings, frame; shingle roof, hard-wood in first story, good plumbing, furnace, artistic design, some interior ornamentation, well painted........................ 22
Dwellings, brick; with good plumbing, bath, hot and cold water, pine finish, well painted, no hard-wood finish........................ 24

Examples of Actual Costs of Pre-war Buildings per Cubic Foot

In order to illustrate the subject further, examples of buildings erec before the war are given. The lists were furnished through the courtesy of architects of the buildings. Such lists could be indefinitely extended, but th submitted are deemed sufficient to give some idea of the similarities and va tions of costs based upon cubage. With the exception of reinforced-conc buildings, it is probably true that for twenty or twenty-five years (1890 to 19 the cost of buildings increased, with some variations in the rate of increase, the rate of about 1% per year. Costs have increased since the war from 5 100%, depending upon the kind of building.

Examples of the Actual Cost of Pre-war Buildings per Cubic Foot

These buildings were designed by Boring & Tilton

ame and location of building	Date	Height and type	Approximate cost	Cost per cubic foot, cents
emorial Hall, Tome Institute, Port Deposit, Md.	1900	Three stories and basement, fire-proof	$150 000	16
'est Side Branch Library, Cleveland, Ohio	1908	One story and basement, non-fire-proof	85 000	17
tamford Grammar School, Stamford, Conn.	1908	Two stories and basement, non-fire-proof	50 000	15
t. Agatha's School, 87th St. and West End Ave., New York City	1907	Six stories and basement, fire-proof	275 000	29
merican Seamen's Friend Society, Jane and West Sts., New York City	1909	Five stories and basement, fire-proof	200 000	32
astern District Branch Y.M.C.A., Brooklyn, N.Y.	1906–1909	Six stories and basement, fire-proof	255 000	27
arrytown Hospital, Tarrytown, N. Y.	1910	Two stories and basement, non-fire-proof	65 000	26
lair Hospital, Huntingdon, Pa.	1909	Three stories and basement, fire-proof	90 000	20
lizabeth Library, Elizabeth, N. J.	1912	Three stories and basement, fire-proof	100 000	35
pringfield Library, Springfield, Mass.	1908	Two stories, mezzanine and basement, fire-proof	350 000	35
ioux City Library, Sioux City, Iowa	1912	Two stories and basement, non-fire-proof	75 000	21½
11 Park Avenue, New York City	1912	Twelve stories and basement, fire-proof	350 000	45
'nited States Immigrant Station, Ellis Island, New York Harbor. Main building	1898	Two stories and basement, fire-proof	625 000	17½
lospital building	1898	Three stories and basement, fire-proof	150 000	28
lount St. Mary's College, Plainfield, N. J.	1912	Three stories and basement, fire-proof	250 000	22

These buildings were designed by Palmer, Hornbostle & Jones

Name and location of building	Date	Notes	Cubic contents, cubic feet	Approximate cost *	Cost * per cubic foot, cents
Oakland City Hall, Oakland, Cal.	1914	Based on all contracts except for lighting-fixtures	2 999 442	$1 400 000	[illegible]
Allegheny County Soldiers' Memorial, Pittsburgh, Pa.	1911	....	2 855 892	913 721	32
New York State Education Building, Albany, N. Y.	1912	Original contract completed, Dec. 1912	11 281 691	3 744 521	33¼

These buildings were designed by Robert D. Kohn

Name and location of building	Date	Height, character of construction and finish	Cost * per cubic foot, cents
Hermitage Hotel, New York City.	1907	Size of lot, 50 by 100 ft; height, 150 ft; 15 bedrooms and 11 baths on each floor; basement and sub-basement; power, electric light and refrigerating-plants; complete kitchen-equipment; brick and limestone exterior; cement floors.	[illegible]
Trades School Building, Manassas, Va.	1910	Main wing, 50 by 100 ft, two and one-half stories; shop-wing, 75 by 105 ft, one story, brick; shops, mill-constructed roof, cement floor; brick exterior throughout; heating-plant in extension; common wooden-floor construction, tin roof, class-rooms plastered; cheaply built.	[illegible]
Ethical Culture Meeting House.	1910	Height, 100 ft; basement, assembly-room; main floor, auditorium for 1 200 people; two stories above auditorium, Sunday school and offices; limestone exterior; fire-proof construction; oak finish.	[illegible]

Cost * of Some Notable Buildings in New York City. Some of th prominent buildings in the Borough of Manhattan, City of New York, a cluded in the following table. For all these structures the costs per cubi are given. By reason of its height the Woolworth Building may be consid the most notable of the list. It is not only the highest building in Ne City or the United States, but in the world. The cubic contents total 12 000 000 cu ft. Its foundations are carried to rock, which is about below the street-surface. The approximate weight of its steel frame is tons.

* See notes on cost on page 1614.

Cost-Data * of Some Notable Pre-war Buildings in New York City †

			Ground-areas, sq ft	Total floor-areas, sq ft	Cost	Cubic contents, cu ft	Costs per cubic foot, cents
Altman Building [1]	8-story department-store	152	54 850	495 000	....	....	33
Banker's Trust Co.'s Building [1]	39-story office-building	566	9 721	345 000	....	....	70
Heckscher Building [2]	50 E. 42nd St.	317	10 750	147 172	$700 000	1 793 351	39
Masonic Building [3]	19-story lofts and meeting-rooms	292	23 300	432 000	2 250 000	5 701 000	39
Walker-Lispenard Building [4]	24-story telephone-exchange	365	27 580‡	....	....	....	40
Woolworth Building [5]	55-story office-building	792	15 600	790 000	....	7 250 000	62⅙
United States Rubber Co.'s Building [6]	20-story office-building	273	10 800	276 000	1 628 707	3 090 205	52⁷⁄₁₀

Auerbach Candy-Factory [8]	11-story factory	163	35 100	343 680	915 000	5 200 000	17½
Æolian Building [9]	17-story lofts	248	15 700	244 724	2 000 000	4 225 000	47⅓

* See notes on cost on page 1614.
† The editor is greatly indebted to Mr. E. S. Hand and to the architects mentioned for the date for this table. ‡ Typical floor-area.

These buildings were designed by the following architects: [1] Trowbridge & Livingston; [2] Jardine, Hill & Murdock; [3] H. P. Knowles; [4] McKenzie, Voorhees & Gmelin; [5] Cass Gilbert; [6] Carrère & Hastings; [7] Charles A. Valentine; [8] Robert D. Kohn; [9] Warren & Wetmore.

The Grand Central Station, as a complete terminal, is a very complex stru-ture, but there is a distinct part which contains the passenger-concourse and the waiting-rooms, restaurant and other parts that are considered necessary to care for the traffic. The cubic contents of this part total about 14 000 000 cu ft. Other parts of the building are not considered in the present reference. Some interesting facts as to the main station, only, are:

Cost,* about	$8 000 000
Ground-area above street-level, square feet	266 000
Additional station-facilities under street, square feet	80 000
Floor-area devoted to station-purposes, square feet	1 188 000
Cubic contents, about, cubic feet	32 857 800
Steel used in construction, tons	35 767
Weight of largest girder used, tons	30

Costs* of Pre-war Reinforced-Concrete Buildings.†‡ In judging the cost of a building by CUBICAL CONTENT or by AREAS OF FLOORS the shape of the build-ing in plan should be taken into consideration. A long, narrow building will cost more per cubic or square foot than one more nearly square in plan; and in computing costs by the cubic-foot or square-foot unit prices these conditions as well as the judgment and experience of the architect or engineer who makes the estimates affect the accuracy of the results. The following notes quoted from data furnished by the architects and engineers of the buildings mentioned include useful information relating to costs of some reinforced-concrete buildings of different types, erected in Philadelphia and vicinity (1906–1915).

(1) ' A reinforced-concrete building of the FACTORY-TYPE, erected (1914-15) in the City of Philadelphia. It is a concrete cage, with no brick veneer, four stories in height, no basement, size, 60 by 159 ft, stair-shafts and elevator shafts projecting beyond the building; cubical contents, 603 000 cu ft. The cost, without equipment, was 7½ cts per cu ft. Drainage is included in this price, but no plumbing, heating, lighting or elevators. The total floor-area of the building is 40 140 sq ft and the cost per square foot is $1.14½. This is built according to the building laws of Philadelphia.

(2) "A MILL-CONSTRUCTED BUILDING, about the same size as building (1) recently erected in a manufacturing town forty miles from Philadelphia. It is four stories in height and has a part-basement, a wing 30 by 40 ft, and a one story boiler-room and engine-room. The total cubical contents are 524 [illegible] cu ft, and the cost, 6⅛ cts per cu ft. The total floor-area is 37 900 sq ft, and the cost, $0.85⅛ per sq ft. This is without power, heat, or light. There are a few plumbing-fixtures in this building.

"In comparing the costs of the two buildings, it must be borne in mind that one is located forty miles from Philadelphia, and was not erected under the rigid building laws that are in force there. It is usually possible to erect a building of any type at less expense outside of Philadelphia than in that city and this can probably be said of any city where there are no state building codes

(3) "A MILL-CONSTRUCTED BUILDING, three stories in height, erected in 19[illegible] in Camden, N. J., and having 575 044 cu ft. It cost 7 cents per cu ft. It has 38 912 sq ft of floor-area, at a cost of $1.04 per sq ft. This price is without power, heat, light, or elevators, but includes some plumbing.

(4) "The new municipal REPAIR-SHOP of the City of Philadelphia. This is a reinforced-concrete building with brick veneer of an ornamental type, and cost 9⅛ cts per cu ft for 1 080 591 cu ft or $1.74 per sq ft for 57 323 sq ft of total

* See notes on costs on page 1614. Prices given must be at least doubled (1920).

† Valuable data on this subject have been furnished the Editor by Ballinger & Perrot the architects and engineers of the five reinforced-concrete buildings described.

‡ See, also, page 1613.

r-area. This is without plumbing, power, heat, light, or elevators. The tively high cost per square foot for this building is due to the fact that the ne run-way takes up a considerable portion of the building, so that a floor mitted where the crane is placed, and the floor-area accordingly reduced.

5) "The new building for the AUTOMOBILE CLUB of Philadelphia. This is hree-story building, of reinforced-concrete cage-construction, and contains 1 966 cu ft, at a cost of 10⅝ cts per cu ft. The total floor-area is 90 602 t, costing $1.54 per sq ft. This is without power, heat, light, or any equipnt, but includes plumbing. The shape of this building favors economy of struction, as it is nearly square in plan."

n summing up the conclusions arrived at in regard to the average costs of forced buildings, E. G. Perrot states * that the cost can best be considered classifying them under three general heads:

1) Warehouses and manufactories. Cost, from 8 to 11 cts per cu ft.

2) Stores and loft-buildings. Cost, from 11 to 17 cts per cu ft.

3) Miscellaneous buildings, such as school-houses, hospitals, etc. Cost from to 20 cts per cu ft.

Cost of Mills and Factories Built on the Slow-Burning Principle. data relating to total and unit costs of buildings of this type, see Chapter II, pages 802 to 810.

rcentages of Cost of Items of Construction in Fire-Proof Buildings

The tables † on the following six pages show, on pages 1620 to 1625, the ISION OF THE COSTS of fire-proof buildings among the different materials and ts of the construction, the data having been furnished the compiler by hitects and builders in the cities mentioned in the tables. Each column of ues in the tables gives the data for an individual building, except the values New York City, in the second, third and fifth columns, which show the rages for a large number of buildings. The tables on the first four pages lude only buildings approximating closely the standard specifications of the tional Board of Fire Underwriters. The tables show that the foundations l steel frames, the only parts little damaged in conflagrations, represent, proximately, only 25% of the entire sound value of a building. For example, the tables on the first four pages, the average cost of all the foundations is , while the average cost of the steel frames is 17.88%. The tables show, o, on pages 1624 and 1625 the percentages of cost of the classified items of nstruction of eight buildings damaged by the Baltimore conflagration (1904), averages of these eight buildings being given in the last column.

* See "Comparative Costs of Reinforced Concrete Buildings," by E. G. Perrot, in oceedings of the National Association of Cement Users, Vol. V, 1909. See, also, notes costs on page 1614.

† The tables on the first four pages were compiled by F. J. T. Stewart, Continental surance Company, and those on the last two pages by the Baltimore Committee of e National Board of Fire Underwriters. All are reproduced, by permission, from J. K. eitag's Fire Prevention and Fire Protection. Those parts of the Baltimore tables ich gave the proportion of fire-damage to sound value of the various items have been nitted as this article of the Pocket-Book deals more especially with original costs.

Costs * of Different Kinds of Work per Cubic Foot of Building

Some estimates † have been made by F. W. Fitzpatrick showing the prop tionate COST OF THE DIFFERENT BRANCHES OF WORK which go to make up completed building. Believing that these data will be found useful in mak up approximate estimates, Mr. Kidder obtained permission to use them in th Pocket-Book. The following figures represent the actual cost of a TEN-STO OFFICE-BUILDING, 60 by 130 ft in plan, built in the Middle West, a first-cl fire-proof structure, with two street-fronts faced with granite and resting on pile foundation.

Kind of work	Per cubic foot of entire building, cents	Kind of work	Per cubic foot of entire building, cents
Foundations	1 3/4	Heating	1 1/3
Steel framing	2 1/2	Plumbing	1/2
Granite and all masonry	11 1/6	Elevators	1
Cornice, roofs and sky-lights	2/3	Stairs, scenic structural framing, "making ends meet," lamp-fixtures, etc. What might be called a fair amount for "contingencies" in such a building, including lesser items not mentioned here but grouped together	4 23/30
Fire-proof floors	2/3	Architect's fee	1 2/3
Partitions, tile	2/5		
All plastering and stucco	1 1/4		
Elevator-fronts and all ornamental metalwork	2		
Marble work	3 1/6		
Hardware	2/15		
Joiners' work	1 1/6		
Glass	5/12		
Painting and varnishing	7/30		
Electric wiring	2/5	Total	34 5/12

The Chicago post-office building, containing 12 000 000 cu ft and of mon mental character and finish, cost,* in some of its items, as follows:

Kind of work	Per cubic foot of entire building, cents	Kind of work	Per cubic foot of entire building, cents
Foundations	1 3/4	Ornamental metalwork	2 1/4
Steel framing	2 1/2	Marble	5 2/3
Granite and masonry	13 1/2	Plumbing	1/2
Fire-proof floors	2/3	Heating	1 1/4
Plaster, plain and ornamental	1 7/8		

It will be noticed that the relative cost of several of these items is the sam as in the office-building. The total cost * of this building was 42 1/4 cts per cu f

* These pre-war figures must be increased from 50% to 100%.
† [illegible] in "Fireproof," March, 1903.

Cost * of Buildings per Square Foot

One-Story Buildings of Large Area, such as exposition-buildings, etc., may be estimated almost as accurately by the square foot of ground covered as by the cubic foot of building, as there are few or no interior partitions, and usually no plastering or interior finish.

Iron and Steel Buildings. "Roughly speaking, the cost of one-story iron and steel buildings, complete, is, for sheds and storage-houses, from 40 to 60 cts per sq ft of ground, and for such buildings as machine-shops, foundries, and electric-light plants, that are provided with traveling cranes, the cost is from 60 to 90 cts per sq ft of ground covered." †

Structural Steel. For estimates of cost of structural steel for buildings, see pages 1204 to 1207.

Wooden and Brick Mills and Warehouses. See Chapter XXII, pages to 810.

Exposition-Buildings. The cost ‡ of the World's Fair buildings (Chicago, 1893) per square foot of ground covered, including sculpture and decoration, as follows:

Manufactures and Liberal Arts Building	$1.39
Transportation Building	1.08
Electricity Building	1.69
Machinery Hall	2.12
Agricultural Building	1.44
Administration Building	9.18
Horticultural Building	1.41
Mines and Mining Building	1.04
Fisheries Building	2.35
Forestry Building	0.75

Cost * of Structures for the St. Louis Exposition (1904). The following figures were issued by Isaac S. Taylor, at that time Director of Works, of the

Building	Dimensions, ft	Area, acres	Total cost	Cost, sq ft
Art	161×346	1.42	$967 833.90	$5.45
Two Art Pavilions, each	144×423	3.14		
Art Building Annex	106×150	0.41	39 388.99	2.48
Government Building	200×736	3.86	328 980.00	2.23
Government Fisheries	136×136	0.42	45 000.00	2.43
Mines and Metallurgy	525×750	9.08	488 848.50	1.24
Liberal Arts	525×750	8.80	471 820.95	1.20
Education and Social Economy	525×758	7.70	323 950.75	0.81
Manufactures	525×1 200	13.47	711 510.00	1.13
Electricity	525×758	6.67	408 531.57	1.03
Varied Industries	525×1 200	10.28	704 067.96	1.12
Machinery	525×1 000	9.48	509 110.50	0.97
Steam, Gas and Fuel	301×326½	2.25	135 480.00	1.38
Transportation	525×1 300	15.70	674 853.42	0.99
Horticulture	374×782	5.42	225 342.27	0.77
Agriculture	500×1 600	18.62	520 491.07	0.58
Forestry, Fish and Game	300×600	4.07	168 883.38	0.94
Festival Hall	195 in diameter, exclusive of annex	1.09	215 899.00	....

* These pre-war prices must be increased from 50% to 100%. † H. G. Tyrell.
‡ Given by E. C. Chankland, chief engineer.

World's Fair, showing the area and cost of the principal exhibition-bu[illegible] The total area of twenty-two buildings was 123.51 acres, and the to[illegible] $6 939 992.26. The cost was for the bare buildings, and did not include[illegible] tural or other decorations, or the architects' compensation.

Recent Exposition Buildings. The cost of buildings of this c[illegible] erected since 1904, shows a pretty general increase up to 1914, with oc[illegible] variations in the rate of change, of from 1 to 2% per year. Increase si[illegible] would be from 50 to 100%.

Cost * of United States Government Buildings. There was pub[illegible] 1900, by the United States Treasury Department, a history of the [illegible] buildings of the United States, giving their cost, and in 1902, there w[illegible] lished † a list of 287 buildings, giving the cost per cubic foot, the m[illegible] used for the walls and the date of erection. There was also published, in 1[illegible] by the Committee on Public Buildings and Grounds of the United States Se[illegible] a list of sites and plans for public buildings, giving data of much value in [illegible] to the cost of public buildings, their cubical contents and their cost per c[illegible] foot, including buildings erected from 1816 to 1910. "As a rule, these bu[illegible] have cost more per cubic foot than private buildings, so that their cost ca[illegible] always be used as a guide, except for government buildings." ‡

Unit Prices * per Cubic Foot for Recent Government Buildings of [illegible] Same Type.§ The data included in the following paragraphs relate to [illegible] buildings erected before or in process of construction in 1914. They a[illegible] certain FIXED TYPES and in different parts of the United States. The bu[illegible] are post-office buildings and the location, brief description of the general c[illegible] struction, ground-area covered, cubical contents and comparative rates [illegible] cubic foot are given. The buildings are grouped under five different types [illegible] the VARIATIONS IN COSTS PER CUBIC FOOT of similar or identical buildings in [illegible] type, located in different sections of the country, are shown. Following [illegible] five types is a list of buildings of various sizes and descriptions showing [illegible] variations in the cubic-foot rates. The conclusions arrived at and summa[illegible] at the end of the lists, include a table which shows what was considered by [illegible] office of the Supervising Architect to be a fair DIFFERENCE IN COST OF BUIL[illegible] OF THE SAME TYPE in different sections of the United States. It was consid[illegible] also, by that office, that the method of estimating the cost of buildings [illegible] CUBIC-FOOT UNIT PRICE is productive of very uncertain results, inasmuc[illegible] there are many variable conditions entering into the construction of buil[illegible] located in different localities. The principal items affecting the cost of si[illegible] types of buildings are:

(1) Labor; rates and efficiency.

(2) Materials; quality and freight-rates.

(3) Season; time of year when building is constructed.

(4) Contractors; finances, ability, equipment, overhead expenses and ra[illegible] of profit desired.

* Pre-war figures must be increased from 50% to 100%.

† Published in the Architects' and Builders' Magazine, Aug., 1902, and in the In[illegible] Architect, April, 1902.

‡ F. E. Kidder, in previous editions of the Pocket-Book.

§ The information relating to the cost of recent government buildings of certain [illegible] was furnished by J. W. Ginder, Superintendent of the Computing Division, Of[illegible] the Supervising Architect, by permission of Mr. O. Wenderoth, the Supervising A[illegible] tect, through whose courtesy and valuable assistance the editor is able to present [illegible] data referred to. The editor regrets that limited space prevents the reproduction [illegible] carefully prepared and most interesting series of photographs of the plans, eleva[illegible] and sections of the government buildings, the costs of which per cubic foot are discussed.

:) Location; as to supply-centers, distance from railroads, and facilities for dling mtaerials.

'ariations in Unit Costs * of Identical Buildings in Different Localities

order to compare the costs of identical buildings, with slight modification ', the following are given as examples, to show the variance in different lities.

ype 1. Post-office buildings at Grenada, Miss., Bennettsville, S. C., Covon, Tenn., and Burlington, N. J.

escription. Main building, two stories and basement; rear projection, one y and basement; non-fire-proof construction throughout; brick facing; stone ; wooden cornice; slate-covered gable roof, with dormers over two-story ion, and flat, composition roof over one-story portion.

Area and contents	
round-area	3 825 sq ft
ubical contents	138 210 cu ft

Rate per cubic foot *		
Location	Non-fire-proof	First floor, fire-proof
renada, Miss	$0.322	$0.327
ovington, Tenn.	0.315	0.324
ennettsville, S. C.	0.304	0.309
urlington, N. J.	0.293	0.298

ype 2. Post-office buildings at Winchester, Tenn., McPherson, Kan., and ngview, Tex.

Description. Main building, two stories; rear projection, one story; partly avated basement; non-fire-proof construction throughout; brick facing; ne trim; wooden cornice and pilasters at front entrance; slate-covered gable f with dormers over two-story portion, and flat, composition roof over onery portion.

Area and contents	
round-area	3 825 sq ft
ubical contents	138 210 cu ft

Rate per cubic foot *		
Location	Non-fire-proof	First floor, fire-proof
Vinchester, Tenn.	$0.344	$0.350
IcPherson, Kan.	0.346	0.351
ongview, Tex	0.332	0.337

* These pre-war figures must be increased from 50 to 100%.

Type 3. Post-office buildings at Cookeville, Tenn., and Jackson, Ky.

Description. Three-story-and-basement building; stone-faced to top course over water-table; selected, common-brick facing and ornamental terra-cotta trim; composition and slate roof and non-fire-proof construction, except the first floor.

Area and contents	
Ground-area	4 942 sq ft
Cubical contents	290 300 cu ft
Rate per cubic foot *	
Cookeville, Tenn	$0.275
Jackson, Ky	0.269

Type 4. Post-office buildings at Garden City, Kan., and Lake City, Minn. (identical buildings).

Description. One-story-and-basement, brick-faced building, with stone water-table course and trimmings and ornamental terra-cotta cornice, architrave and parapet-coping; non-fire-proof construction, except the first floor; composition roof.

Area and contents	
Ground-area	3 888 sq ft
Cubical contents	141 456 cu ft
Rate per cubic foot *	
Garden City, Kan	$0.405
Lake City, Minn	0.341

Type 5. Post-office buildings at Abilene, Kan., and Bellefontaine, Ohio.

Description. One story and basement; stone facing; granite steps, etc.; tin roof; fire-proof construction, except roof.

Area and contents	
Ground-area	5 000 sq ft
Cubical contents	183 000 cu ft
Rate per cubic foot *	
Abilene, Kan	$0.359
Bellefontaine, Ohio	0.367

Buildings of Various Sizes and Descriptions. The following list is of buildings of various sizes and descriptions throughout the country and shows the variance in the cubic-foot rate.

* These pre-war figures must be increased from 50 to 100%.

ost-office building at New Rochelle, N. Y.

escription. This building is of an irregular plan; two-story and basement; er pavilion; sides and rear one-story and basement; clearstory over work-n; stone facing to first-floor level; brick facing above this point, with terra-a trim and cornice; composition roof; fire-proof construction.

Ground-area	7 512 sq ft
Cubical contents	258 900 cu ft
Rate per cubic foot *	$0.259

ost-office building at Mobile, Ala.

escription. Front portion, two stories, and rear portion, one story over kroom. Only a small portion of basement excavated for heating-plant. n building faced with limestone and rear second story portion with orna-tal terra-cotta. Fire-proof construction; long and short spans, and con-e joists with terra-cotta fillers; copper deck and Spanish-tile roofs.

Ground-area	18 054 sq ft
Cubical contents	670 476 cu ft
Rate per cubic foot *	$0.341

ost-office building at Muskogee, Okla.

escription. A four-story-and-basement building. Granite to the first-line, stone-faced above (except in interior court, which is brick); terra-a cresting at roof; copper roofing and fire-proof construction throughout. n standard types of concrete and terra-cotta floor-construction. Monu-tal in design. Corinthian colonnade at entrance. Eight heavy bronze -standards. Six flights of marble stairs. Entire lobby of marble, and ornamental plaster-work in lobby and court-room.

Ground-area	20 400 sq ft
Cubical contents	1 326 612 cu ft
Rate per cubic foot *	$0.43

ost-office building at New Bedford, Mass.

escription. One story, basement and mezzanine with clearstory over ral portion; granite facing, except clearstory, which is faced with terra-a; main roof of composition; clearstory roof of copper; fire-proof con-ction.

Ground-area	27 750 sq ft
Cubical contents	1 080 690 cu ft
Rate per cubic foot *	$0.323

ost-office building at Newark, Ohio.

escription. Two-story, basement and unfinished attic. The workroom ex-s through two stories. Offices in second story over balance of building. proof construction throughout. Terra-cotta floors, ceilings, roofs, parti-, furring, etc. Exterior faced with pink granite to the first-floor level and white marble above, including cornice, parapet, etc. Flat tin roof; bronze s at first and second-story windows on front of building. Cast-iron grilles rst-story and basement-windows on sides and rear; bronze-faced post-screens, desks, revolving doors, vestibules, etc., and drawn-bronze covered s, window-frames, doors, etc., in lobby. Caen-stone cornice and coffered g in lobby. Bronze and marble stairs to second story.

* These pre-war figures must be increased from 50 to 100%.

Ground-area	6 912 sq ft
Cubical contents	369 640 cu ft
Rate per cubic foot *	$0.487

Post-office building at Minot, N. D.

Description. Three-story-and-basement building; fire-proof, except r which is plank on steel beams; stone facing to second-story window-sills; b facing above, with stone cornice, parapet-coping, etc.

Ground-area	6 700 sq ft
Cubical contents	427 300 cu ft
Rate per cubic foot *	$0.328

Post-office building at McAlester, Okla.

Description. Three stories and basement; fire-proof, except roof; te cotta floors, etc.; suspended ceilings; stone facing to second-floor level; b facing above, with stone trim; cornice and balustrade; tin roof.

Ground-area	7 482 sq ft
Cubical contents	394 765 cu ft
Rate per cubic foot *	$0.38

Post-office building at North Tonawanda, N. Y.

Description. The building has two stories and basement; granite to first-floor line; brick-faced above with stone trimming and slate roof; fire-p construction to and including the second floor.

Ground-area	5 475 sq ft
Cubical contents	276 320 cu ft
Rate per cubic foot *	$0.289

Conclusions Regarding Variations in Unit Costs. In the foreg unit costs, the APPROACH-WORK, such as walks, platforms, terraces, etc., is cluded. This, in some cases, is quite expensive, and is generally from 5 to of the entire cost of the building. In federal buildings, there are many requ ments not met with in the ordinary mercantile buildings, and the perma character of the building necessitates all materials, workmanship and const tion to be of the very best in each case. This is guaranteed by iron-clad sp fications, long-time guarantees for several items of the work, and pers government inspection. The office of the supervising architect has de mined that the RELATIVE INCREASE in cost of buildings throughout the cou over the cost in the Mississippi Valley district was about as follows, taking Mississippi Valley district, as a BASE, at 100%, and the labor and market-c ditions which prevailed in October, 1914.

	Per cent
Mississippi Valley district	100
New England (except Maine)	110
Maine	115
Southern States	100
Northwest Mountain district	130
Southwest Mountain district	120
Pacific Coast	125

* These pre-war figures must be increased from 50 to 100%.

In the grouping of districts, the Mississippi Valley district is intended to ver the Middle States as far east as Ohio and Pennsylvania, and the states, erally, bordering on the western bank of the Mississippi River. This is nd to be a part of the country in which the LOWEST PRICES have been obned. The other districts represent the approximate greater cost for buildings r that in the Mississippi Valley or Middle States, and is intended to repret the DIFFERENCE IN COST AT ANY TIME; but is not intended to represent difference in cost at different periods.

Illustration of Variation in Cost * of Buildings of Identical Area and ntents. The following notes are taken from photographs of drawings and n data accompanying them.† The drawings were for a Post-Office build- at Menomonie, Wis. This building contains 4 770 sq ft of ground-area, the cubical contents are 147 570 cu ft. The contract was awarded (1913) $45 380, or at the rate of $0.308 per cu ft. It is a one-story-and-basement lding, faced with brick, with stone water-table, brick parapet and tin and iposition roof. The first floor, only, is fire-proof. Proposals were opened 14) for a Post-Office building at Uvalde, Tex. This building, except for e slight modifications, is as nearly like the Menomonie building as it is sible to make it without using the same drawings. The ground-area of the lde building is 4 672 sq ft and the cubical contents, 151 875 cu ft. The work onnection with the approaches is practically the same as that at Menomonie. hese buildings had been erected in the same town, it does not appear that re would have been any difference in the costs, but the lowest proposal ived for the Uvalde building was $56 400, or at the rate of $0.371 per cu ft. omparison of the amounts for these two buildings further illustrates the eliability of any universal application of the cubic-foot rate in determining costs of buildings, and also shows that the difference in cost of construction uildings in different sections of the country varies considerably.

ost per Cubic Foot of Some Important Federal Buildings. The follow- tabulations contain additional unit costs and other data for public buildings.

Cost * per Cubic Foot of Some Important Federal Buildings.

Location and building	Cost per cubic foot, cents *
w York, N. Y., Custom-House (completed 1908)	74
eveland, Ohio, Post-Office, Custom-House and Court-House	68

Depreciation of Buildings ‡

Discounts from Values of New Buildings. The figures given on the preceding pages are for new buildings. To ascertain their value at any time subsequent to their erection, a discount from the value when new should be made as follows:

	Per cent per year
Brick, occupied by owner	1 to 1¼
Brick, occupied by tenant	1¼ to 1½
Frame, occupied by owner	2 to 2½
Frame, occupied by tenant	2½ to 3

If built of long-leaf yellow pine, or of spruce from the New England States, add from 20 to 30%, or if of short-leaf yellow pine, add from 40 to 50% to the values. If of redwood or cedar from the Pacific Coast, use about one-half these estimates, which are for white pine or white pine with oak framing-timbers. These figures for depreciation are to include buildings in which ordinary repairs have been made. If extraordinary repairs have been made, the discount should not be so heavy. Good judgment must be used in estimating the amount of depreciation in buildings.

The Depreciation of Mill-Buildings. The annual depreciation of a mill-building of slow-burning construction varies from 1 to 1½%, while the depreciation of a reinforced-concrete factory-building is relatively much less, since it is confined entirely to such details as windows, doors, roofing, etc.

The Wear and Tear of Building Materials. At the tenth annual meeting of the Fire Underwriters' Association of the Northwest, held at Chicago, September, 1879, Mr. A. W. Spalding read a paper on the wear and tear of building materials and tabulated the results of his investigations in the following form:

* These pre-war figures must be increased from 50 to 100%.

† Reproduced, by permission, from the Journal of the Society of Constructors of Federal Buildings, September, 1914, through the courtesy of C. R. Marsh, Editor Publications of the Society of Constructors of Federal Buildings. This Journal, published monthly, contains data of much interest to architects and builders.

'hese figures represent the averages deduced from the replies made by eighty-ee competent builders unconnected with fire-insurance companies in twenty-en cities and towns of the eleven Western States.

THE QUANTITY SYSTEM *

:xplanation of the System. The QUANTITY SYSTEM is not, as some persons e supposed, merely the taking off of a list of items by one person probably h uncertain accuracy, for some other person's use. It means the careful isurement by a disinterested expert specially trained in this kind of work, t is, a QUANTITY SURVEYOR. This specialist proceeds in a manner quite erent from that of the average contractor. He follows a certain recognized er and system in taking off quantities, abstracting and billing, with a view liminating errors. He uses certain uniform standards of measurements and ressions well understood by bidders. His checking and rechecking methods ensure accuracy must be studied to be appreciated by those to whom the ntity system is unknown. A record is kept of every item, however small, ing a money-value. These items are classified and arranged, each under proper trade or department, in methodical order. Guess-work methods

The quantity "system" which is not merely a survey of items, has been systematically ocated since 1891 by G. Alexander Wright, A.I.A., 354 Pine Street, San Francisco, is the founder of the movement to adapt the Quantity System to American building tice. It has attracted much attention among contractors, architects, and engineers. ourse of time this system of estimating must be adopted, as it stands for a square between owner and contractor. The movement in aid of this work is purely a ntary one, an honest effort to bring about better methods.

are unknown to the quantity surveyor, while his accuracy and attention to small details is worthy of comment. Every bidder figures from a copy of the surveyor's quantities furnished to each one, with (if desired) the plans and specifications. The surveyor who does this work is a professional man similar to the engineer or the architect. He should, in fact, have, and he usually has had, experience in these professions, and in addition, a practical experience acquired in the field in actual contact with and superintendence of construction work.

Method of Procedure. Such a surveyor, in taking off quantities from the architect's or engineer's drawings, readily detects any discrepancies due to hasty preparation or other cause. The attention of the architect or engineer is called to such matters by the quantity surveyor, as he goes on with his work. Detected in this way, all uncertainties are at once corrected and adjusted, so that by the time the drawings and specifications reach contractors, everything has been made plain and accurate and the possibility of error in quantities can therefore be disregarded. The resulting document, the BILL OF QUANTITIES is then either printed or otherwise reproduced, and a facsimile copy supplied free of cost to each bidder who inserts his unit price opposite each item and in an hour or two foots up the money-cost in dollars and cents. This is really all that a contractor should be expected to do (for nothing). The BILL OF QUANTITIES contains everything the contractor is called upon to perform or furnish, in order to complete his contract. In short, the bid becomes a proposal to do a certain FIXED QUANTITY of work, no more and no less. This then, briefly, is the main underlying principle of the QUANTITY SYSTEM: a definite quantity of work for a definite price, and the elimination of every condition which now compels bidders to take chances.

The Present Unsatisfactory Conditions. Most architects are familiar with the wasteful, unsatisfactory methods followed to-day. They injure both parties to a contract because of bidders' mistakes in figuring, accuracy being so often sacrificed for speed. While wonderful strides in methods of construction have been made, no attention has been given to STANDARDIZING METHODS of measuring builders' work, and so both owner and contractor suffer. As a result of the movement in aid of better methods (initiated in San Francisco in 1891) more conservatism, and a closer adherence to business principles is being preferred in place of gambling methods of estimating. Architects and engineers who now permit an unduly low bidder to take a contract are courting trouble every time.

Use of the Quantity System in Other Countries. The principle of payment by measurement is based upon equity and square dealing. On large work it is used in England, Ireland, Scotland, France, Germany, Australia, and South Africa, and to some extent in the United States and Canada. It is a significant fact, that in no instance in which this measurement system has been once established, has it ever been abandoned for the former haphazard methods.

Advantages Claimed for the Quantity System. The following are the advantages claimed for the system:

(1) An immense saving of time and money now wasted by bidders, all doing the same thing, going over the same ground, and each arriving at a different result.

(2) Safer bids, as the work to be performed is clearly written out in the bill of quantities, which can be the essence of the contract.

(3) No expense to the bidder; the owner pays for the quantities knowingly, ie owners pay now, but this fact is not brought to their attention, and it es not occur to them. The percentage added to a bidder's net cost is not profit, a certain portion being absorbed in overhead charges, including cost estimating, which, of course, is ultimately borne by owners.

(4) Saving of disputes arising from ambiguities, oversights, and even errors, causing extra claims more or less just, but usually vexatious, and sometimes ibarrassing.

(5) Better opportunities for the competent bidder, as the bidders all work and price from the same basis.

(6) Better work and greater harmony. If no part of the work is omitted ere is less reason to skin the work, a proceeding which produces friction, or irse.

(7) Misunderstandings are reduced. The bill of quantities states clearly iat is intended, and is a sort of clearing-house for the drawings and specifica-ns.

(8) Neither party can obtain an advantage over the other on quantity or scription of work.

(9) No disputes with subbidders, it being clearly stated what each trade is furnish.

(10) Contractors have no figuring of quantities to do and can therefore vote more time to buildings in hand and save profits now lost for want of eir personal supervision.

(11) Fewer inferior contractors as lowest bidders.

(12) Fewer extras, which are usually a trouble to all concerned.

(13) The architect or engineer has the assistance by collaboration of the ofessional quantity surveyor, who is available, also, for preliminary figures. is advance-information, now so often furnished by a prospective bidder, eates undesirable obligations.

(14) No change or reorganizing of architects' offices is entailed. Much tail-work now involved in receiving bids could be taken care of in the antity surveyor's office.

(15) The drawings and specifications having been previously made as com-te as possible, subsequent inconvenience to contractors and foremen on the , and inquiries at the architects' offices for explanations become unneces-y. The BILL OF QUANTITIES gives detailed information which cannot be well en by drawings.

Adaptation to American Practice. In the United States any such uni-rsal system must conform to American needs and sentiment, and be a prac-al system. For many reasons it would be unpractical to follow the English ctice. The principles it stands for can, however, be accepted and applied ywhere with great advantage.

IMENSIONS AND DATA USEFUL IN THE PREPARA-TION OF ARCHITECTS' DRAWINGS AND SPECIFICATIONS*

Dimensions for Furniture. For the convenience of draughtsmen when igning furniture or providing space for a special article the following dimen-ns are given: †

* See, also, the additional tables with more detailed and classified lists.

† Many of these dimensions were first contributed to the American Architect of No-nber 10, 1894, by Alvin C. Nye.

Chairs and Seats. The average figures taken from a variety of good ch are: Height of the seat above the floor, 18 in; depth of the seat, 19 in; the h of the back above the floor, 38 in. Usually the seat increases in depth a decreases in height, while the back is higher and slopes more. Twenty inch inside is a comfortable depth for a seat of moderate size. Chair-arms are ab 9 in above the seat. The slope of the back should not be more than one-t the depth of the seat. A LOUNGE is 6 ft long and about 30 in wide.

Tables vary in shape and size almost as much as chairs. Writing-tables a dining-tables are made 2 ft 5 in high, and the type of sideboard called a CARD TABLE is made 3 ft high to the principal shelf; but tables for general use are 2 6 in high. DINING-TABLES are made from 3 ft 6 in to 4 ft wide and to ext from 12 ft to 16 ft by means of slides within the frame. This frame should n be so deep as to interfere with the knees of any one sitting at the table; that i there must be about 2 ft clear space between it and the floor. The smallest s practicable for the KNEE-HOLES of desks and library-tables is 2 ft high by 1 ft 8 wide, the width to be increased as much as possible.

Bedsteads are classed as SINGLE, THREE-QUARTERS, and DOUBLE. A sing bed is from 3 to 4 ft wide inside; a three-quarter bed, from 4 ft to 4 ft 6 i a double bed, 5 ft. Bedsteads are from 6 ft 6 in to 6 ft 8 in long inside. Fo boards are from 2 ft 6 in to 3 ft 6 in and headboards from 5 ft to 6 ft 6 in hig Single beds for dormitories are often made only 2 ft 8 in wide.

Bureaus vary in shape and size to such an extent that it is almost impossi to say that any dimension is fixed. Convenient sizes are: body, 3 ft 5 in wid 1 ft 6 in deep and 2 ft 6 in high; or 4 ft wide, 1 ft 8 in deep and 3 ft high.

Commodes are 1 ft 6 in square on the top and 2 ft 6 in high.

Chiffoniers are about 3 ft wide, 1 ft 8 in deep and 4 ft 4 in high.

Cheval-Glasses are made, if large, 6 ft 4 in high and 3 ft 2 in wide. If smal 5 ft high and 1 ft 8 in wide. If medium, 5 ft 6 in high and 2 ft wide.

Wash-Stands of large sizes are 3 ft long, 1 ft 6 in wide and 2 ft 7 in high. Sma sizes are from 2 ft 4 in to 2 ft 8 in long.

Wardrobes may be 8 ft high, 2 ft deep and 4 ft 6 in wide; or 6 ft 9 in hig 1 ft 5 in deep and 3 ft wide.

Sideboards may be from 4 to 6 ft long and from 20 in to 2 ft 2 in deep.

Upright Pianos vary from 4 ft 10 in to 5 ft 6 in in length, from 4 to 4 ft 9 i in height and are about 2 ft 4 in deep over all.

Miniature and Baby-Grand Pianos vary from 5 ft 10 in to 6 ft in length, a are about 4 ft 10 in in width.

Parlor-Grand Pianos vary from 5½ ft to 6 ft 10 in in length, and are abo 4 ft 10 in in width.

Concert-Grand Pianos are about 8 ft 10 in in length and 5 ft in width.

Billiard-Tables (Collender), 4 by 8 ft, 4 ft 2 in by 9 ft and 5 by 10 ft. Si of room required 13 by 17 ft, 14 by 18 ft and 15 by 20 ft, respectively.

Classified Tables * of Furniture-Dimensions. The following more d tailed and classified tables of average dimensions of furniture are added to tho already given and are taken from recent data furnished by manufacturers

* These additional tables were compiled by E. S. Hand, and much of this data in t several editions of the Pocket-Book has been taken, by permission, from the valuabl treatise on Furniture Designing and Draughting, by A. C. Nye.

rniture. While some of these measurements vary slightly from the dimen ons given in the preceding paragraphs they represent average dimensions o rniture as made at the present time.

Dimensions of Tables

Kind of table	Length	Width	Height	Remarks
Bedroom-table	31	22	29	....
Bedroom-table	18	18	30	Commode

Commode	16	16	31	....
Sideboard	84	32	30	....
Wardrobe	36	19	69	....
Wardrobe	54	24	96	....

All dimensions are in inches. Heights are from the floor. The slope of the back is measured at the seat-level to a perpendicular through the highest point of the back.

Dimensions of Bedsteads

Kind of bed	Inside		Heights		Width, side rail	Height bottom of side rail
	Length	Width	Foot	Head		
Single bed	78	42	40	62	9½	9½
Single bed	78	42	41	60	10	10
Double bed	78	58½	42	63	11	10½
Double bed	78	56	36	67	13	9½

All dimensions are in inches. Heights are from the floor.

Dimensions of Plumbing-Fixtures. Enameled-Iron Bath-Tubs. Standard sizes for roll-rim baths with sloping ends are: nominal lengths, 4 ft, 4½ ft, 5 ft, 5½ ft and 6 ft; width over all, from 30 to 34 in. Specially narrow tubs are made from 25 to 29 in wide. The actual length over rim is usually 1 or 2 in more than the nominal length, and 2 in will include an ordinary overflow-pipe.

Wash-Basins. Crockery basins, to go with marble slabs, are made round and oval. Round bowls are made 10, 12, 13, 14 and 16 in in diam, measured from the outside of the rim. Oval bowls, 14 by 17 in, 15 by 19 in and 16 by 21 in. The 12 and 14-in round, and 15 by 19-in oval, are commonly used.

Marble Basin-Slabs may be 20 by 24 in, 20 by 30 in, 22 by 28 in, or 24 by 30 in, the last being a very common size. They can be made any size, to order. They should be 1¼ in thick, countersunk on top, and should have molded edges where exposed.

Corner-Slabs are commonly made 21 by 21 in and 24 by 24 in. Marble backs are usually 8 or 10 in high, and sometimes 12 in.

Enameled-Iron Wash-Basins or Lavatories made in one piece: common sizes are 16 by 20 in, 11 by 14-in basin; 18 by 21-in, 11 by 15 in basin; 18 by 24 in, 12 by 15-in basin; back, 10½ in high. The smallest-sized wash-basin is 13 in wide at the back.

Corner-Basins, 12½ by 12½ in, 12-in round basin; 15 by 15 in, 11 by 14-in basin; 16 by 16 in, 11 by 14-in basin; 19 by 19 in, 11 by 15-in basin. The standard height of wash-basins is 2 ft 6 in from the floor.

Foot-Baths, enameled iron, roll-rim, are 22½ by 19 in; width, including ittings, 1 ft 11 in; height 17 in; depth inside, 11 in.

Seat-Baths, enameled iron, average about 32 in long over fittings, and 27 in wide.

Water-Closets. The dimensions of water-closet bowls vary considerably, he following being about an average: width of bowl over all, 13 in; depth from vall to front of seat, 23 in; height from floor to seat, 17 in; width of seat, from 5 to 16 in. Closets with low-down tanks measure about 28 in from front of eat to wall. The distance from center of outlet-opening to the walls, or the OUGHING-IN dimensions, are given in manufacturers' catalogues, as they vary vith different closets. The smallest space permissible for water-closet compartments, where doors open out, is 2 ft 4 in by 4 ft. If the doors open in, the compartment should be 3 by 5 ft.

Closet-Ranges, used in schools and factories, are made 24, 27 and 30 in, enter to center of partitions. For graded schools, 24 in is ample, and for ctories, 27 in. The range usually occupies a space 28 in in depth, if set against wall.

Urinal-Stalls should be from 24 to 27 in, center to center of partitions; depth partitions, 20 or 22 in; of ends, 2 ft; of bottom slab, 2 ft; height of partitions, om 4 ft 6 in to 5 ft 6 in.

Kitchen-Sinks of cast iron are made in a great variety of sizes, those most mmonly used being 16 by 24 in, 18 by 30 in, 18 by 36 in, 20 by 30 in and 20 by ; 24 by 50 in is the largest size for enameled sinks. The depth inside, for e sizes given, is 6 in. Plain cast-iron sinks are made as large as 32 by 56 in, or by 78 in. Steel sinks are made in all of the above sizes up to 20 by 40 in.

Porcelain Sinks. Common sizes of porcelain sinks are 20 by 30 in, 23 by 36 in d 24 by 42 in.

Cast-Iron Slop-Sinks, common sizes, are 16 by 16 in, 16 by 20 in, 18 by 22 in d 20 by 24 in; 12 in deep.

Copper Pantry-Sinks. Common sizes are 12 by 18 in, 14 by 20 in and 16 by in.

Laundry-Tubs of slate or soapstone are commonly made 2 ft wide over all, d 16 in deep. Lengths over all, two-part tubs, 4 ft and 4 ft 6 in; three-

part tubs, 6 ft, 6 ft 6 in and 7 ft. Earthen and porcelain tubs come separately and are connected as required. The dimensions of each tub are 2 ft or 2 ft 7½ in in length, 2 ft 1½ in in width and 15 in in depth, inside. The length required for two 2-ft tubs is 4 ft 1 in; for three tubs, 6 ft 2 in; and for four tubs 8 ft 3 in. Wolff's roll-rim enameled-iron wash-tubs are 55 in over all, for two tubs, and 82 in for three tubs.

Range-Boilers are 12 in diameter for 30-gal, 14 in for 40-gal, 16 in for 52-gal and 63-gal, 22 in for 100-gal and 120-gal boilers.

Dimensions of Carriages. Covered Buggy (Goddard). Length over all, 14 ft: width, 5 ft; height, 7 ft 4 in. Will turn in space from 14 to 20 ft square, according to skill.

Coupé. Length over all, 18 ft; width, 6 ft; height, 6 ft 6 in.

Buggy (Piano-Box). Length over all, 14 ft; width, 4 ft 10 in.

Landau. Length over all, 19 ft 6 in; width, 6 ft 3 in; height, 6 ft 3 in; length of pole, 8 ft 0 in.

Stanhope Gig, Two Wheels. Length over all, 10 ft 6 in; width, 5 ft 8 in; height, 7 ft 6 in.

Victoria. Length, without pole, 9 ft 6 in; length of pole, 8 ft; width over all, 5 ft 4 in.

Light Brougham. Length, without pole or shaft, 9 to 11 ft; width over all, 5 ft 4 in; height, 6 ft 4 in.

Automobiles. Length, from 11 to 19 (average 16) ft; width, 6 ft; height, 7 ft.

Dimensions and Weight of Fire-Engines. From measurements of different fire-engines belonging to the city of Boston, it was found that the greatest length, including pole, was 22 ft 6 in. The widths varied from 5 ft to 5 ft 11 in, the average height being 8 ft 8 in. The average weight (computed from 9 engines), 8 000 lb; the greatest weight, 9 420 lb and the least, 4 780 lb.

Dimensions and Weight of Hose-Carriages. Extreme length with horse, 19 ft 6 in, without horse, 17 ft 6 in; width, from 5 ft 9 in to 7 ft; height, from 5 ft 8 in to 7 ft; average weight (computed from 11 carriages), 2 943 lb; greatest weight, 3 500; least weight, 2 120.

Dimensions and Weight of Ladder-Wagons. Length of truck, 33 ft; total length, with ladders on, 45 ft; width, 6 ft 2 in; average weight (computed from 12 wagons), 6 660 lb; greatest weight, 8 800; least, 4 350.

Dimensions of Locomotives and Cars. The dimensions of locomotives and freight-cars vary considerably, but the following will cover those in common use:

Locomotives. From 15 ft 4 in to 15 ft 10 in to top of stack from top of rail; extreme width of cab, 10 ft 2 in. Doors to admit locomotives should be from 12 to 13 ft wide and 18 ft high.

Furniture-Cars are 14 ft 1 in, from top of track to top of brake-staff; floor, 3 ft 8 in from track; extreme width, 9 ft 10 in.

Stock-Cars, 13 ft 5 in, from top of track to top of brake-staff; floor, 4 ft from track; extreme width, 9 ft 8 in.

Refrigerator-Cars, 14 ft 6 in, from top of track to top of brake-staff; floor, 4 ft from track; extreme width, 9 ft 7 in.

Ordinary Freight-Cars are about 13 ft high to top of brake-staff and 9 ft 4 in in extreme width. The height of floor of freight-cars varies from 3 ft 8 in to 4 ft above top of track for STANDARD-GAUGE, and from 3 ft to 3 ft 6 in for NARROW-GAUGE cars. Standard-gauge, 4 ft 8½ in.

Passenger-Coaches vary from 14 to 16 ft in height and from 10 to 11 ft in idth. Doors to admit cars should give at least 12 in clearance on each side, d 2 ft overhead.

Street Trolley-Cars are about 8 ft 6 in wide for the car proper, and the steps oject about 8 in. Height from track to top of coach, 11 ft 6 in; the trolley-ind is 18 in higher. The length varies, up to 42 ft. Trucks for a 41 ft 6 in : are about 24 ft apart. Wheel-bases, 4 ft center to center. Radius of short-: curve in Denver, Colo., 35 ft to midway between rails.

The Gauge of a railroad track is the distance between the inner sides of the ids of the two rails. The STANDARD GAUGE is 4 ft 8½ in

Capacity of Freight-Cars. Car-Loads. The capacity of freight-cars, and : minimum car-loads, vary so greatly that no accurate general information ı be given. For heavy freight, 25 tons is an average load; for light freight, m 12 to 15 tons; for household goods, 10 tons is about the minimum; for .e, 15 tons is about a minimum load; for cement, 20 tons. The minimum -load, to obtain car-load rates, varies with different roads, and also with the e made; a low rate is usually made on the basis of a big load. Thirty tons ı good load for heavy freight, and 40 tons is about the maximum, except for cial cars.

Miscellaneous Dimensions. Horse-Stalls. Width, from 3 ft 10 in to 4 ft else 5 ft or over; length, 9 ft. The width should never be between 4 ft and :. as a horse is liable to cast himself.

Dimensions of Standard Bowling-Alleys.* For ONE PAIR OF ALLEYS: Room essary, 83 ft over all; 11 ft 6 in wide, 60 ft from foul-line to head pin, 3 ft pins to back of alley, 4 ft for pin-pit, 8 in deep in front, 6 in in back; alleys, naple flooring, should extend on and beyond the foul-line 12 ft, and then more, making a 16-ft approach to the foul-line for the player to run to deliver ball. For ONE ALLEY: Same length, 83 ft; width, 6 ft 3¼ in; closer dimen-is; beds 42 in, gutters 9 in, division-pieces 2¾ in, ball-return 9¾ in.

dditional room should be provided for the bowlers and spectators as these ensions are for the alleys only.

imensions of Drawings for Patents (United States). 10 by 15 in, with ler-line 1 in inside all around.

* Dimensions furnished by The Brunswick-Balke-Collender Company, New York City.

Dimensions of a Barrel. Diameter of head, 17 in; diameter at bung, 19 length, 28 in; volume, 7 680 cu in.

Miscellaneous Memoranda. Weight of Men and Women. The aver weight per person of twenty thousand men and women weighed at Boston, Ma in 1864, was, men, 141½ lb; women, 124½ lb.

Wooden Flagpoles. For a flagpole, extending from 30 to 60 ft above roof, the following proportions give satisfactory results: The diameter at roof should be 1/60 the height above the roof, and the top diameter one-half lower. To profile the pole, divide the height into quarters; make the diam at the first quarter above the roof, fifteen-sixteenths of the lower diamet at the second quarter, seven-eighths, and at the third quarter, three-quart the lower diameter.*

Steel Flagpoles.† The Department of Education, City of New York, h abandoned the use of wooden flagpoles and is using steel flagpoles. For ordinary building, 60 ft in height above the curb, a pole 43½ ft in height is us which is sufficient for the tackle of a large or post-flag, for the reason that m parapets are very low. Each pole is required to be fitted complete with a ca iron, galvanized, revolving truck, mounted on crucible-steel pins, the cap b neath it, also, being of galvanized iron. The truck is fitted with two 4 bronze sheaves on Tobin-bronze pins, surmounted with an 8-in 20-oz copp ball, acid-cleaned and painted with four coats of the best English weather-pr sizing, and covered with XXXX leaf-gold. One or more field-joints are p mitted in the length of the pole, which are determined according to standa details, the bands being secured to the male tube, and both edges of the in band and the shoe being machine-beveled to insure a perfect fit. The fema tube is drilled and secured to the male shoe with tap-screws of sufficient streng to carry the upper section of the pole, and the ends of the screws are ups The exposed ends of the female tube are chamfered and caulked tight. A sa collar or band, to receive the copper flashing, is secured to the pole and bra just above the roof-lines.

Dimensions of Schoolrooms, Boston Schools.‡ The sizes of the rooms i the Boston school-houses, as adopted by the school board, are, for gramm schools, 28 by 32 ft in plan by 13 ft 6 in in height; for primary schools, 24 l 32 by 12 ft. This accommodates 56 scholars per room, in each grade, allowi 216 cu ft per scholar in the grammar schools, and 165 cu ft in the primary gra A width of 27 ft is very satisfactory for schoolrooms, and is commonly adopt because it permits of the use of 28-ft joists, without waste.

Heights of Blackboards in Schoolrooms.‡ The heights from floor to t of chalk-rail should be about as follows:

For third and fourth grades,	chalk-rail......	2 ft 1 in from floor
For fifth grade,	chalk-rail......	2 ft 2½ in from floor
For sixth grade,	chalk-rail......	2 ft 4 in from floor
For seventh and eighth grades,	chalk-rail......	2 ft 6 in from floor

Slate blackboards are made 3 ft 6 in, 4 ft and 4 ft 6 in high, 4 ft being a v common and satisfactory height.

* The Building Trades Pocketbook.

† From data compiled by E. S. Hand from notes furnished by C. B. J. Snyder, Sup intendent of School Buildings, New York City.

‡ F. E. Kidder, in previous editions.

Sizes of Seats and Desks for Schools and Academies *

Number of desk	Age of scholar (years)	Height of seat or chair (in)	Height of desk (next scholar) (in)	Space occupied by desk and seat (back to back) ft	in
0	16 to 18	16¾	29½	2	9
1	14 to 16	15½	28	2	9
2	12 to 14	15½	27½	2	8
3	10 to 12	14¼	26½	2	7
4	8 to 10	13¼	25½	2	5

6	6 to 7	11½	22½	2	3
7	5 to 6	10½	21	2	2
....	4 to 5	9½	19	2	0

Desks for two scholars are 3 ft 10 in long, and for a single scholar, 2 ft long.
Aisles are from 2 ft to 2 ft 4 in wide, according to age of scholars and size of room.

Additional Data† on School-Houses

Sizes of Rooms. The Department of Education, New York City, has adopted, the dimensions of the schoolrooms, the German standard of 22 by 30 ft in an by 14 ft in height, with unilateral lighting. These dimensions are used for grades of elementary schools, the sittings being on the basis of 15 sq ft of or-space per pupil. Good light cannot be had on desks which are placed at a eater distance from the windows than one and one-half times the height of the of the upper sash from the floor.

* The editor is indebted to T. Z. Talley for the calculations and arrangement of this table.

to use the lower portion. The upper part of the surface is at a height convenient for the use of the teacher, there being much display-work employed in the lower grades. For scholars in grades from the third to the eighth year, inclusive, and for high schools the chalk-rail is placed 2½ ft from the floor and the boards are 3 ft 6 in in height.

Doors and Stairways. Wardrobes should be entered from the classroom only. Classroom-doors should open into the rooms, so as to afford the teacher control in case of panic. All exit-doors should open out. All stairways should be shut off from corridors by means of self-closing doors, which, together with the stairways and the enclosures, should be of fire-proof materials. Stairways should be of sufficient number to permit of the building being vacated within three minutes from the time a signal is given. This can be effected by allowing a linear width of 4 ft for the first 50 persons and 12 in additional for each 50 persons in excess thereof. No stairway is to be less than 4 ft nor more than 5 ft in width. Exits should be planned so as to provide 15 lin ft for the first 50 persons and 6 in additional for each 100 persons in excess thereof. No stairway should have more than 15 steps in any one flight, changes in direction being effected by a square platform and no winders being used. No stair-door or exit-door should open out over a step. Platforms are to be provided for such doors and are to extend at least 1 ft beyond the edge of the door when standing open.

Stairs.* The RISE of a stair is the height from the top of one step to the top of the next. The TOTAL RISE is the height from floor to floor. The RUN is the horizontal distance from the face of one riser to the face of the next. RISERS are the upright boards or other materials forming the faces of the steps, and the TREADS are the horizontal pieces or surfaces on which the feet tread. Treads are usually from 1¼ to 1¾ in wider than the run, on account of the NOSING. The height of an individual riser or the RISE of any stairs is found by dividing the TOTAL RISE by the number of risers. The RUN of the stairs may be fixed at will unless the space is cramped, but to secure a comfortable stair the run must bear a certain relation to the rise.

Rules for Dimensions of Treads and Risers. For ordinary use a rise of from 7 to 7½ in makes a very comfortable flight of stairs. For schools and for stairs used by children the rise should not exceed 6 in. Stairs having a rise greater than 7¾ in are steep. The width of the run should be determined by the height of the rise; the less the rise the greater should be the run, and *vice versa*. Several rules have been given for proportioning the run to the rise:

(1) THE SUM OF THE RISE AND RUN should be equal to from 17 to 17½ in.

(2) THE SUM OF TWO RISERS AND A TREAD should not be less than 24 nor more than 25 in.

(3) THE PRODUCT OF THE RISE AND RUN should not be less than 70 nor more than 75.

These rules apply only to stairs with nosings. Stone stairs without nosings should have at least 12-in treads for adults. (See Tables, pages 1646–7.)

Height of Hand-Rail. In dwellings, hotels, apartments, etc., the height of the rail should be about 2 ft 6 in above the tread, on a line with the face of the riser. For grand staircases the height may be reduced to 2 ft 4 in. On steep stairs the height should be from 2 ft 7 in to 2 ft 9 in. The rail should also be raised over winders. On landings, the height of the rail should be equal to the height of the stair-rail, measured at the center of the tread, the usual height in residences being from 2 ft 8 in to 2 ft 10 in.

* This subject is quite fully treated in Building Construction and Superintendence, Part II, Carpenters' Work, by F. E. Kidder.

Sash-Cords.* Until a few years ago, linen or cotton cord only was used for nnecting weights with the sashes of double-hung windows, and cord is still ore extensively used than either ribbons or chains. For windows of ordinary e a good brand of cord will wear for a long time, and this material will probly never be entirely displaced by metal. "Tests made at the Massachusetts stitute of Technology show that cords wear much longer than chains, though ey have less tensile strength. Cords should be smooth and round, so that each and bears its part of the stress, and well glazed, so that they have a smooth rface and consequently less wear from friction with the wheel of the pulley." has been found that cord can be braided too hard for durability, yet if it is aided so as to be very flexible it may be so soft that it will stretch and cause eat annoyance by permitting the weight to hit the bottom of the weight-box. e architect, however, should always specify the particular BRAND and SIZE cord to be used, and also the diameter of the pulley. Among the leading ands of sash-cord at present are the Samson Spot,† and the Silver Lake A.‡ ese brands are superior to the ordinary braided cords, which are made from erior yarns to meet the jobbers' requirements for price. In addition to other ost excellent qualities, the Samson cord offers an additional advantage that chitects will appreciate; it has a colored strand woven through it, which shows spots on the surface and thus enables one to tell at a glance that no other cord s been substituted. The Silver Lake A sash-cord has the name Silver Lake A anded on every foot of cord; but unless the letter A accompanies the name a cond grade of cord is denoted. The marking of the cord by color, or any ner device, does not alter the quality of the cord. Special marks may be plied to inferior cords as well as to the best. The following numbers should specified for the different weights of sash-weights:

Relative Sizes of Sash-Cords, Weights and Pulleys

ize-number	6	7	8	9	10	12
Diameter in inches	3/16	7/32	1/4	9/32	5/16	3/8
eet per pound	66	55	44	36	27	20
uitable for weights in pounds up to	5	12	20	30	40	50
inimum diameter in inches of pulley allowable	1 1/2	1 3/4	2	2 1/4	2 1/2	3

For hanging sashes weighing over 40 lb, only the largest size of Samson or ver Lake A cord, or some form of sash-chain or sash-ribbon, should be used, d the pulleys should be selected to fit the cord or chain. A guarantee that the d will last at least twenty years may be had from either of the manufacturers ntioned above. The Samson wire-center sash-cord has recently been put on market. This is really a metal sash-cord protected by a braided-cotton sure which acts as a noiseless cushion. It is claimed that it harmonizes with the dow-finish and that it has greater durability than other sash-cords or metal ices. (See record of tests made at Massachusetts Institute of Technology, ge 1651.) The standard color is that of dark mahogany, but this cord is de to order for large buildings in other colors to match the finish.

* The following notes, relating to Sash-Cords, Sash-Chains, Sash-Ribbons, Sashights and Sash-Balances, are condensed and revised from articles by Professor Thomas lan. in Kidder's Building Construction and Superintendence, Part II, Carpenters' rk.
† Manufactured by the Samson Cordage Works, Boston, Mass.
‡ Manufactured by the Silver Lake Company, Boston, Mass.

Sash-Chains. Of several styles of sash-chains on the market, the style most largely used is the flat-link chain.* This chain is made either of steel, or of bronze composed of 95% copper and 5% of tin. For suspending very heavy sashes, doors and gates, a cable-chain has been extensively used. Star † sash-chain is made of bronze-metal. The manufacturers of the Norris sash-pulley claim that a riveted chain that has joints only one way is almost sure to break when even slightly twisted, and that it is better to use two chains of the link-pattern running side by side over the same pulley. The strongest sash-chains are of steel made rust-proof by the hot-galvanizing process, and electro-copperplated to give a bronze finish; and of a bronze-mixture which looks like copper, but tougher and harder. One firm ‡ claims that its galvanized-steel sash-chain is from 11 to 45% stronger than any bronze or copper sash-chain and that it will resist fire for a much longer period. The tensile strength of their chain varies from 475 to 850 lb, according to the weight used.

Sash-Ribbons. These are now also extensively used in hanging the sashes in the better class of buildings. The ribbons are made of steel and aluminum bronze or of some mixture of aluminum, and in 3/8, 1/2, 5/8, 3/4 and 7/8-in widths. They are claimed to be practically indestructible, but according to one series of tests it would appear that in some cases they do not wear as long as sash-cords or sash-chains. Some people object that the ribbons snap against the pulley stiles, when the sash is raised or lowered, and thus make considerable noise. The 3/8-in ribbon may be used for a sash weighing up to 100 lb and requires 50-lb weights. For a window 6 ft 10 in high and 3 ft wide, glazed with plate glass, the ribbons with attachments cost about 75 cts. Sash-ribbons are now manufactured by a number of firms who also make the necessary attachments for weight and sash. For the best working of windows hung with ribbons, pulleys of the following sizes should be used:

For sashes weighing not over	40 lb,	2 in
For sashes weighing not over	60 lb,	2 1/4 in
For sashes weighing not over	100 lb,	2 1/2 in
For sashes weighing not over	150 lb,	3 in
For sashes weighing not over	250 lb,	3 1/2 in
For sashes weighing not over	300 lb,	4 in
For sashes weighing not over	350 lb,	4 1/2 in

Comparative Strength of Sash-Cords and Chains. The comparative strength and durability of sash-cords and chains have been determined by careful tests, but there is a great variation in both cases, due partly to variation in material, but principally to the relative sizes of the chain and pulley or cord and pulley. The cords or chains may be too light for the weights used, or the pulleys too small in diameter to carry the cord without undue bending. The pulleys may also have too narrow a groove or an uneven groove with sharp edges which cut the cords. The larger the diameter of the pulley, the less the wear.

Tests § on Wire-Center Sash-Cord and Bronze Sash-Chains. The cord tested was size No. 8, 1/4-in diam, Samson solid braided cotton cord with a

* One type of this kind of sash-chain is manufactured by the Bridgeport Chain Company, Bridgeport, Conn.

† Manufactured by the U. T. Hungerford Brass & Copper Company, New York City.

‡ The Oneida Community, Ltd., Oneida, N. Y.

§ Made at the Massachusetts Institute of Technology, May, 1914, by Professor Miller.

wire cable center, 1/16 in in diam. The chains tested were of two different makes of bronze, size No. 2, purchased in the open market as typical bronze sash-chains, each recommended by a reputable dealer as the proper chain for use with a 25-lb window-weight. The tests for the better of the two chains are those given. Durability-tests were made by raising and lowering a 25-lb weight over a 2-in pulley, each movement corresponding to once opening and shutting a window. The cord was tested over the regular round grooved pulley ordinarily used for cords, and the chains were tested over the combination grooved pulley usually furnished for sash-chains. For the fire-tests the cords or chains were hung through an asbestos box in which a Bunsen flame under pressure was applied to all alike, the temperature being about 2 200° F. A 25-lb weight was attached in each case to keep the cord or chain under the same tension. The wire-center cord took about twice as long to burn through and wore about seventeen times as long as the bronze chain.

Weights of Sashes and Glass. In figuring the weights of windows, the weight of the glass may be taken at 3½ lb per sq ft for plate glass, 1½ lb for double-strength glass and 1 lb for single-strength glass. For the weight of the wooden sash, add together the height and width, in feet, of each sash, and multiply by 2.1 for 2¼-in sash, by 1⅔ for 1¾-in sash and by 1⅓ for 1⅜-in sash. These values are sufficiently accurate for determining the size of sash-cords and pulleys, but the weights should be determined by weighing each sash after it is glazed, as the weight of the glass varies considerably.

Iron Sash-Weights. The weights ordinarily used for balancing windows are made of cast iron, in the form of solid cylinders from 1⅜ to 2⅛ in in diameter, and from 7½ to 31 in long, with an eye cast in the upper end of each. The lengths vary with the weights, which are from 2 to 25 lb. Flat weights, which usually are called for in the Philadelphia and some other markets, are from 6 to 34½ in long, from 2 to 30 lb in weight, and from 1¼ by 1⅝ to 1⅝ by 2¼ in in cross-section. In ordering sash-weights the number of pounds of each weight, and the sections and lengths of the boxes in which the weights will work, should be given. Ordinary weights have very rough eyes for the sash-cords. There are a few manufacturers in the East who make weights with a patent eye that will

not cut the cord. A sectional sash-weight* made with a well-designed hooking device which has given satisfaction, is said to be one of the best on the market. Usually from three to six sections are required on each side to balance a sash properly. If the hooking-device fails near the top the upper sash cannot be closed and if at the bottom the window cannot be opened. It is then necessary to open the weight-box and rehang the sections before the window can be operated. In theory, sectional weights are ideal; in practice, however, they are not considered as satisfactory as solid weights. The Brown † sectional weights are made 2¼ by 2⅝ in and in weights of 6, 7, 8, 9 and 10 lb. They are made of both cast-iron and lead. It frequently occurs after a contract is let, that the glass is changed from double-thick to plate or prism glass. This means increased weight; but the length of the sash-weight cannot be increased and it, therefore, becomes necessary to increase the area of its cross-section. If the weight-box is detailed to take the regular round sash-weight, its general construction will be such that it will take a 2-in round sash-weight, but not a 2-in square sash-weight. This difficulty can be avoided by a little thought at the start. An added depth of ¼ in in the weight-box permits the use of a rectangular cast-iron sash-weight. The Sanborn sectional sash-weight ‡ is intended for use in large buildings of heavy construction. Because of the lack of uniformity in the weight of plate glass the required weights of sash-weights cannot be accurately determined previous to the hanging of the sashes. By the use of a sectional sash-weight, combinations of units can be made up to suit the requirements. The units are made square or rectangular in section in order to secure a maximum weight with a minimum length. An opening of 12 in in the side of the pocket is sufficient for hanging the largest unit. These units are manufactured in standard sizes to meet the general conditions found in the building trades.

Lead Sash-Weights. It often happens that for wide and low windows the weights if of iron would be so long that they would touch the bottom of the pocket before the bottom sash was fully raised. In such cases lead weights are usually resorted to, lead being 80% heavier than cast iron. By casting the weights square in section, whether of iron or lead, a considerable saving can be made in the lengths. One sash-weight manufacturer § makes a specialty of compressed-lead sash-weights, with wrought and malleable-iron fastenings centered so that the weights hang perfectly plumb; and when lead weights are necessary the architect will do well to specify the weights made by this company. These weights are made under hydraulic pressure, by which greater smoothness, solidity and density of metal is secured than is possible by the casting-process. A wrought-iron rod is run through the center, to which are securely attached the malleable-iron fittings. In hanging the sashes the weights for the upper sash should be about ½ lb heavier than the sash, and for the lower sash, ½ lb lighter.

Sash-Balances. Within a comparatively few years several devices have been patented for balancing sashes by means of springs instead of weights, but the author believes that only one type, known as the SASH-BALANCE, has proved a practical success. The sash-balance consists of a drum on which the ribbon is wound, and which contains a coiled-steel clock-spring, immersed in oil; the spring sustains the weight of the sash. The common type very much resembles in outward appearance the ordinary sash-pulley, and is applied in practically the same way; the ribbons, which are made usually of aluminum-bronze, are

§ Raymond Lead Works, Chicago, Ill.

ached to the sashes in the same manner as cords when weights are used. ile the sash-balance in its best form works very satisfactorily, it will probably er entirely supplant the weight and axle-pulley for ordinary windows. There many windows, however, for which sufficient pocket-room for weights cannot obtained without spoiling the effect desired or narrowing the glass, as in some windows, or where it is undesirable to break the frame into the brick jamb. such cases the sash-balance is almost invaluable. For hanging the glass rs of show-cases, sash-balances are usually preferable to weights. Sash-ances are made in both side and top-patterns, but the former are recommended erever there is room at the side of the frame for the depth of mortise required. windows of the sizes usually found in residences, the depth of the sash-ance measured from the face of the pulley-stile will vary from 3 to 4 in; s can be provided for usually by cutting a hole, if necessary, in the masonry studding back of the frame. As sash-balances require only a plank frame, consequent reduction in the cost of the frame offsets the extra cost of the ance. In remodeling old buildings which have plank frames without weights, h-balances are found to be a great convenience, since they can easily be in-ted in the old frames. An advantage which all spring-balances possess is t they act most strongly when the sash is down, and so enable one to raise inding window more readily than if it were hung with weights; while when sash is up the springs barely suffice to hold it in position, and do not offer stance to drawing it down. Of the various sash-balances on the market, the lman * and the Caldwell † are the most extensively used, and are undoubtedly able. The Pullman Unit sash-balance has been on the market many years l has proved satisfactory. These balances are now made with uniform-size e-plates for the various weights of sash with which they are to be used, and s make it possible to have all mortises for the balances cut at the mill, as is v done for the regular cord-pulleys. The Caldwell sash-balance, both top l side-types, is much used by the United States Post Office and Navy Depart-nts. It is used also by the leading car-builders. The springs are made of h-grade cold-rolled tempered-steel wire, a material similar to that used for k-springs. The manufacturers guarantee these sash-balances for from ten ifteen years.

Seating-Space in Churches and Theaters. The minimum spacing for rs, back to back, is 30 in. This spacing is fairly comfortable for occupants, is a little cramped for persons passing by others into or out of the pews. pacing of 32 in is to be preferred, and if there is abundance of room, the spac-may be made 33 in. Anything over 33 in is a waste of room. A space of in in the length of the pew is considered a SITTING.‡

Opera or Theater-Chairs are made 19, 20, 21 and 22 in wide, center to center arms, and in arranging them in rows where the aisles converge, the ends are ught to a line on the aisles by using a few chairs that are either narrower or ler than the standard width. For churches, a standard width of 20 in is least that is desirable. For theaters, 21 or 22-in chairs are commonly used the parquet, 20 or 21-in in the dress-circle, and 20 and 19-in in balcony and lery, although there is no accepted rule in this respect. On account of the t-lifting, opera or theater-chairs may be comfortably spaced 31 in, back to k, and this is the usual spacing in halls and churches. In theaters the irs are usually set on steps. In the upper gallery these steps should not be re than 30 in wide; in the balcony they are usually made either 30 or 31 in

‡ For dimensions of pew-bodies see page 48 of Churches and Chapels, by F. E. Kidder.

wide, and in the parquet, 31 or 32 in wide. As a rule the higher-priced seats are more commodious than the lower-priced.

Estimating Seating Capacity. The actual seating capacity of theaters and audience-rooms can be determined only by drawing the seats to an accurate scale, on the floor-plan, and then counting the number of chairs, or measuring the linear feet of pews.

Approximate Seating Capacity. For approximate purposes the seating capacity or required size of room may be determined by allowing from 7 to 8 sq ft to each seat, or sitting, when on a curve, and from 6 to 7 sq ft to each sitting when in straight rows, the smaller number being used only for large rooms. This allows for aisles and pulpit-platform. For small concert-halls and narrow rectangular rooms, 6 sq ft per sitting will usually be sufficient allowance, provided only that the actual floor-space utilized for seats and aisles is considered.

Seating Capacity of Several of the Older Cathedrals, Churches, Theaters and Opera-Houses *

tes on Theater-Dimensions.†† "The utmost distance from the front of age to the rear ought not to exceed 75 ft, or the limit the voice is capable panding in a lateral direction."

easured from the curtain-line, the San Carlo Theater in Naples is 73 ft; the

From the curtain or back line of proscenium opening.
Measured from stage to center of ceiling.
To the "gridiron" or rigging-loft.
As remodeled in 1893.
Can be enlarged to 40 by 40 ft.
The plan of this theater is in the shape of a horseshoe.
See footnote with table of Seating Capacities of Churches, Theaters, etc., page 1654, ard to data relating to recently constructed buildings of these types.
From The Planning and Construction of American Theaters, by Wm. H. Birkmire.

theater at Bologna, 74 ft. Of the London theaters, the Adelphi is 74 ft, Co
Garden 80 ft, the Gaiety 53 ft 6 in, Lancaster 58 ft 4 in, Marylebone 74 ft
the Globe 47 ft 6 in."

The width of the ideal theater, between inside walls, should be from
75 ft, and "the ceiling should be from 55 to 65, or even 70 ft above the
level."

"The depth of the parquet-floor at the orchestra-rail is governed by t
stage-level, and is generally from 3 ft 6 in to 4 ft 3 in below the stage. A d
of 3 ft 9 in is a good height, as it fixes the eye of the spectator 5 in above
stage-level."

"The height of the stage, that is, from the floor to the bottom of the 'gridi
or rigging-loft, should be 2 or 3 ft over twice the height of proscenium-openi
in order that the fire-curtain may be raised the full height of the openi
There should be a height of 7 ft above the gridiron to enable the fly-men to
their ropes with facility.

Proportioning Gutters and Conductors to the Roof-Surface. The
of gutters and down-spouts and their distance apart for roofs of mill-buildi
with a ¼ pitch and of different spans are shown in the following table: *

One-half roof-span, in feet.......	10	20	30	40	50	60	70	[illegible]
Size of gutter, in inches..........	5	5	6	6	7	7	8	[illegible]
Size of down-spouts, in inches...	3	3	4	4	5	5	6	[illegible]
Spacing of down-spouts, in feet..	50	50	50	50	40	40	50	[illegible]

The specifications of the American Bridge Company provide as follows
the size of gutters and conductors: †

Span of roof	Gutters	Conductors
Up to 50 ft	6 in	4 in every 40 ft
From 50 to 70 ft	7 in	5 in every 40 ft
From 70 to 100 ft	8 in	5 in every 40 ft

Hanging gutters should have a slope of about 1 in in every 16 ft.

"The Produce Exchange Building in New York City, with a roof-area
three-fourths of an acre, roughly speaking, has twelve leaders, each about
in diameter. The roof, which is paved with fire-brick, is graded with slopes
perhaps one in fifty toward the points at which the leader-openings are pl
most of these draining-surfaces being about 40 by 70 ft each. The provi
here made is equivalent to about 1 sq in of leader-opening to 140 sq ft of
surface. On the Sloane Building, at 19th Street and Broadway, New Y
City, with a roof-area of 18 000 or 20 000 sq ft, sloping one in twenty-five, th
are two leaders, each about 6 in in diameter, and a third rectangular lea
4 by 6 in in cross-section. This gives an allowance of 240 sq ft of surface to
square inch of leader-opening, while on the Massachusetts Hospital Life In
ance Company's Building and the Hemenway Building, in Boston, the proport
is only from 60 to 70 sq ft to the square inch of opening." ‡

ELEVATOR-SERVICE IN BUILDINGS*

General Considerations. An efficient elevator-service may be obtained by achines of any one of several types, the choice of the one decided upon for any ilding depending upon varying conditions. The following is a general classi-ation of elevators (see, also, page 1668):

1. Hydraulic elevators:
   (1) Vertical, geared hydraulic type.
   (2) Horizontal, geared hydraulic type.
   (3) Direct-lift plunger-type.
   (4) Inverted (high pressure) plunger-type.
2. Electric elevators:
   (1) Drum-type.
   (2) Worm-gear traction-type.
   (3) Helical-gear type.
   (4) Gearless, traction-type.
      (*a*) Direct-drive (one-to-one) type.
      (*b*) Two-to-one type.

In addition to these, there are also the BELT-DRIVEN type of elevators, and the ND-POWER elevators. The belt-driven type may be either SINGLE-BELT or UBLE-BELT driven, the former being used with a reversible motor and the ter where driving-power is taken from a line-shaft. In view of varying and metimes conflicting claims of competing manufacturers, the architect's de-ion must be governed by impartial engineering judgment rendered after a reful study of the problem in each case.

Geared Versus Gearless Types of Elevators. (See, also, page 1669.) ere has been much discussion regarding the merits and demerits of geared d gearless machines for elevators and the efficiency and future of each. anufacturers of gearless traction-machines have claimed that the use of the lical gear, for example, for elevator-machines, being a relatively recent devel-ment, has not extended over a sufficient length of time to permit of extensive definite data; that they are used for different and less severe service than at for which the gearless traction-machines are employed; and that they can-t rival the gearless traction-machines from the standpoint of efficiency. On e other hand, the manufacturers of helical-gear elevator-machines claim that ars have been in successful use for many years, the substitution of helical ars for worm-gears being the only difference made in the application to their pe of elevators; that the helical-gear elevators installed in some of the highest ice-buildings are doing as much work as any gearless traction-machines; and at the mechanical efficiency of the helical-gear machines is only a little below at of the gearless traction, the electrical efficiency under local or ordinary nning conditions, greater, and the car-mile consumption in kilowatt-hours, less.

Questions of Cost and Efficiency of Elevators. The principal demerit elevator-machines of the gearless type is their relatively high first cost, al-ough even that is much lower than the initial cost of elevators of the plunger-pe. The use of any gear, whether of the helical, worm or spur-type, is, in the inion of many engineers, to be recommended only for the purpose of obtaining

* The matter relating to elevators and elevator-service is condensed and adapted by rmission, from data furnished by various engineers and manufacturers, and papers the Otis Elevator Company, New York City; The H. J. Reedy Company, Cincinnati, io; R. P. Bolton of The R. P. Bolton Company, Consulting Engineers, New York, d author of "Elevator Service"; C. E. Knox, Consulting Engineer, New York; M. W. rlich, Consulting Engineer, New York; and others.

a higher-speed motor, because a higher-speed motor costs less than a low-sp motor. The helical gear is generally considered a more efficient type of g than the worm-gear and has a deserved place in the development of the ele tor-industry. The helical-geared traction-elevators will undoubtedly be tensively used, for the reason that, even if they are not considered by s engineers to be as good in some details as machines of the gearless, tra type, they are less expensive. It is undoubtedly true, however, that the in duction of any gear means some loss in power, and it is claimed that tests that low-speed motors can be designed which are in every way as efficie high-speed motors. The data and statements in the following paragraphs re ing to elevator-service in buildings are presented as useful aids to architects include some opinions and conclusions which are to be accepted or modifie the light of constant additions to engineering knowledge.

A. General Conditions Affecting the Requirements of Specificatio for Elevator-Service *

Electric Versus Hydraulic Elevators. The question of the type of ele tors, whether electric or hydraulic, is best determined by the local conditions the special conditions which exist in every plant. The relation of the eleva equipment to the entire mechanical equipment should be carefully conside and should be decided only after mature deliberation and consultation w unprejudiced engineers and elevator-manufacturers. At the present time about 90% of the elevators being installed are electric, and this includes types of buildings from the small one with but one elevator to the tall s scrapers of the big cities. The electric equipment recommends itself, for it has all of the safety-features of the hydraulic equipment, it is a more fle system, is more adaptable to all kinds of conditions, and requires much less sp The question of space is a particularly important consideration in office-build Furthermore, the control-system is more automatic, the acceleration and reta tion of the car can be made more rapid, and the stops more accurate; the e ciency, also, is higher and in most cases the cost of operation lower. (See paragraph on Comparison of Merits of Electric, Traction and Hydraulic, Plu Elevators, page 1670.)

Location of Hoistways and Machinery-Room. The location of the hoi ways is rather a matter for the good judgment of the architect. In the la equipment all elevators serving one portion of the building and for the s character of service, should be placed in one BANK and not distributed or s rated. Thus, all express-elevators should be together and in one bank, as sho also, the locals. The hoistways should be so placed that the entrances, in stories, are on the same side of the car. In some of the larger cities, two e trances for a passenger-car are not permitted, unless the doors can be contr by the attendant without leaving the operating-device. The machinery-ro should be well ventilated, light and clean as possible, in order that the machin may be given proper attention. This room should also be large enough to m the machines readily accessible for repairs and inspection. Where the mach have heavy parts, which it may be necessary to remove from time to time repairs, it is advisable to locate a trolley-beam with hand-hoist above them facilitate the handling of these parts.

* The Otis Elevator Company, New York, has been of assistance in furnishing m of the engineering data of Section A, of this article on elevators. Among other it considers especially those conditions which should be considered and made de by the architect preliminary to the preparation of the elevator-specifications. paragraphs of Section A should be read in connection with those of Section B, page and the data compared.

lumber and Sizes of Elevators. (See, also, pages 1673 and 1675.) The
lber and sizes of elevators are governed by the following considerations: (1) character of the building, (2) the height of the building, (3) the rentable , (4) the time-intervals between the departures of cars, (5) the number of ies to be served, (6) the average number and length of stops per trip, (7) speed of the elevators and (8) the type of elevators used. No iron-clad s can be given for all types of buildings, but the larger office-buildings, buildings or light-manufacturing buildings have been sufficiently regular esign to warrant some general rules, based upon experience; even in these s, however, the governing conditions vary with the size of the building. of the most essential requirements for a satisfactory plant is QUICK SER- : and in first-class office-buildings the intervals between cars should not ed 30 seconds. The number of stories to be served by a car should be a ideration. For example, in a fifteen-story building, assuming that stops are e at 80% of the stories for one passenger each, and allowing 2 sq ft for each enger, and 4 sq ft for the operator, the car should have an inside area of it 28 sq ft. In order to facilitate unloading and thus increase the efficiency ie system, it is desirable to have the width of the car greater than the depth. he above case, a car with outside dimensions of about 6 ft wide by 5 ft deep ld give the best results, showing a difference of from 15 to 20% between the h and width. In specifying the equipment, it is better to call for several erate-sized cars and a high speed, than for a few large cars of slower speed larger capacities. Thus, three cars, each carrying one-third of all the passen- are better than two cars, each carrying one-half, as the service is increased naking the period between cars less. As the elevator-service largely deter- s the success of a building, it is of vital importance that a sufficient number evators be installed to handle the regular traffic, as well as emergency-con- ns in case of a shut-down. To illustrate what is considered the proper ortion of passenger-elevators for buildings of various heights, the following : is given, based upon a rentable area of 8 000 sq ft per story and 125 sq ft person. This table shows the various combinations for elevators with a d of from 400 to 500 ft and of 600 ft per min for buildings of from 10 to tories above the ground.

Table Showing Number of Elevators Required

mber tories	Express 600 ft per min	Local 600 ft per min	Express 600 ft per min	Local 500 ft per min	Express 500 ft per min	Local 400 ft per min
10	....	4	....	5	....	5
12	....	5	....	5	....	6
15	....	6	....	7	....	7
18	....	7	....	8	....	8
18	Express to 11 5	1 to 11 5	Express to 10 5	1 to 10 5	Express to 11 5	500 ft per min 1 to 11 5
20	....	All locals 8	....	....	....	....
20	Express to 12 5	1 to 12 5	Express to 11 5	1 to 11 5	Express to 12 6	1 to 12 6
25	Express to 15 6	1 to 15 6	Express to 14 6	1 to 14 6	Express to 15 7	1 to 15 7
[illegible]	Express to 18	1 to 18	Express to 17	1 to 17	Express to 18	1 to 18

Buildings equipped with both local and express-service should have the number of elevators for each class of service. In the case of the twenty story building for 600 ft-per-min speed, it is to be noted that the local elev are shown serving from the first to fifteenth story, whereas the express-elev serve from the fifteenth to the twenty-fifth story. The express-elevators not serve as many stories as the locals on account of the extra time consumed the run to the first express-landing. With the distribution as shown, the s for all stories is about equal, and both express-elevators and local elev operate on about the same schedule. In the fourth and fifth columns shown what is considered the best arrangement with the express-elev operating at a 600 and the locals at a 500 ft-per-min speed. Upon compari with the second and third columns, it will be noted that the express-elev are to serve one additional story. This is due to the difference in speed betw the express-elevators and local elevators and is done so that the schedule still remain the same for both. (See, also, paragraph on the Local and Exp Round-Trip Time, page 1675.)

Loads and Speeds. The sizes of the machines or hoisting-apparatus determined by the loads and speeds. The loads for passenger-cars should figured on a basis of 75 lb per sq ft of inside area of platform. The speed very important factor, as the foregoing indicates. This is usually limited local ordinances, and in New York City, cars stopping at all stories are not mitted to exceed a speed of 500 ft per min. For express-service, in that port of the shaft where no stop is made, a speed of 700 ft per min is allowed. Th NO-STOP DISTANCE must be at least 80 ft or more. The best companies for vator-insurance will not permit electric-drum elevators for a speed much o 400 ft per min, whereas the gearless, traction-drive type and the hydraulic typ are approved up to the limits, as noted above. In hydraulic plants it is necess to specify the number of round trips per hour for the entire elevator-equipment This is required in order to determine an adequate pumping-plant.

Hoistways. The hoistways should be finished to plumb-line dimensions that the car running on guide-rails set to plumb-line will at all points have same clearance. Supports should be provided adjacent to the hoistway for overhead beams at a distance, if possible, of at least 4 ft from the top of frame when the platform is flush with the top landing. This distance sho be increased where possible so that the car will have ample clearance, th preventing accidents due to striking the overhead work, in case it should past the top landing. The minimum clearances between the top of the c frame and the overhead apparatus are usually limited by the local building regu lations, and these should be consulted. In the case of the elevators operati at a speed greater than 350 ft per min, the distance given above would probab have to be increased in order to comply with these regulations. A pit should provided at the bottom of the shaft. This should be at least 3 ft deep, and is the case with the overhead clearances, the depth is usually regulated by t building regulations, in accordance with the speed of the elevator. Where possible, the hoistways should be so planned that the main guide-rails may b placed at the sides of the car. Supports should be provided at all the floors these rails, and where the distance between floors is greater than 12 ft, inte mediate supports should be provided. The distance from the supports for th overhead beams, to the penthouse or skylight-roof, varies with the type of in stallation, but can be accurately obtained from the elevator-manufacturer.

Protection of Counterweights. In New York City the Bureau of Buildi requires that where the counterweights run in the same shaft as the car, th must be protected with a substantial screen of iron from the top of the rail t

it 15 ft below, except where the plunger-type or traction-type elevator is l.

uilding Laws Governing Elevator-Installation. The Bureau of Build-, Borough of Manhattan, New York City, issued regulations * governing construction, inspection and operation of all types of elevators, and the ial attention of all architects is called to them, as they are not only obligatory e, but are excellent guides to practice at all times. The foregoing paragraphs intended to give an idea of what the architect must consider and provide building for the reception of the elevator-apparatus, and what he must rmine in order to enable the manufacturer to intelligently design and lay his machinery.

tandard Designs and Special Apparatus. The specifying of apparatus pecial construction is, as a rule, not to be recommended. Standard designs ıld be used as much as possible, as (1) they are more apt to be well designed, ed and built, (2) they are undoubtedly less expensive, both in initial cost maintenance and (3) repair-parts may be more easily and quickly obtained at less cost.

pecifications for Elevator-Installation. The specifications should include ı included in the following classification.

(1) Kinds of service and number of elevators of each service.
(2) Maximum load wanted.
(3) Maximum speed.
(4) Load with maximum speed.
(5) Maximum number of round trips per hour for each elevator.
(6) Method of control. For electric elevators, car-switch control should be used for passenger-service and for all elevators for a speed over 150 ft per min.
(7) Size of hoistways and area of car-platforms.
(8) Travel of car-platform in feet, number of car-landings, and number of openings at each landing.
(9) System used. If electric, direct or alternating current, the voltage and, also, the phase of cycles for alternating current should be given. If hydraulic, the steam-pressure or electric current characteristics for the pump-motors or the water-pressure, if the purchaser provides the pumps, tanks or other source of water-pressure supply.
o) A sketch-elevation showing landings, supports for overhead beams, space for the overhead sheaves, and runbys at top and bottom; a sketch-plan showing size and shape of hoistways, entrances, position of car and counterweight, guide-rails, and location of space available for machines, pumps, tanks, etc., with reference to hoistways.
1) Car and counterweight guide-rails, whether of wood or steel.
2) Supports for fastening the rails, character of these supports, and where and how located.
3) Value of finished car or cage, that is, the specified amount to be allowed for each, the design being subject to the approval of the architect.
4) Number and size of ropes, if not left to the judgment of the elevator-contractor. The largest sheaves possible should always be required, as this factor determines largely the life of the ropes.
5) System of signals, that is, (*a*) annunciators in the cars with push-buttons at the landings, (*b*) UP and DOWN signals in the cars, with UP and DOWN buttons at the landings, so arranged that a car going up receives only

* Published in the Record and Guide, July 29th, 1911.

UP signals, and a car going down receives only DOWN signals, the signal being automatically reset by the first car stopping at the floor from which the signal is given. This system adds greatly to the efficiency of a battery of elevators, as it avoids the confusion of more than one car answering a signal, or a car going in one direction stopping for a passenger going in the opposite direction. The number of stories at which each car is to land should always be specified.

(16) Indicators. Whether at the ground-floor only, for the information of the starter regarding the position of the cars, or at all floors. Indicators are unnecessary with the automatic signals last described, except at the ground-floor, as there is at each floor an UP and DOWN signal to show the first available car in either direction.

(17) Source of power. It should be specified whether the connections will be brought to the elevator-apparatus by the purchaser or by the elevator-contractor. If by the latter, a sketch should be made showing the distance, and for the electric system the specifications should state whether the wiring is to be open, that is, on cleats, in moldings, or in conduits; the sizes of wire, and the switches, cut-outs, etc. For the hydraulic system, the size of pipe for steam-supply should be given. The sizes of water-piping should be left to the elevator-contractor and he should be held responsible for them. Also, in the case of an hydraulic system operating from street-mains, the specifications should state by whom the piping is to be done and who is to furnish the water-meter.

(18) Pumps and tanks in hydraulic plants. These should be furnished by the contractor. The specifications should state whether the capacity is to be just ample to do the work, or whether there is to be a reserve capacity, with reserve-units, to provide against interference with the service in case of accident to a pump or tank, or for future elevators, but the sizes and design should be left to the judgment of a responsible elevator-contractor.

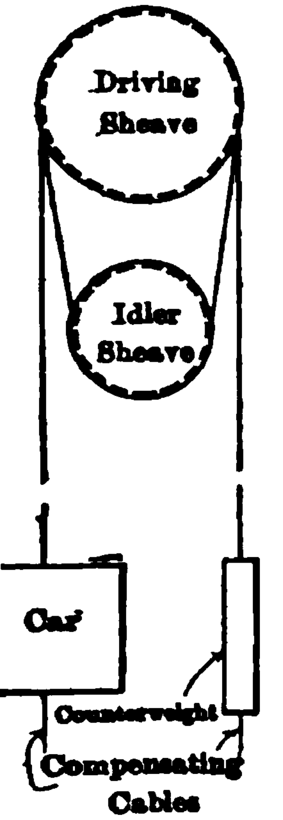
(19) Foundations for the machine, whether they are to be provided by the purchaser or by the contractor.

(20) Miscellaneous. Gratings underneath the overhead work, pitpans, painting in addition to the standard factory-finish and all items not mentioned above are generally furnished by the purchaser under separate contracts, but this should be clearly set forth in the elevator-specifications.

Safety-Devices for Elevators. (See, also, page 1672.) The question of safety-devices cannot be too carefully considered for all elevators, and for passenger-elevators in particular only the best and most thoroughly tested apparatus should be installed. Each car should be equipped with the mechanical device designed to grip the rails and stop the car in case it exceeds a predetermined maximum descending-speed, either from breaking of the cable or from any other causes. This safety-device should be mounted upon the car-frame beneath the platform, and should be operated by means of a speed-governor located overhead. For speeds above 150 ft per min, this gripping of the rails should be done gradually. In New York City the instantaneous stopping is not allowed above a speed of 100 ft per min. A switch for emergency use should be placed in the car of electric elevators. The opening of this switch should stop the car immediately and independently of the regular operating-device. All electric elevator-machines should be equipped with an electric brake. This brake should be automatically applied when the car stops or which

current-supply is interrupted. The brake should be released electrically and lied by means of spring-pressure. Automatic limits should be placed at top and bottom of the hoistway, to automatically slow down and stop the at the limits of travel, independently of the operator.

earless Traction-Elevators.* Among the more recent developments of elevator industry is the electric, gearless, traction-elevator (Figs. 1 and 2). e, also, Fig. 5.) The designing of an efficient slow-ed motor made it practical to build a traction-machine h the driving-sheave mounted directly upon the armature-shaft, thus eliminating the use of gears to reduce to the desired car-speed. This gearless machine is used for speeds from 250 ft per min and above. The manufacturers of this type of machine claim that it is the outcome of a general tendency toward simplicity in design with efficiency in operation. The machines are generally located over the hatchway. The car is supported by cables which lead from the car directly over the driving-sheave, with overhead installation, then partially around the auxiliary idler or leading-sheave and again over the driving-sheave to the counterweight. With this arrangement a complete turn around the driving-sheave and the idler-sheave is obtained, giving sufficient tractive effort to drive the car. The machine being placed overhead, the cables can lead directly to the car and counterweights; and as this allows the cables bend in the same direction, it is claimed by the manufacturers that s an advantage and that the life of the cables is appreciably lengthened. cial hitches are used for connections to the car and counterweight to nteract the twisting effort due to the reaving of the cables. As soon either the car or counterweight is obstructed, the tension in the cables is reased and consequently the tractive effort reduced. This arrangement, s claimed, brings either the car or counterweight to rest and prevents ning by the limits of travel, and into the overhead beams, should either mber land on the buffers at the bottom of the shaft. Underneath both car l counterweight are placed oil-buffers designed to bring the car or counter-ght to rest at the limits of travel, from full speed. At the top and bottom he hatchway the car is stopped automatically by a series of electric switches. e operation of these switches is so timed that the car is brought to a smooth l gradual stop. The slow-speed shunt-motor, with its control, makes a flex-system. The acceleration and retardation may be arranged to suit the ticular service-requirements. For speeds below 450 ft per min, it is the prac-to obtain the slow speed by passing the cables around sheaves mounted in



. 1. Roping for to 1 Traction-achine

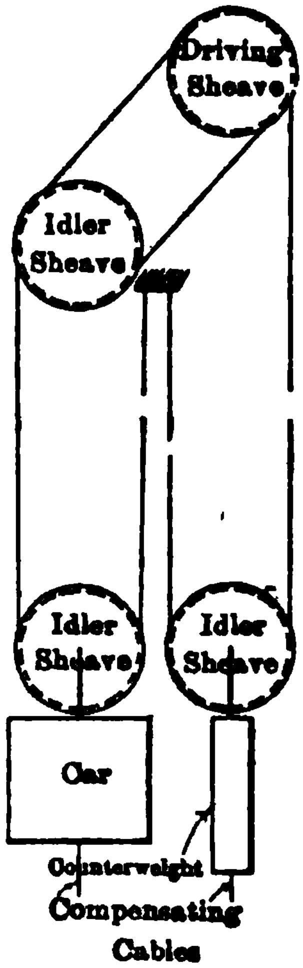


Fig. 2. Roping for 2 to 1 Traction-machine

For full and valuable data relating to the relative advantages of the helical-gear ators as compared with those of the traction-type, see papers published by the H. J. dy Company, Cincinnati, Ohio, and others advocating the geared machines. Editor.

the cross-head of the car and of the counterweight, and anchoring the cab the cables at the top of the hoistway. These sheaves, with their ball bearing are specially made to withstand the heavy service to which they are subject In addition to the above details, elevators of this type should be provided wi all of the regular safety-devices used with passenger-elevators.

Electric Elevators with Push-Button Control. One of the most ingeni and serviceable developments in the elevator-industry is that of the automa electric elevator with push-button control. In New York City this type elevator is permitted only in residences, but in other cities it is used in apart ments, hospitals, and other places where the service is very light and intermitten and it is desired to dispense with an attendant. In the design of these elevat it has been the aim to provide all safety-devices and appliances to make the i stallation absolutely safe, so that the elevators may be operated even by a chi alone, without danger. In each story is located a button, similar in appeara to the ordinary signal-button, and the passenger, by pressing this, may call t car, if it is unoccupied or not in use, to any story. The car comes to the st at which it is required, and stops automatically. When it comes to rest in th story, the entrance-door to the hoistway is automatically unlocked, and it then possible for the passenger to open the door and the car-gate, and enter t

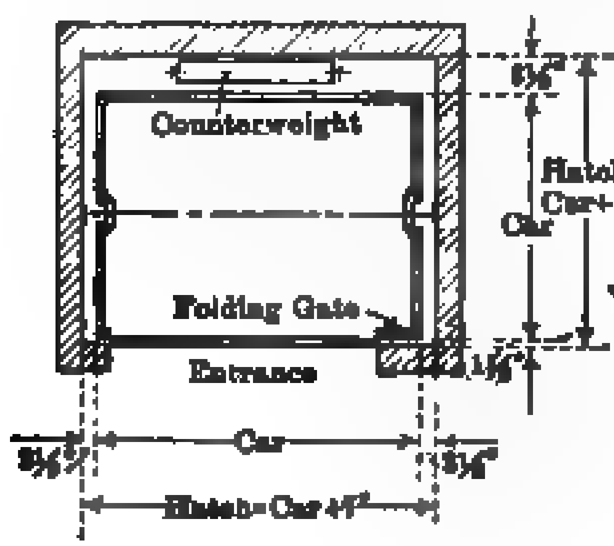

Fig. 3. Standard Hatchway and Car-platform. Side-guides

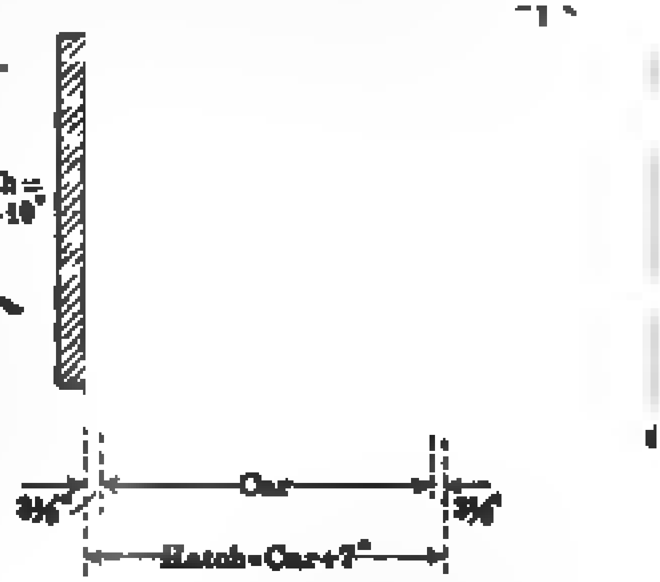

Fig. 4. Standard Hatchway and Car-platform. Corner-guides

car. The hoistway-gates and the car-gate are so arranged that the machine inoperative until both are tightly closed. The hoistway-doors can be open from a hall, only when the car is at the landing of that particular hall. In t car is a bank of buttons corresponding to the various stories served, and al a stop-button or emergency-button. After entering the car, and closing t hatchway-door and the car-gate, the passenger can push the button in th car corresponding to the story to which he desires to go. The car will proce to the designated story and stop automatically. Should the passenger desi for any reason, to stop the car at any point of its travel, he can do so by pushi the stop or emergency-button. The car is in the complete control of the pa senger, as, after the initial operation of calling or sending it to a landing, further operation cannot be interfered with until after both the hatchway-d and the car-gate are opened and closed. This means that no other perso call the car until after the passenger has reached the desired landing, left car, and closed the gate and door. In some equipments for elevators of this ty the device for releasing the door-lock is prevented from operating while the is in motion. This is a very desirable safety-feature, as otherwise each

mporarily released as the car passes up or down the hoistway, and a person i landing can open the door during the momentary period that it is unlocked. ome cases the gate on the car is omitted; but this is a very dangerous prac- and should not be permitted. Elevators of this type are designed for oper- ı with direct current or alternating current, and single or multiphase ıits. Single phase should be avoided, if possible, and before deciding upon type of current, the consent of the electric power company should be ob- ɜd for placing upon their lines a motor with the heavy inrush of current ired at starting.

tandard Relations of Hatchway, Platform and Car-Sizes. (See, also, : 1675.) In Figs. 3 and 4 are shown some typical elevator-layouts for ric installations, with side and corner-posts and steel construction. (See, Fig. 7.) The clearances shown are for elevators traveling at a speed of ft per min or more, and may be reduced about 1½ in for elevators of slower d. Some of the minimum dimensions given with Figs. 3 and 4 vary slightly . those given with Fig. 7 and in Table D, page 1676, but agree in the essen- requirements.

B. Electric, Passenger-Elevator Systems *

levator-Development. The object in view in presenting this material is :o discuss all the details of elevator-construction or the mechanical features, to outline the results of a study in connection with the economic division of enger-elevators and an efficient elevator-service for the traffic of the modern nercial or distinct type of office-building. The requirement of such build- is a very ample and adequate elevator-service, not only because the mon- value of the building may otherwise be affected, but in time of necessity, ıring a fire or other panic, the occupants must be readily brought to safety. ng the early development of the sky-scraper the necessity for a proper ıtor-service was partly overlooked, and perhaps not altogether realized, for : of the older buildings suffer from a lack of traveling-facilities, resulting ı inconvenience to the many occupants. The tenants of the upper stories herefore obliged to wait on the up trip of the elevator, and the people occu- ; the lower portion of the building are left behind on the down trip.

ıe Extensive Use of Elevators. To fully indicate the extensive use to ı the elevator has been adopted for passenger traffic in large cities, the in- e of the Borough of Manhattan of New York City is given. There were 14 about 10 000 machines in service, twice the number that were in oper- in 1904, and these were divided among the different classes of buildings ximately as follows:

5 000 elevators in office-buildings over 10 stories high.
1 500 elevators in office-buildings under 10 stories high.
500 elevators in loft-buildings.
700 elevators in residences.
800 elevators in apartment-houses.
500 elevators in department and other stores.
1 000 elevators in hotels, clubs, institutions, etc.

he matter in Section B of this article on Elevators is, by permission, condensed lapted from data contained in papers by M. W. Ehrlich, consulting engineer. The first appeared in the April, May and June, 1914, issues of Electrical Engineering, fterwards were published in condensed form in Lefax, by the Standard Corpora- f Philadelphia. Section B includes a brief outline of elevator-development, some nic considerations and some installation-data, and the paragraphs of this Section be read in connection with those of Section A, page 1580, and the data compared.

Besides these passenger-cars, the buildings requiring freight-service in an additional 10 000 machines.

Two Common Types of Elevators. In modern elevator-practice are but two common types of successful machines in use, the hydraulic and tric elevators. These may both be subdivided in the classification acc

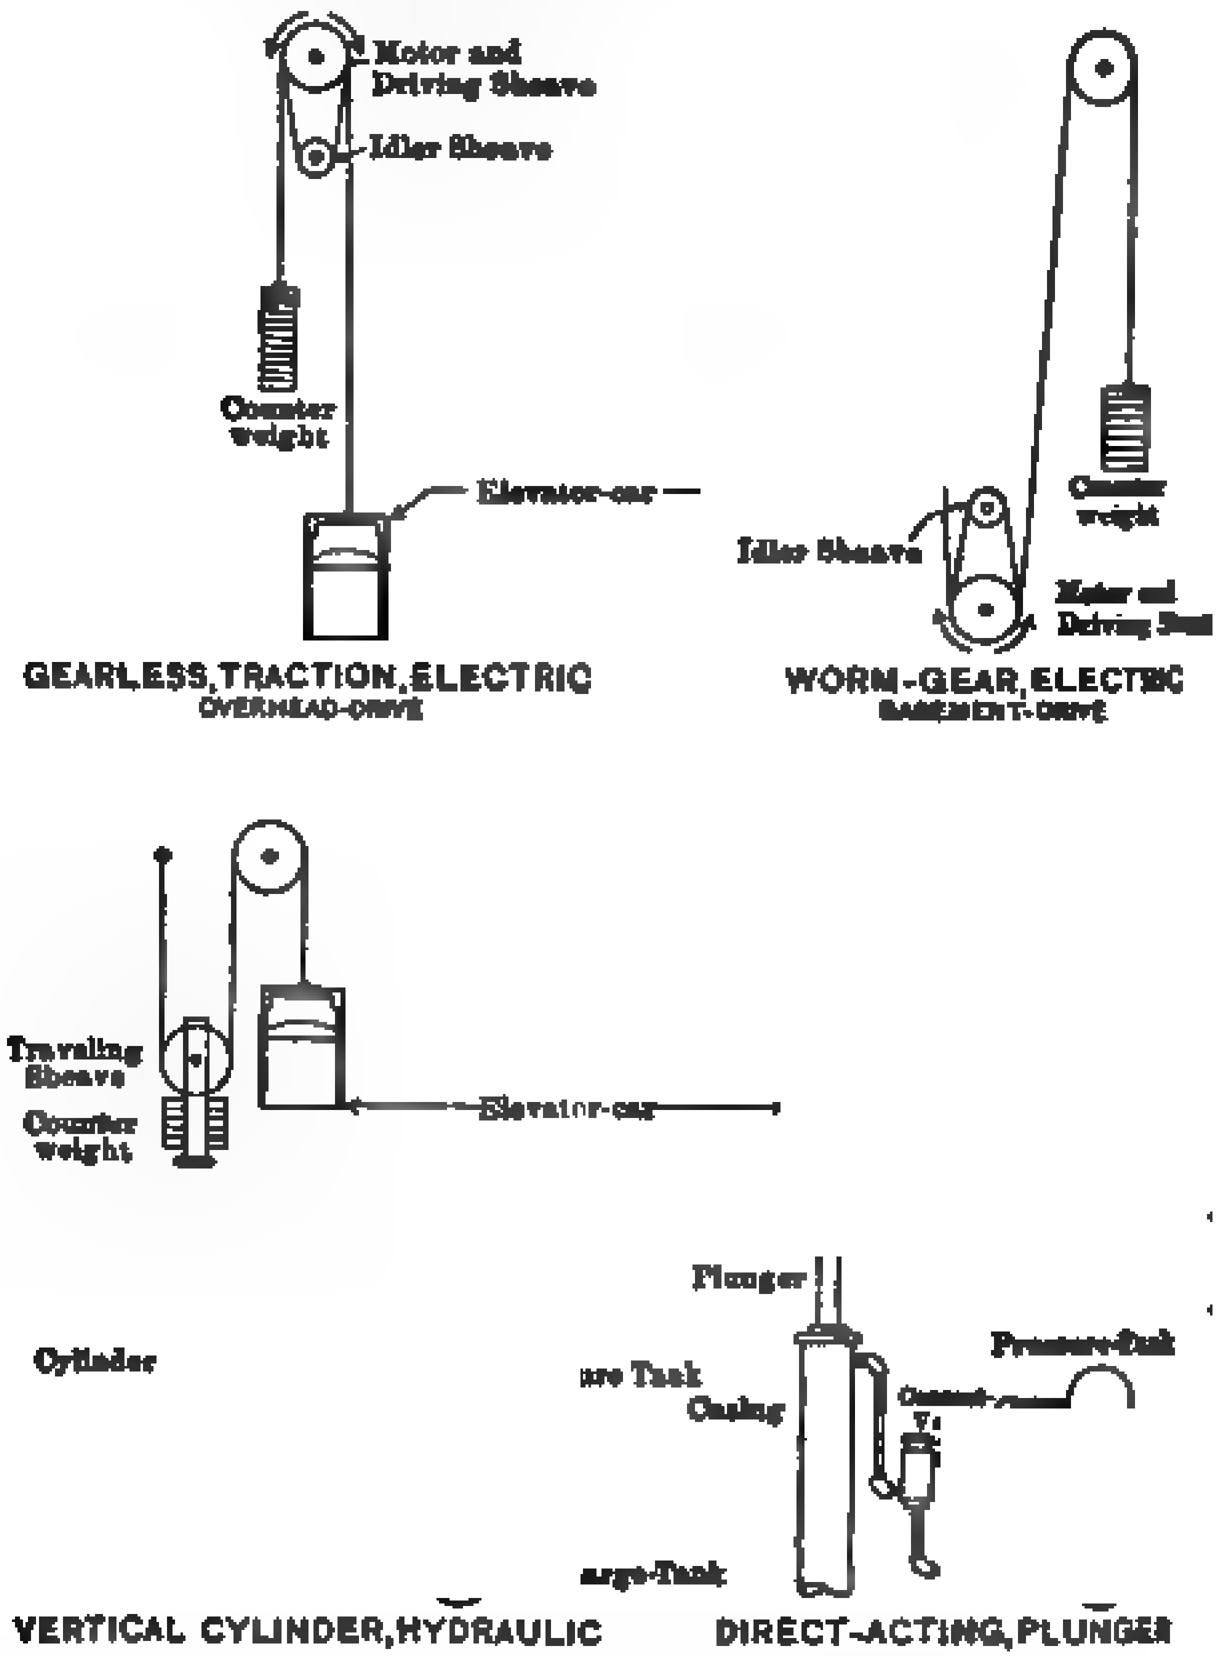

Fig. 5. Some Types and Varieties of Elevators

to the mode of drive or operation and the transmission of power, thereby an apparent variety of elevators. The machine of the hydraulic type of the vertical-cylinder pattern or of the plunger-type, while the electrical ratus may be of the drum, worm-gear or gearless traction-type. Some types and varieties are illustrated in Fig. 5. (See, also, Figs. 1 and 2, and general classification on page 1659.)

A Short Historical Account of the Development of the Com Passenger-Elevator brings one back a little more than half a century

oduction of the first STEAM-ELEVATOR. This form of drive was soon replaced the WATER-BALANCE type of hydraulic elevator, which, even though a faster hine, proved to be, in operation, quite dangerous. For a number of years type enjoyed the distinction of being the only high-speed apparatus until advent of the VERTICAL-CYLINDER HYDRAULIC ELEVATOR, about twenty s later. Running-speeds as high as 400 ft per min were readily attained, on account of the ease in handling and the safety in operation, these ele- rs soon gained favor and were the only types of machines installed in the tall buildings. The electric DRUM-MACHINE made its first appearance in York during the year 1889, and owing to the merits of this new system, electric machine soon established itself as a successful competitor with the raulic type. The only obstacle remaining was to overcome the slower d, and this brought out the Sprague LONG-SCREW ELECTRIC ELEVATOR. ators of this type proved quite costly to maintain and operate, but on unt of their possibilities of speed and high rise, were installed in several structures. These different types of elevators helped considerably in the lopment of the sky-scraper buildings, and as further building projects ght on an extension in height, a hitherto unknown condition of passenger- ator service had to be met. About the year 1900 the DIRECT-ACTING GER HYDRAULIC ELEVATOR was introduced to fulfil this increasing demand ontinued high rise with high speed. The inherent safety in operation and relatively high economy allowed for no doubt as to the possibilities of the GER, but after several years, experience pointed out that the advantages he hydraulic plunger-elevator were somewhat limited in certain directions, only under conditions of a rise not exceeding 150 ft could the character- of the safe and economical plunger-elevator be maintained.

action and Geared Elevators. (See, also, page 1659.) Recent experi- s conducted to perfect an electric elevator that would meet the growing irements of heavy passenger traffic in the newest form of tall office-build- have resulted in the production of what is now commercially known as the TO-ONE, OR GEARLESS TRACTION-ELEVATOR. Among the earliest New York llations of this type of electric elevator may be named those in the Singer ding and Tower, and later those in the Metropolitan Building and Tower, the latest developments include the Woolworth and the Equitable Build- The apparatus used in the Municipal Building is one in which the ines are an adaptation of the usual double-worm-and-gear drive between atively high-speed motor and a cable-drum, a double set of intermeshing gears being employed between the two gear-shafts. In summarizing, it t be well to mention that the commercial or useful life of an elevator and mbined mechanisms seldom exceeds fifteen years, and that where remod- has been resorted to, the ELECTRIC DRUM and WORM-GEAR TRACTION have ly been substituted for the HYDRAULIC TYPE in buildings not exceeding twelve to sixteen stories in height; and that in higher structures the ss traction-elevator or its modification in the form of an electric TWO- E TRACTION-ELEVATOR has been resorted to.

fety of Electric and Hydraulic Elevators. (See page 1664.) It is however, that both the electric and hydraulic types of elevators have perfected to a state of high efficiency, and they may, therefore, be used entire safety. Of the hydraulic types it may be said that the plunger- ors are inherently safer than those which are suspended, or than even the modern electric traction-elevators; but it cannot be denied that the many ments and improved appliances attached to elevators of the various electric have made the latter as reliable as hydraulic machines designed according

to best practice. It is claimed that the electric traction-elevator is [illegible] free from the element of danger because of the improved methods of [illegible] transmission and the peculiar form of windings used for the drive.

Comparison of Merits of Electric, Traction, and Hydraulic Pl[illegible] Elevators. In narrowing down the question as to the merits of the ELE[illegible] TRACTION-ELEVATOR and of the HYDRAULIC PLUNGER-ELEVATOR for pass[illegible] service in tall office-buildings of to-day, it might be well to note that the elevator-installations, almost without exception, have favored the el[illegible] Not only is the cost of installing the traction-machine from 25 to 35% les[illegible] that of the plunger-type, but the room occupied by the driving-machine [illegible] reduced to a minimum, and, as a matter of fact, may be placed at the head [illegible] directly over the elevator-shaft. If no local supply of electricity is availab[illegible] the premises, the public source may be resorted to. The difficulty with [illegible] plunger-elevator for high-rise, high-speed work lies in the requirement for [illegible]ing the mass of water and the massive plunger proper, and as this [illegible] weight cannot be readily and smoothly stopped, the result is a sluggish [illegible] starting and stopping. At any rate, it remains an open question as to wh[illegible] the economic values attached to modern buildings would favor the install[illegible] of the plunger-elevator, with its accompanying pumping-plant, which n[illegible]sarily occupies considerable floor-space. The choice, therefore, would [illegible] favor the HIGH-RISE, HIGH-SPEED ELECTRIC TRACTION-ELEVATOR for pass[illegible] service. (See, also, paragraph on Electric Versus Hydraulic Elevators, [illegible] 1660.)

Table A. Relative Operating-Costs of Elevators

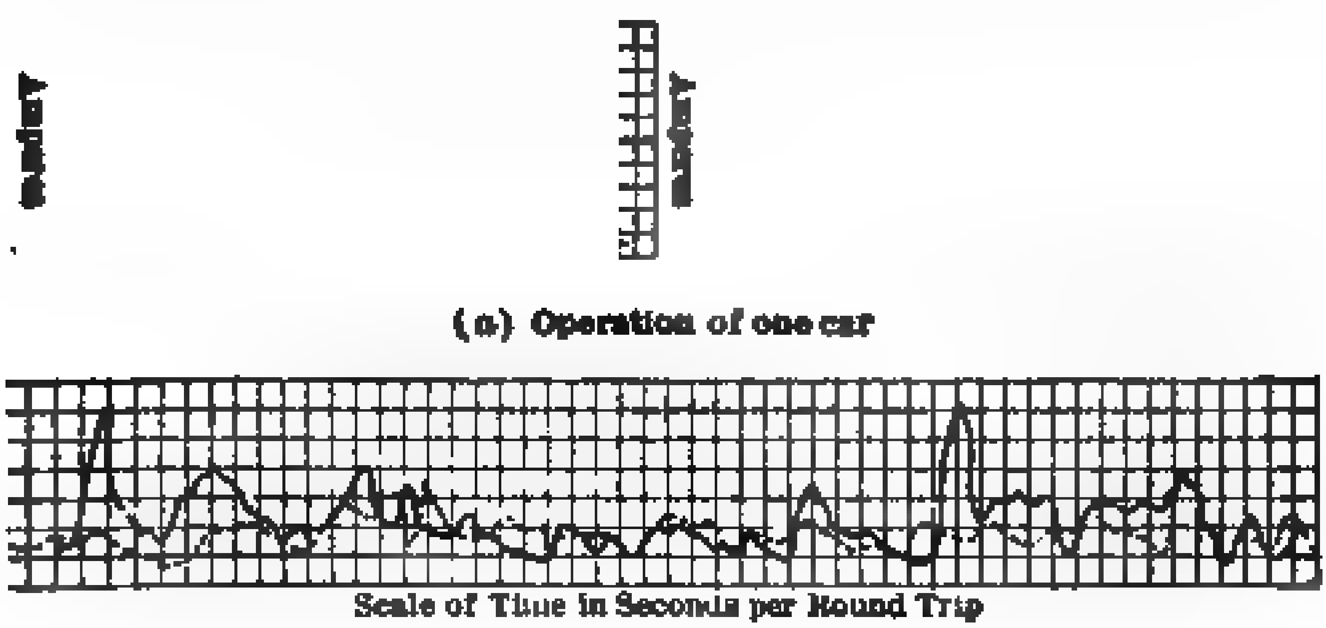
	Office-building				Loft-building				Apartment-[illegible]		
	Traction electric	Worm-gear electric	Vertical-cylinder hydraulic	Direct plunger	Traction	Worm-gear	Hydraulic	Plunger	Traction	Worm-gear	Hydraulic
[illegible]ls	85	72	68	65	80	68	[illegible]		8[illegible]	60	55
Cents per car-mile	25	22	20	19	23	20	1[illegible]			18	17
Dollars per car per annum	2 100	1 890	1 680	1 600	2075	900	[illegible]		60[illegible]	510	[illegible]
Per cent of all operating-costs . ..	14.1	12.0	11.3	11.0	18.0	15.4	1[illegible]		6[illegible]	12.0	11.[illegible]

Relative Operating-Costs of Elevators. The figures given in Tab[illegible] may prove of interest in pointing out the relatively higher operating-costs [illegible] different ELECTRIC types over the VERTICAL-CYLINDER HYDRAULIC and PLU[illegible] ELEVATORS. The values given represent only the cost of labor, power, re[illegible] and supplies. By a close perusal of the amounts listed, it will be con[illegible] that the economies of the plunger cannot be utilized beneficially in tall [illegible] buildings, on account of the mechanical difficulties, and in other types of [illegible] buildings, allowing for a low rise, the installation cost becomes exorbitant[illegible] the relatively high first cost of this type of machine were taken into consid[illegible]tion, with an addition for the extra cost in building-construction necessar[illegible] the space occupied by the pump and tank-equipment, the total expendit[illegible] the whole would show no great favor either way. In explaining the v[illegible] given in Table A, it should be understood that the figures are computed [illegible] basis of actual records of several buildings that have been brought to the [illegible]

e. The general method of comparing records in business buildings is to are the costs with the total annual income or rental. The total oper- -costs include the expense in the mechanical, electrical and building rtments, covering all costs of labor and material for the maintenance of the ent divisions of service. Therefore the annual cost of operating an ele- :-system is given as a percentage of the gross rentals received, and is er stated as a percentage of the total operating-expenditure of the build- under consideration. The average cost in cents per car-mile traversed is given, together with the average annual cost in dollars to pay for the ' of operating and repairing, the necessary power, and the material and lies required per single elevator.

onomic Considerations. The efficient operation of an elevator-system not rest altogether on the economic division and disposition of the cars, as uman element becomes one of the main factors. It is self-evident, there- that the service of an elevator is limited not only by the different classes of ngers entering, riding and leaving the conveyance, but by the experience e hallman or STARTER and his ability to understand the demands of the c and the personal peculiarities of the elevator-operators.

me-Schedules. It is now common practice to dispatch the various ma- s of an elevator-system on a predetermined time-schedule, thus avoiding great extent any confusion or overcrowding that would otherwise arise. s been well established that the travel of elevators under consecutive-trip lule-operation allows for a highly efficient service, not only in the handling e traffic, but in the demand for power, which is thereby reduced to a min- a.



(a) Operation of one car

(b) Operation of a bank of elevators

Fig. 6. Recorded Current-consumption of Gearless Traction-elevators

wer-Diagrams. The POWER-DIAGRAMS (Fig. 6) point to the effect of a and a proper service under different conditions. The upper curve (a) was under test-conditions and represents the operation of one elevator. The in the single car is approximately equal to the designed machine-balance, on the up and down trips, and the number of stops corresponds to the ge per car per mile under actual service in office-buildings. This diagram en mainly to allow for a proper understanding of the combined curve (b), ing the actual round-trip operation of a bank of elevators in one of the New sky-scraper buildings at an early-morning hour. The full or solid-line shows an excessive power-demand due to an inconsistent SCHEDULE, the

cars having been dispatched by a starter who may be identified as X, whi dotted or broken-line curve shows the more expert handling under the conse trips by starter Y, the same operators running the cars in each case.

Safety-Appliances. (See, also, page 1664.) To minimize the many dents in elevator-practice, a SAFETY-LOCK is recommended, so attached will not permit the elevator to leave a landing until the gate has been Accidents are seldom, if ever, due to the faulty behavior of the elevator but sometimes the breaking of suspension-ropes, as recorded by a relatively cases, will result in a serious accident. The most frequent cause of acci connected with the operation of elevators, is that due directly to the gence of the operator in handling the doors or elevator-gates, and this avoided by the installation of the safety-locks above recommended. as has been practically demonstrated, many of the safety-appliances older installations designed to stop a falling elevator have usually failed but the improved wedge-type of JAW-SAFETY, actuated by a SPEED-GOV and attached to the more recent installations, usually acts when the exceeds its normal running-speed. This generally occurs when the design safe-distance limit has been passed, and the jar occasioned by the final of the car is not altogether a pleasant experience. The serious injuries fatalities due to the falling of an elevator are proportionately small when pared with the entire list, and amount to about 20% of the total, whereas loss of life caused by open and unlocked gates in elevator-practice accounts for the remaining 80%. The only safety-device, therefore, that be called useful, as it eliminates the personal element, is a SAFETY-LOCK the several automatic devices now available for this provision of safety, serve merit; and while some are purely mechanical, others are actuated trically, and only by the installation of such automatic locks will unnece elevator-accidents be avoided.

Signal-Systems. A SIGNAL-SYSTEM is essential to an efficient service. matic electric-light indicators at the different landings, with a mecha indicator on the ground-floor or street-landing, will be found highly eff even though not the simplest. Briefly described, the system is composed dynamotor supplying current for the magnets, push-buttons and lamps. each landing one or more sets of push-buttons are arranged for both the UP DOWN signal, and over each elevator-gate two lamps of different color, one another, to indicate the direction of car-travel; and each elevator-car is provided with a signal-lamp and a transfer-switch or push-button. A mech ical indicator on the main landing informs the starter as to the location of different elevators, and thereby aids him in exercising full discretion as to to dispatch the next car. The general system operates in a manner appr mately as follows: When a push-button is pressed for either direction story, it actuates a magnet corresponding to that story, which in turn sig to the operator in any approaching car, thereby indicating a waiting passe and, according to the movement of the elevator, further contact is made the outside signal-lamps at that story showing to the waiting person the approaching that floor. In a properly proportioned elevator-system the tr fer-switch is seldom used, but in buildings in which the travel becomes over during the rush-hours, and when an approaching car is filled to its cap the operator may press the transfer-button and thereby signal the car follo

Traffic-Capacity of Elevators. The TRAFFIC-CAPACITY of an elevat its passenger accommodations must necessarily be of such proportions handle the travel of the tenants of the building and also of their visitors sure a proper working schedule. From a study of existing systems in which

ator-service is considered adequate, it is found that the questions of BUILD--OCCUPANCY as related to BUILDING-AREA and elevator TRAFFIC-CAPACITY be combined into a consideration of a proper UNIT AREA for the elevator. egard to the determination of the MAXIMUM TRAFFIC-CAPACITY of a passenger-ator, experience shows that an average weight of 140 lb may be allowed for passenger, and as each size of car has its corresponding load at the rated d, the total load divided by 140 gives the maximum number of passengers an ator can accommodate at its designed speed. In another simple computa- for this result, an allowance of 2 sq ft of car is made for each passenger. The imum capacity of an elevator may be of interest in computing the time re-ed to empty a building in case of emergency; but when a car of proper unit is installed, this condition is taken care of. Tests have shown that the RAGE PASSENGER TRAFFIC of an elevator-system bears a definite relation to TENANCY of the building, and to the MAXIMUM TRAVEL, the result being that essed in Formula (6).

umber of Elevators. (See, also, page 1661.) Modern practice tends to that the NUMBER OF ELEVATORS required for any office-building is really rned by the physical aspects and conditions of that building. Whereyer it t practicable to use a car of large area, the number required will certainly n excess of that necessary when large cars are used. It is not advisable, efore, to base any conclusions on the number of cars to adequately satisfy rtain condition, unless the UNIT AREA OF THE CAR is considered.

ocal and Express-Elevators. Another important consideration is the ion so common in high-class office-buildings, namely, the proper service of L and EXPRESS-elevators.

ormulas for Elevator-Service. The formulas given below are well sub-tiated, and give economical service-conditions based on existing systems in larger cities of the United States. By these formulas the number of eleva- required, the division of service, and their operation may be determined.

$$E = A/24\,000 \qquad (1)$$

$$f = n/2 + 2 \qquad (2)$$

$$Te = (25/s + 5/100)\,n \text{ and } Tl = (25/s + l/10)\,n \qquad (3)$$

$$Me = 2\,n/7\,Te \text{ and } Ml = 2\,n/7\,Tl \qquad (4)$$

$$Ce = 115\,n/100\,Te \text{ and } Cl = 115\,n/100\,Tl \qquad (5)$$

$$pe = 300/Te \text{ and } pl = 300/Tl \qquad (6)$$

notations in the formulas are:

E = number of elevators required
A = square feet of gross building-area served
f = story at which express-run terminates
n = total number of stories served
s = speed of elevator, in feet per minute
Tl = local round-trip time, in minutes
Te = express round-trip time, in minutes
Ml = miles traveled per hour by local
Me = miles traveled per hour by express
Cl = current consumed per hour by local, in kilowatt-hours
Ce = current consumed per hour by express, in kilowatt-hours
pl = passengers carried per hour by local, one way, up or down
pe = passengers carried per hour by express, one way, up or down

e figures in Table B represent the AVERAGE LOAD AND SPEED-COMBINATIONS rious heights of buildings, together with the usual AREA OF THE ELEVATOR-

CAR consistent with the standard sizes manufactured, and should be [illegible] basis for selecting the proper unit areas in connection with Formula [illegible] many factors entering into the operation of an elevator would affect the c[illegible] consumption to a considerable extent, as may be seen in Fig. 6, previ[illegible] plained. But Formula (5) agrees with modern service under average ope[illegible] conditions.

Table B. Unit Area, Load and Speed-Combinations

Number of stories	Car-area, sq ft	Load, lb	Speed, ft per min
8 to 13	25	1 700	250 to 350
14 to 22	30	2 000	350 to 600
23 to 30	40	3 000	400 to 600

Table C. Elevator-Installation Data

1	2	3	4	5	6	7
Building		Number of elevators required

Installation-Data. In order to facilitate the ready understanding of the rious formulas given, Table C, embodying the computations, is presented. ne various headings included are numbered in respective order from 1 to 12, that an explanation of the items considered will not be confusing. Under lumn 1 is listed the heights of buildings, with the assumed floor-areas, extend- g the full height of the structure, given in column 2. In column 3 are listed e actual square feet of car-area now provided in many buildings of similar or-space and with an adequate service. This is intended as a guide where e considerations in planning the building have included a means of accom- odating the standard-sized elevators most suitable for that building and where rious attention has been given to the disposition of the cars. But, on the ner hand, the values listed may also be used to advantage in proportioning e number of elevators required under any conditions, and where the physi- aspect of the building does not allow for an economic disposition of the vators. Any conservative unit area best suited to the conditions may then allotted for each car, and the number of elevators then determined. Col- ns 4, 5 and 6 give the numbers of cars for various standard unit areas, while e values in column 7 are computed by Formula (1).

The Local and Express Round-Trip Time for different running-speeds given in columns 8, 9, 10 and 11 of Table C, and the value for f as given Formula (2) is given in column 12. It will be noticed that in columns 8 d 9 the time occupied in traversing the heights of buildings exceeding eighteen ries is slightly more than would actually prove economical. It might be well, refore, to point out that the speeds of local elevators for high buildings might increased to advantage; but whether the service is local or express, it is not visable to exceed a speed-rate of 600 ft per min. In order to rectify this con- ion, under the speeds considered, the number of express-elevators must then more than half the total number in the system, and a subdivision of express- vice proper is also necessary. (See, also, Table Showing Number of Eleva- s Required and notes following, page 1661.)

Sizes of Hatchways and Car-Platforms. (See, also, page 1661.) The es of elevator-car platforms and hatchways of unit areas heretofore con-

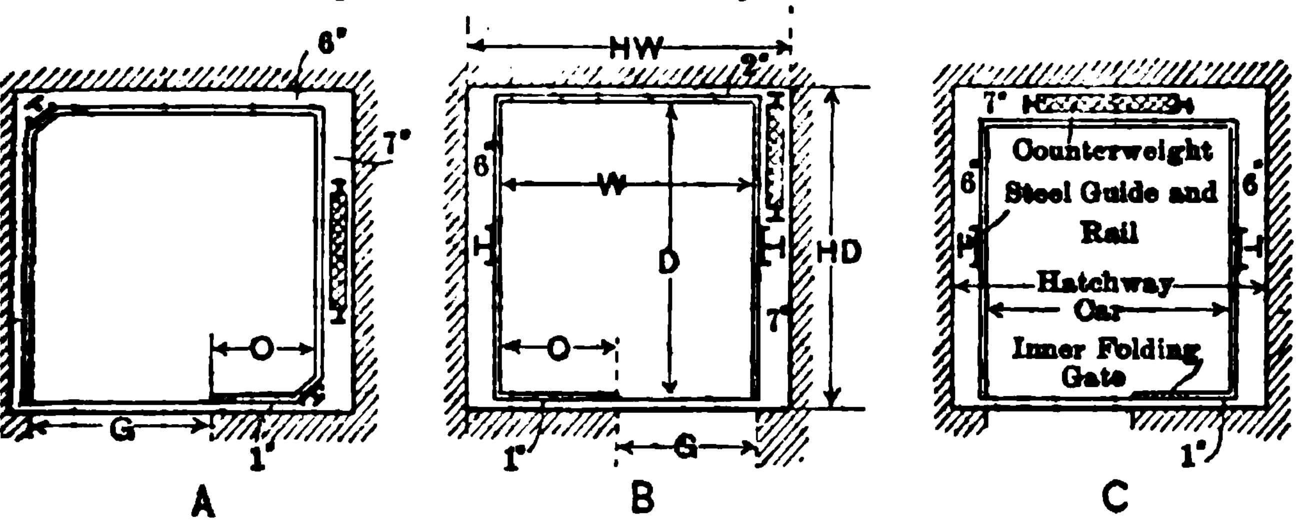

Fig. 7. Typical Layouts for Elevator-hatchways and Car-platforms

red are shown in the following diagrams (Fig. 7) illustrating three typical ns of modern installations with steel guide-rails. (See, also, Figs. 3 and 4.) gate or door-opening may be either right-hand or left-hand, as best suited lanning, structural, or other conditions. The clear inside dimensions of the ssary hatchway are given, and also the clearances required between this and car. Some of the minimum dimensions given with Fig. 7 and in Table D r slightly from those given with Figs. 3 and 4, page 1666, but agree in the ntial requirements.

Table D. Sizes of Elevator-Car Platforms and Hatchways

Dimensions	Area of car-platform					
	25 sq ft		30 sq ft		[illegible] sq ft	
	ft	in	ft	in	ft	in
W = inside width of car	6	0	6	3	7	[illegible]
D = inside depth of car	4	3	4	9	5	[illegible]
O = space for operator	2	3	2	3	2	[illegible]
G = gate-opening	3	9	4	0	4	[illegible]
HW = hatch-width, car A	7	0	7	3	[illegible]	[illegible]

car C	5	2	5	8	6	[illegible]

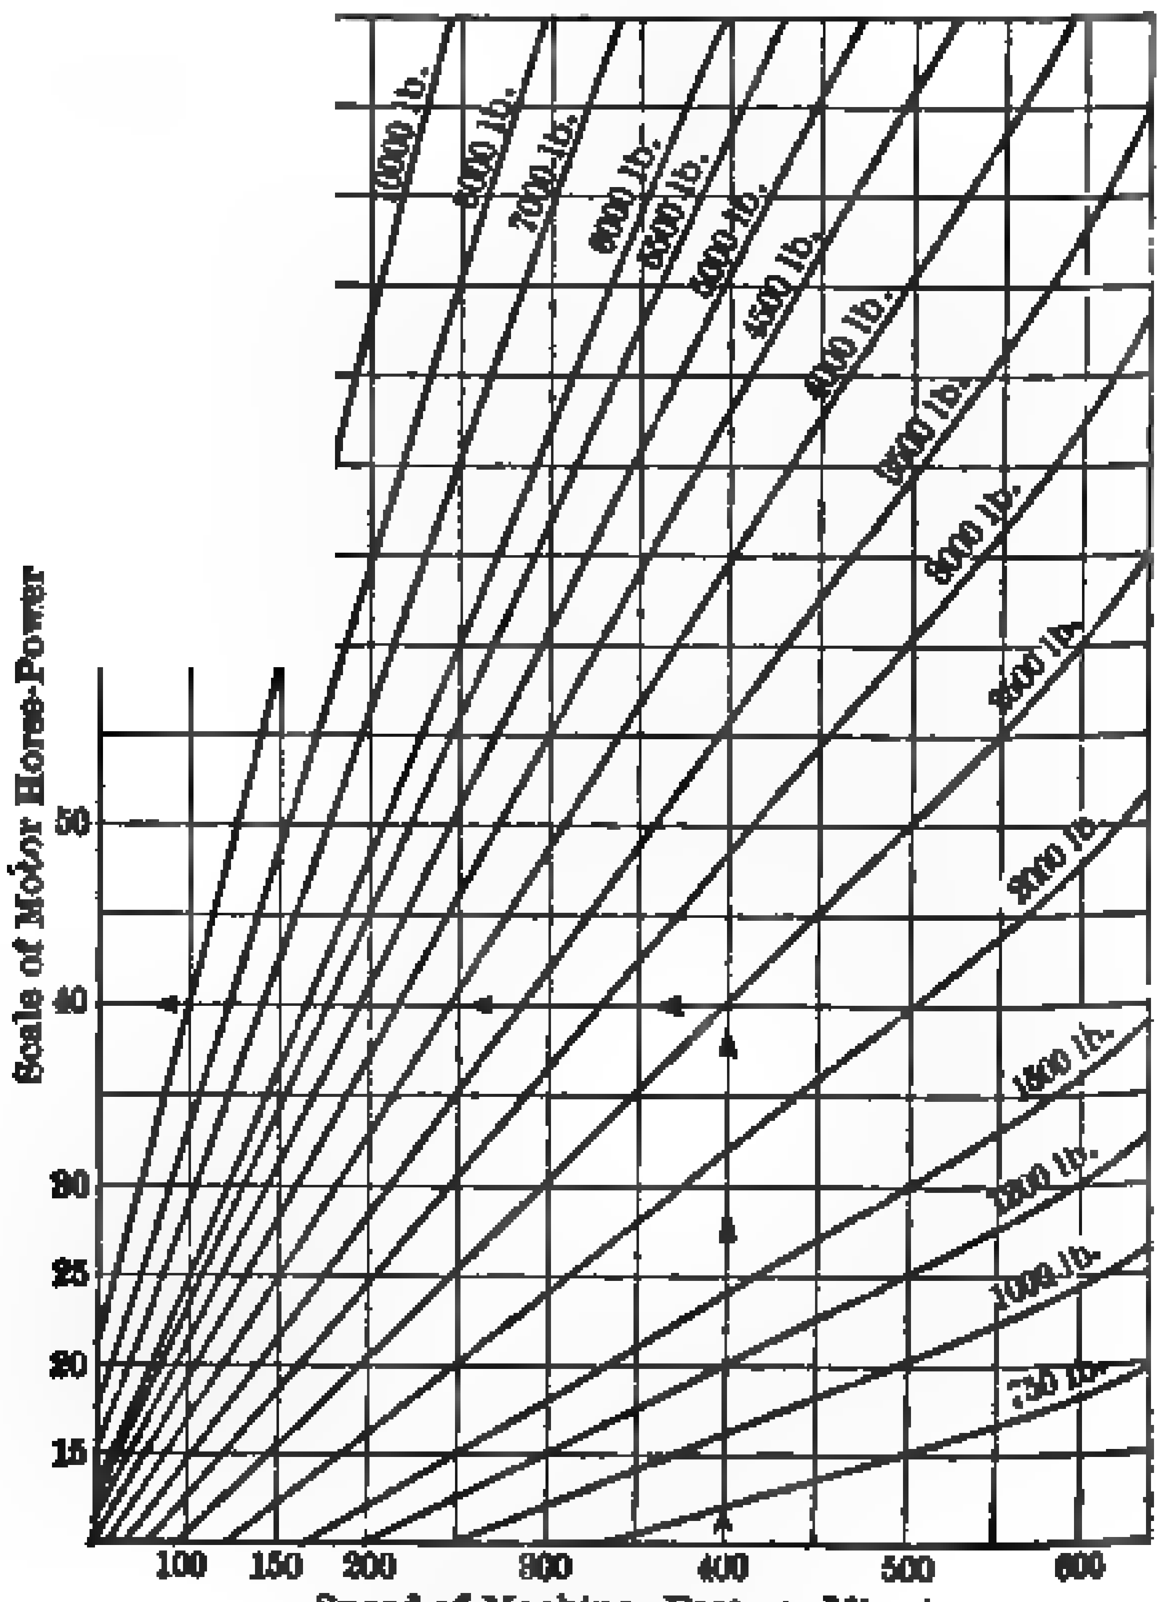

Fig. 8. Motor-sizes for Electric Elevators

Size of Motor. It is often helpful to be informed as to the SIZE OF MOTOR re-
uired for an installation, and the diagram (Fig. 8) may be used for this purpose.
or sake of illustration in the use of the diagram, a speed of 400 ft per min is
sumed, with a combined load of 2 500 lb. Following the line marked with an
row from the speed of 400 ft, the point of intersection is then at 2 500 lb. From
is point follow the line as indicated to the scale of motor-sizes, and the result
about 40 horse-power.

Table E. Current-Consumption

Motor-size	Starting-current	Running-current
20 horse-power	102 amperes	74 amperes
40 horse-power	202 amperes	147 amperes
60 horse-power	292 amperes	213 amperes

Current-Consumption. Table E gives the CURRENT-CONSUMPTION of motor-
es common in elevator-practice. The figures are for direct-current motors
erating at 230 volts and are based on the results of tests.

Electric Feeders. To aid in the selection of well-proportioned ELECTRIC
EDERS for elevator-motors, Table F is given. The figures are for 230-volt,
ect-current machines.

Table F. Wire and Conduit-Sizes for Electric Elevators, 2-Wire, 230-Volt, Direct-Current Systems

Motor-h.p.	Wire			Maximum run or distance for 2% drop, ft	Conduit		
	Size of each wire		Underwriters carrying capacity, amperes		Trade size for 2 wires	Inside diameter, in	Outside diameter, in

* Circular mils.

MAIL-CHUTES

General Description. This system of mailing letters by means of a specially
structed chute connected with the receiving-box at the bottom, has come
such general use in public buildings, office-buildings, apartment-houses
hotels, that the restrictions affecting the same and what is required in the
of preparation should be known to architects. The system is installed by
patentees, under regulations of the Post-Office Department governing its

construction and location, and for this reason it is well to consult the make before permanently locating the apparatus on the plans. It may be plac any building of more than one story, used by the public, where there is a delivery and collection-service, in the discretion of the local postmaster, sub to whose approval the contracts are made.

The Chute and Receiving-Box. The chute is required to be made with removable front and a continuous, rigid, vertical support is absolutely necess It must be of metal, its front must be of plate glass, and it must bear the insc prescribed by the department; and the whole apparatus, when erected and Government lock put on the box, passes under the exclusive care and contr of the Post-Office Department, and the chutes become a part of the receivi boxes. These boxes may be of various patterns and highly ornamented and a furnished by the makers in connection with the chutes. The work of prepari a rigid support for the chute and cutting and finishing the openings in the floo is of the utmost importance, and details showing the usual arrangements a always given.

Preparatory Work. The requirements for what the manufacturers ca PREPARATORY WORK include a flat, vertical, continuous surface not less tha

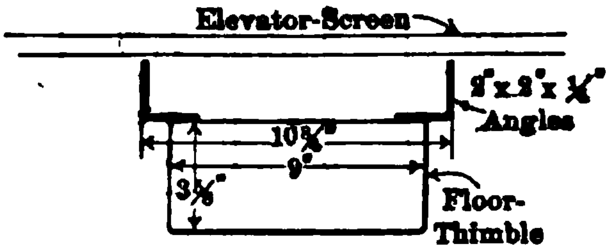

Fig. 3. Alternate Steel Support for Mail-chute

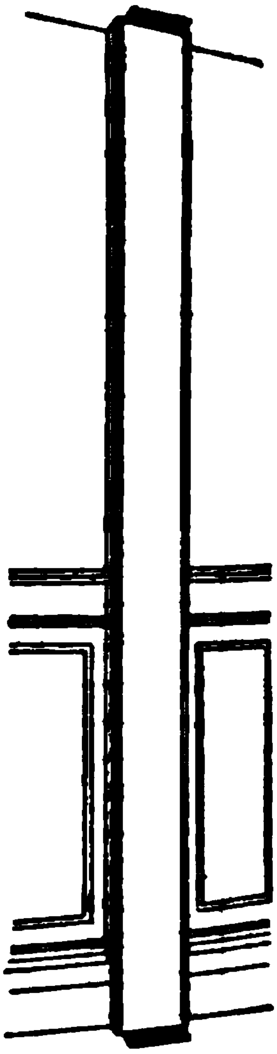

Fig. 4. Preparatory Work Complete for Mail-chute

10½ in wide, extending from the floor of the ground-story to a point 4 ft 6 i above the finished floor in the top story, and an opening in each floor direct in front of and centered upon this surface. These openings are neatly finishe and their size and shape determined by setting in them thimbles of iron whi

* The Cutler Mail Chute Company, Rochester, N. Y.

re furnished and delivered by the patentees, as part of their contract. In ordinary installations a casing of wood, suitably molded and finished to match the trim of the building, answers every purpose. Such a casing is shown in plan, Fig. 1, with the opening finished by the iron thimble. In buildings, or sometimes in a few stories, where a more elaborate finish is desired, marble is substituted for wood, the form and construction of the casing being adapted to the material, but of course without disturbing the size and form of the front surface. Steel angles are used where the use of wood is objected to, or where it is necessary to run the chute in front of an elevator-screen, or in other locations where a solid wall is not available to support the casing. Steel square-root angles, 2 by 2 by ¼ in in section, are generally used, and set as in Fig. 2, but sometimes, where it is desirable to fill up the space between them and the elevator-screen, they are reversed, as in Fig. 3. The angles are usually bolted to the beams, and in any case must be straightened so that they are without twists or kinks, and the surface which receives the mail-chute plumb and flush in all stories. Fig. 4 gives a general view of the mail-chute casings and floor-openings ready to receive the chutes themselves. This work of preparing the building, except the cutting or leaving ready the necessary openings in the floors, is now usually included in the mail-chute contract, as it has been found for many reasons undesirable to separate it. The necessary openings in floors, and all patching around such openings, should be included in the mason's or other proper specifications.

Essential Points to be remembered are (1) that no bends or offsets can be made, a vertical fall being absolutely essential, and (2) that the entire apparatus must be exposed to view and must be accessible, that is, it is not permitted to extend the work behind an elevator-screen or partition or through any part of the building except a public corridor.

REFRIGERATORS *

General Requirements. The following information is given as a guide to architects in providing for refrigerators in large residences, hotels, clubs, hospitals and other institutions. Consultation with a reliable refrigerator-builder, however, is always desirable before deciding upon spaces to be occupied by refrigerators, refrigerating-rooms, etc., as a satisfactory refrigerator cannot be adapted to a badly proportioned space. (See, also, Design of Refrigerators, under Mechanical Refrigeration, page 1691.)

Residence-Refrigerators. Care should be taken to select a refrigerator which is simple in operation and easily cleansed, as modern sanitary science has traced much illness to faulty refrigeration. Thorough insulation is an important feature in a refrigerator, as upon this depends economy in the use of ice and the securing and maintaining of the low temperature necessary to the proper preservation of food. Fig. 1 shows a kitchen-refrigerator for use of families of ordinary size. The ice-compartment is located in the middle division. The depth should not be more than 3 ft nor less than 2 ft, and the height may vary from 6 ft 6 in to 7 ft. The length of the front largely determines the capacity and should range from about 4 to 7 ft. Fig. 1 shows, also, a most satisfactory method of accomplishing the outside-icing feature which consists of a double outside icing-door complete, with frame and jamb. This is provided by the refrigerator-builder to fit the rough opening furnished by the owner in the outside wall of

* Valuable data and the drawings relating to this subject were furnished the author and editor by The Jewett Refrigerator Company, Buffalo, N.Y. Practical data were furnished, also, by The Brunswick-Balke-Collender Company, New York City. There are numerous other reliable firms whose refrigerator-work has the highest reputation.

the building. With this method a minimum outside opening is required to furnish a maximum inside opening for ice. The DRAIN-PIPES should be as short and straight as possible and should be readily detachable for cleansing purposes. The drain should be properly trapped in the floor of the refrigerator and carried through the floor of the building, discharging over the plumber's open connection as shown in the elevation of Fig 1.

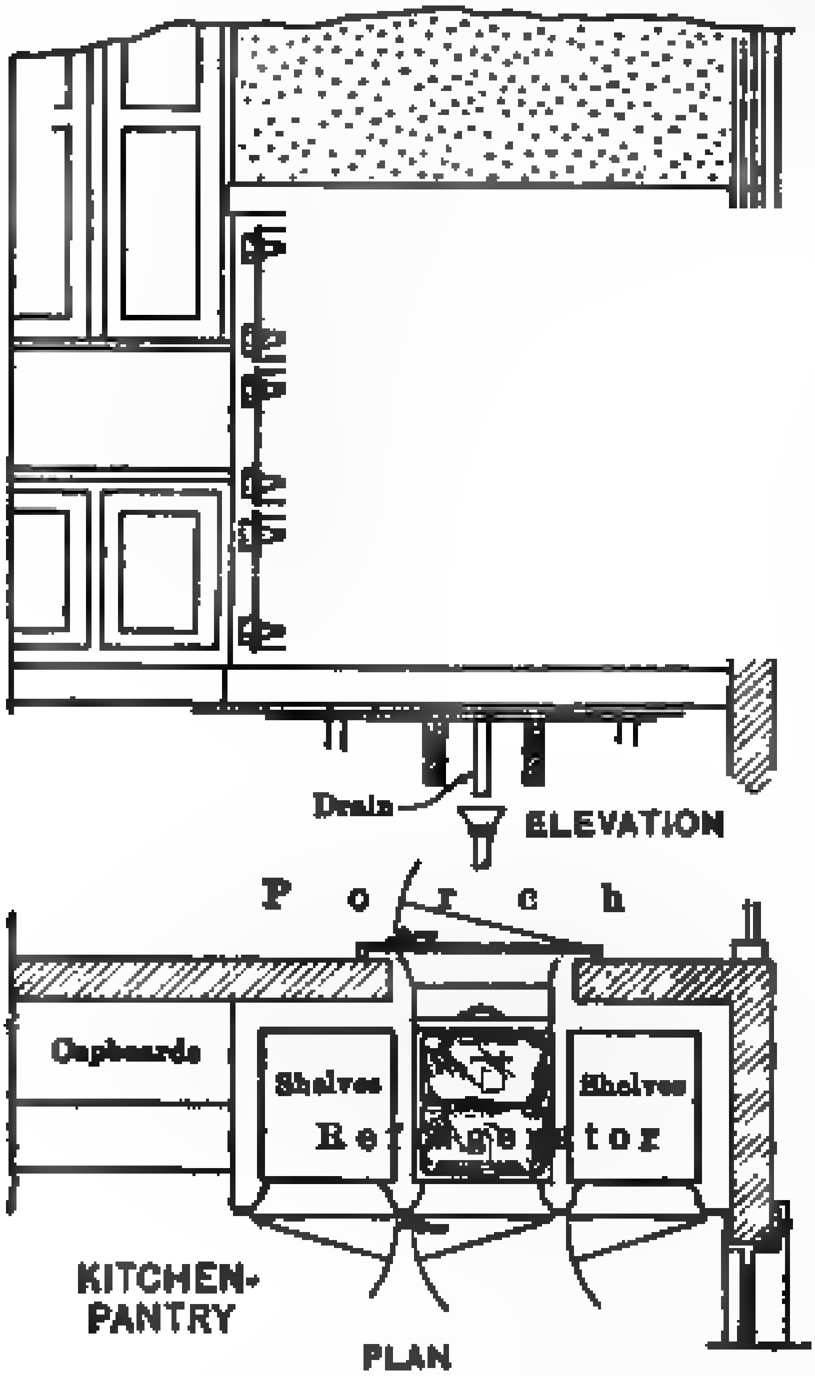

Fig. 1.* Kitchen-refrigerator for Small Family

Fig. 2 shows a refrigerator for use in a butler's pantry where economy of space is important. The ice-compartment is of galvanized steel throughout and is removable for convenience in filling as it slides on roller-bearing runways. When the ice-compartment is replaced in position the outside door closes over it. The adjoining storage-compartment is generally fitted with one removable shelf, below which is a bottle-rack for horizontally placed bottles and a space for standing bottles. The depth should be about 2 ft and the height 2 ft 4 in, under counter-top. The length of the front determines the capacity, but it should never be less than 3 ft. For a double refrigerator with a central ice-compartment and storage-compartments at either side, 5 ft is a convenient length. The exterior finish and hardware should correspond with the adjacent trim. The most sanitary and attractive interior finish for storage-compartments consists of white plate glass for the walls and ceilings and tile for the flooring. The usual complement of refrigerators for use in ordinary families consists of one adjacent to the kitchen and one in the butler's pantry. For large families the number could be the same with the capacity greater.

Refrigerators for Hotels, Clubs, Etc. MECHANICAL REFRIGERATION has largely superseded ICE as a cooling-agent where the refrigerator-equipment consists of several units, as in hotels, clubs and institutions. (See, also, Mechanical Refrigeration, page 1691.) The arrangement of refrigerators is similar to that employed where ice is used, as the refrigerating-coils are often contained in compartments corresponding to ice-compartments; the alternative method is to place the coils against walls of storage-compartments. Refrigerating-coils are generally of 1¼-in pipe, the length of coil depending upon the temperature required. Fig. 3 shows a practical layout for the working-department of

* The Jewett Refrigerator Company.

ɔd-sized club, and illustrates the proper complement of mechanically cooled rigerators, together with adjacent operating-equipment. No. 1, a store-room rigerator, has the front arranged in one full-height door and is fitted with three rs of shelves throughout. No. 2, a meat-refrigerator, is also accessible through ull-height door and is fitted with shelves and meat-racks. No. 3, a broiler d fish-refrigerator, has the front anged in two doors, each door ening onto a series of six galvanized eet-steel pans sliding on self-sustaining roller-bearing runways. No. a serving-pantry refrigerator, is ɔdivided by an insulated partition o three separate and distinct comrtments, those at the left and right ing each accessible through two ors, while the middle compartment accessible through one door, below ich is a series of four drawers ding on self-sustaining roller-bearing nways. The doors open onto reɔvable shelves throughout. No. 5, ice-cream refrigerator, occupies a sition in the serving-pantry counter d has the top arranged in one liftcover. Its interior fittings consist three 20-quart porcelain-lined iceeam jars and one glacé-frame for ncy forms of ice-cream. No. 6, a stry-refrigerator, has the front arnged in four doors, two upper doors ening onto removable shelving, and o lower doors onto pastry-pans ding on angle-iron runways. No. a bar-refrigerator, is subdivided by insulated partition into two separate and distinct compartments, each cessible through four doors. The upper doors open onto three tiers of movable shelves for standing bottles, while the lower doors open onto five rs of racks arranged specially for horizontal bottles. The equipment scribed above will also satisfactorily cover the requirements of a moderate-sized tel.

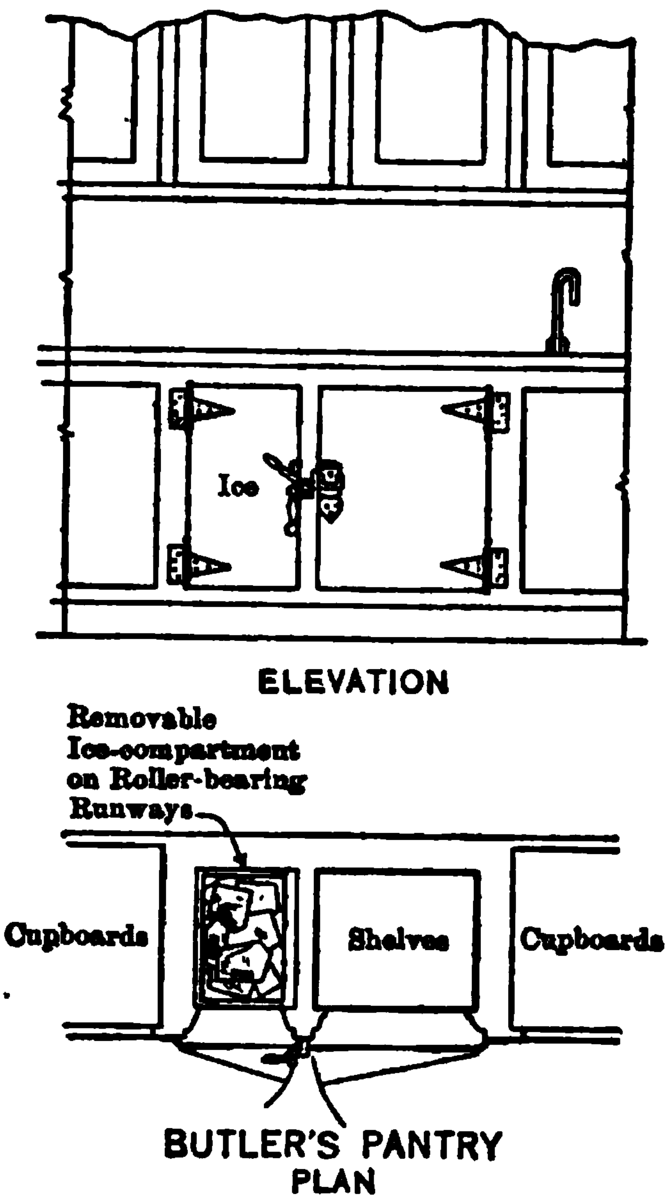

Fig. 2.* Refrigerator for Butler's Pantry

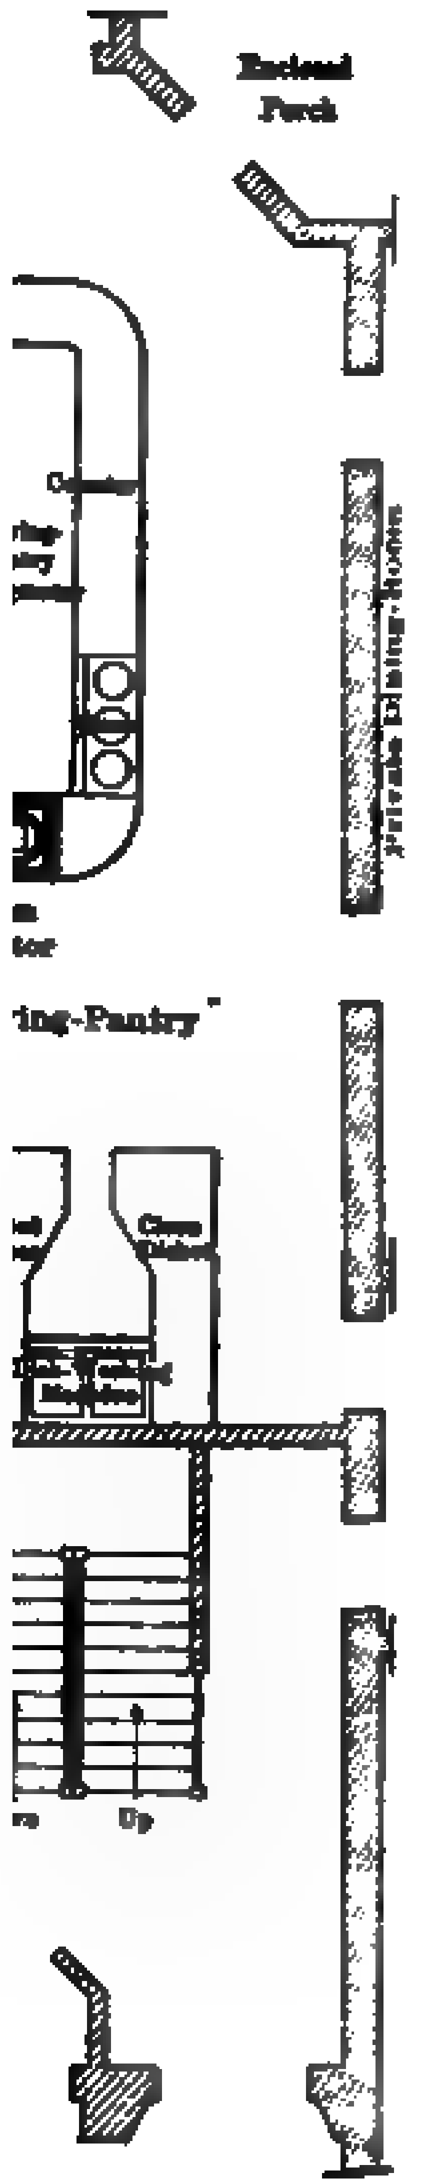
Refrigerators for Hospitals. The usual complement of refrigerators for nall hospitals consists of one large storage-refrigerator, one refrigerator for e chef's use in or near the kitchen, one for milk and butter and one iron-lined est for broken ice. For large hospitals the same number with increased capacity and with the addition of small diet-kitchen refrigerators, and possibly a ortuary-refrigerator for two or three bodies, will meet the requirements.

The Height of Large Refrigerators for hotels, clubs and institutions, to be tered through full-height doors, should be from 10 to 12 ft, if equipped with erhead ice or coil-compartments; with side ice-compartments or coils placed ainst walls, the height should be 7 ft 6 in or 8 ft. The smaller refrigerators,

* The Jewett Refrigerator Company



Main Dining-Room

Fig. 3.* Plan of Refrigerators for Large Club-house

* The Jewett Refrigerator Company.

cessible through half-height doors, hinged covers, drawers, etc., should be aced on a 3-in sanitary cement platform finished with cove to floor of building. nese refrigerators should not be higher than 6 ft 6 in unless provided with overad ice or coil-compartments, in nich case the height should be from to 9 ft.

Insulation. (See, also, The Value Good Insulation, page 1690.) efrigerators in modern hotels, clubs, stitutions, etc., are insulated with overnment-standard corkboard, the rge refrigerators being constructed 4-in cork throughout, in two courses 2 in thickness, and with all joints oken. Cork is applied to adjacent alls of a building with Portland ment, ½ in thick, and this cement used, also, in applying the inner ourse of cork to the outer course in alls, partitions and ceilings. All ork in the flooring is asphalted ater-tight. Interior finish may be Portland cement throughout or of lvanized sheets on walls and ceilgs and of Portland cement on floors. r the walls and ceilings may be of sed-on porcelain or white plate glass, nd the floors of tile, all depending pon the grade and character of the uilding to be equipped. The inlation of smaller refrigerators consts of (1) an exterior course of ⅞-in ngued and grooved lumber, (2) two ourses of water-proof insulatingaper and (3) a 3-in thickness of eet cork in two 1½-in courses, all oints being broken. To this insulaon is applied the interior lining.

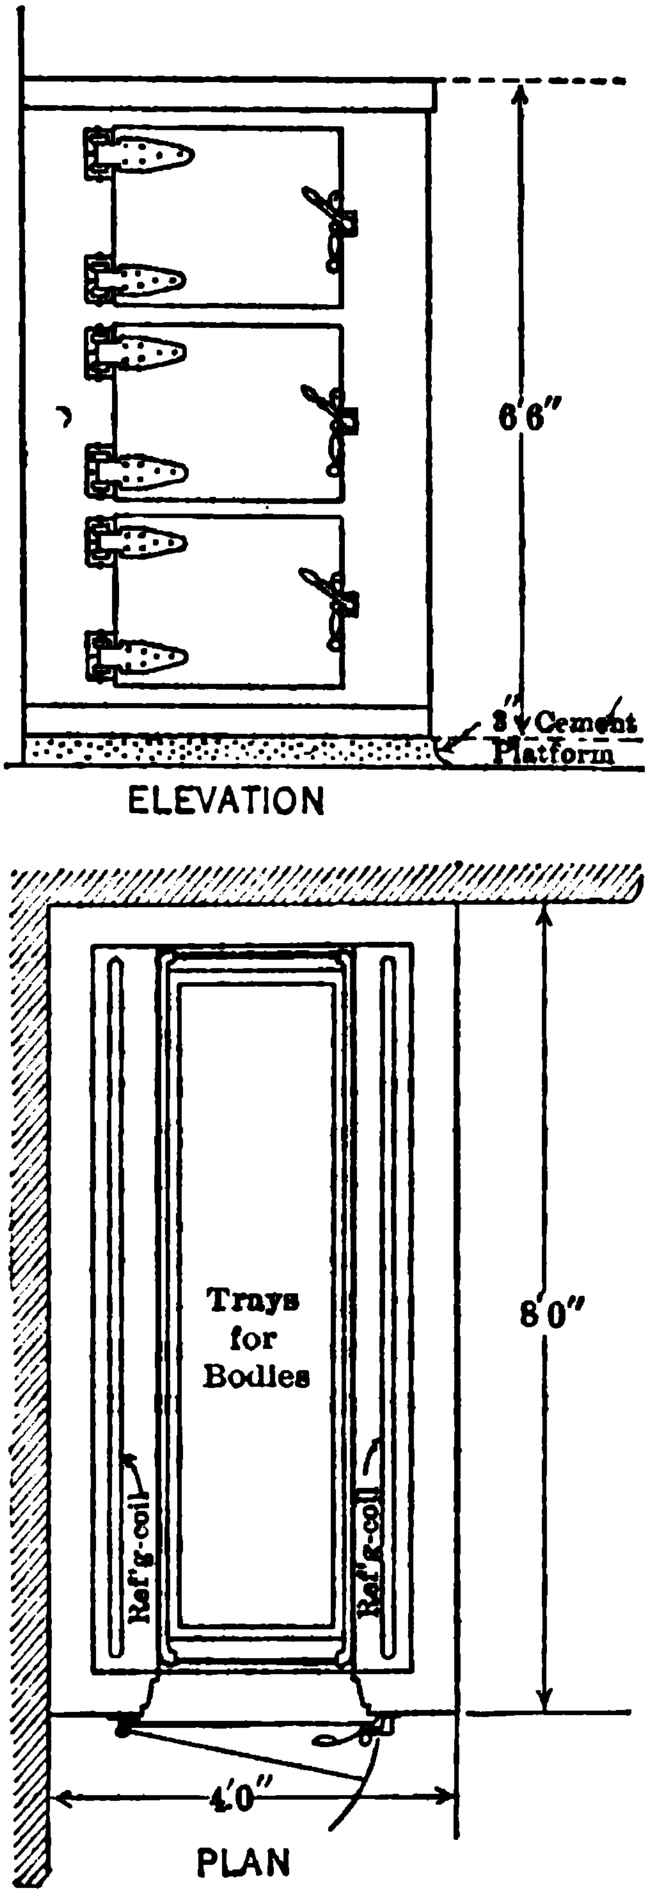


Fig. 4.* Mortuary-refrigerator

Mortuary-Refrigerators. Moruary-refrigerators should be cooled y mechanical refrigeration, the coils eing placed longitudinally on both ides of the mortuary-trays. Fig. 4 lustrates a mortuary-refrigerator for hree bodies. This may be used as a nit in designing mortuary-refrigerars of larger capacity, or the height ay be reduced to 5 ft and the odies placed in two instead of three orizontal tiers. Mortuary-refrigerators sometimes have both fronts finished nd equipped with doors so that bodies are accessible for identification or xamination from both fronts.

* The Jewett Refrigerator Company.

MECHANICAL REFRIGERATION *

A Brief Description of Methods in Common Use for Producing and Applying Refrigeration, with Special Reference to Small Plants

A British Thermal Unit, (Btu), is the quantity of heat required to raise the temperature of 1 lb of water 1° F. Heat used in this way, that is, to raise the temperature of water or other substance, is said to be present in that substance as SENSIBLE HEAT, or, in other words, heat, the presence of which we feel, or sense.

The Heat of Liquefaction, or so-called LATENT HEAT OF LIQUEFACTION of a mass of ice, is the amount of heat it will absorb in melting. One pound of ice at 32° F. will absorb 144 Btu in melting to water at 32° F. Heat coming into a cake of ice is thus absorbed in melting the ice and becomes what is known as LATENT HEAT, or heat absorbed without any rise in temperature. If the ice is at a lower temperature than 32° F., or if the water resulting from the melting rises above 32° F., additional heat will be absorbed as SENSIBLE HEAT.

The Specific Heat of a substance is the ratio of the quantity of heat required to raise the temperature of a certain weight of the substance one degree to that required to raise the same weight of water from 62° to 63° F.

The Heat of Vaporization of water or of any other liquid is the amount of heat it will absorb in vaporizing, in evaporating from a liquid to a gas, or will give out in returning from the gaseous to the liquid state.

Transfer of Heat occurs in three ways: (1) by convection, (2) by radiation and (3) by conduction. For instance, if particles of air in a refrigerator adjacent to a source of heat become warmed they circulate and distribute the heat by CONVECTION through the refrigerator-box. Heat will pass from a warm substance, as from the filament of an incandescent lamp, out into the box by RADIATION. Heat will enter the box through the walls by CONDUCTION.

Heat-Transmission. When the temperatures on opposite sides of any surface, as for instance, a wall, are unequal, heat will pass by conduction through the material from the warmer to the cooler side. The rate of this movement is the RATE OF HEAT-TRANSMISSION and is stated in terms of the quantity of heat called (Btu) which will pass through 1 sq ft of surface in 24 hours, per degree temperature-difference between the two sides of the wall.

Some Advantages Claimed for Mechanical Refrigeration.

(1) Lower temperatures can be obtained with refrigerating-machines than with ice.
(2) The inconvenience of handling ice is avoided.
(3) There is no accumulation of slime in the refrigerators as from the melting of even the best ice.
(4) Refrigerators cooled mechanically are dryer than ice-cooled boxes because the moisture is frozen out of the air and deposited on the cooling surfaces.
(5) There is generally a better air-circulation, resulting in a more uniform temperature and dryer atmosphere throughout the compartment.
(6) With proper design of refrigerator and refrigerating-machine any desired temperature can be obtained.
(7) Refrigeration produced mechanically is often cheaper than refrigeration produced by melting ice. (See page 1695.)

eration of Refrigerating-Machines. In almost all methods of producing advantage is taken of the fact that when a liquid evaporates it usually cools itself and its surroundings, and changes into a gas or vapor. There are al liquids which are easily made to evaporate and produce this cooling , and were it not for their cost, refrigeration could be very simply produced pplying a steady stream of the liquid and allowing the vapor or gas evapo- l to escape into the atmosphere. A refrigerating-machine is practically an ratus for saving this gas which has evaporated and returning it to its liquid to be used over again. In this process of recovery and condensation the gives out the heat which it has previously absorbed in evaporating. This is carried away by flowing water, which, in absorbing the heat, rises in erature.

ypes of Refrigerating-Machines. In the (1) COMPRESSION-TYPE of re- rating-machines the recovery of the gas is effected by drawing it away from oint where it has been evaporated and pumping it under increased pressure a chamber where it gives out its heat to the water-cooled walls of the nber and returns to the liquid state ready to be used over again. In the ABSORPTION-TYPE of refrigerating-machines ammonia is generally used and recovery of the gas is effected by bringing it into contact with water with h it unites chemically. The solution thus formed is pumped into another nber, and heat is applied to drive off the ammonia-gas which is then condensed r high pressure. It is now ready to be reevaporated and reproduce its cool- effect. In all cases of large units, and in all cases of either large or small s where exhaust-steam is available in sufficient quantities, absorption re- rating-machines are very economical.

quids Used in Refrigerating-Machines. A number of liquids have been l in refrigerating-machines, the ones commonly employed being (1) AM- IA, (2) CARBON DIOXIDE and (3) SULPHUR DIOXIDE. Various practical iderations determine which is to be used in any particular design of machine. h (1) AMMONIA the advantage is the lower working pressures, from 15 to lb per sq in, which are easy to deal with. An advantage over carbon dioxide at leaks are very easily located. Ammonia-fumes, however, are offensive sometimes dangerous in case of a break. With (2) CARBON DIOXIDE the antage is in its inoffensive odor. Its disadvantages are the high pressure at h it works, from 300 to 1 200 lb per sq in, the relative difficulty of holding e pressures and of finding small leaks, owing to its slight odor and chemical tivity. With (3) SULPHUR DIOXIDE the advantage is its comparatively low king pressure, which is not above 75 lb per sq in. Its great disadvantage is : with moisture it forms an acid which rapidly corrodes the apparatus. At time this disadvantage was fatal, since with the old-type machines, air and sture were constantly being drawn into the system more or less rapidly and ed with the sulphur dioxide. This difficulty has recently been overcome in e modern types of machines * in which the refrigerant is hermetically sealed he machine and chemical action, therefore, prevented.

ating of Refrigerating-Machines. A 1-TON REFRIGERATING-MACHINE is a hine which, if operated for 24 hours, will absorb the amount of heat which n of ice would absorb in melting. If the machine is operated a shorter time day, a less amount of heat will of course be absorbed, and in order to main- the temperature during the period when the machine is not running, some

The Audiffren Refrigerating-Machine, a small machine intended for domestic uses manufactured by Johns-Manville, Inc., New York. There are many other reliable s making refrigerating-machines of other distinct types, and the architect should carefully into the merits and claims of each when called upon to specify them.

means must be adopted for storing cold. (See paragraph below.) Refrigera machines are sometimes rated in terms of ICE-MAKING CAPACITY, that is, in of the amount of ice the machine will make in 24 hours. This is always less the refrigerating capacity because some refrigerating effect is required to the water down to 32° F. before the freezing can begin, and the ice is us cooled several degrees below 32° F., which requires a still greater capacity. Th is also some flow of heat into the apparatus. These elements vary consider so that from some points of view ICE-MAKING CAPACITY might be considered unsatisfactory method of rating some refrigerating-machines.

Applying the Cold. According to one classification there are three com systems of applying the cold. These are, (1) the DIRECT-EXPANSION SYS (2) the BRINE-SYSTEM and (3) the COLD-AIR SYSTEM.

(1) In the DIRECT-EXPANSION SYSTEM the refrigerant is evaporated in a of pipe placed directly in the room to be cooled.

(2) In the BRINE-SYSTEM the refrigerant is used to cool brine, which is th circulated through coils of pipe in the room to be cooled.

(3) In the COLD-AIR SYSTEM a current of air is chilled by passing it over of pipe cooled directly by the evaporating refrigerant, or by brine, or passing it through a spray of cold brine; and this chilled air is then passed i the room and circulated back to the cooling-coils, the whole operation be repeated indefinitely.

All of these systems have their advantages and disadvantages. While t brine-system is a little more expensive to operate in large plants, the temp ature is more easily controlled than with the direct-expansion system, and practice in small plants it is found as economical in operation in spite of i theoretical disadvantage. Furthermore, in case of any breakdown in the m chine, the temperature can be held for a time by circulating the brine until becomes too warm to be of use, whereas with direct expansion the temperat will begin to rise immediately upon the stopping of the machine. The cold system is not as applicable where any drying of the goods stored would be har ful and there is some risk of carrying fire in the air-passages. It is much us nevertheless, for such service as chocolate-dipping rooms, ice-cream harden fur-storages, etc.

Storage of Cold. When temperatures are to be maintained while the refri erating-machine is shut down, COLD must be STORED. In the brine-system t is effected by cooling a comparatively large body of brine which warms slo as it is circulated. Where the brine-circulating pump as well as the machi must be stopped, so-called PRESSURE-TANKS may be placed in the pipi system in the room being cooled; the mass of brine in these tanks absorbs t heat and helps to maintain an approximately even temperature. Where th direct-expansion system is used, a part of the cooling-coils may be immersed i a tank of brine placed in the room and the remainder of the coils arranged f the direct cooling of the room. In some places the spaces available will n permit the use of brine-storage tanks. In cases of this kind smaller tanks m be used and filled with water, or a weak brine which will freeze at a tempera ture a little below 32° F. Since 1 lb of ice in melting will absorb 144 Btu an 1 lb of brine rising in temperature, say 20°, will absorb only from 14 to 16 Bt the saving of space is apparent. It must be absolutely certain that the refri erant reaches the tank first at the bottom and that the air to be cooled reach it first at the top so that the ice in forming shall not bulge or burst the tan If the congealing mass were to freeze from the top down the tank would b strained and finally leak, because of the expansion of the ice in freezing. A other fact to be considered is that where water, only, is frozen, a resulting hi

mperature may be obtained in the refrigerator, since the brine must be armer than the ice in order to melt it, and the refrigerator just that much armer, or warmer than an ice-cooled box. In calculating the proper sizes of nks for storing brine, it should be remembered that, usually, the period during hich the machine is shut down coincides with the period during which the mand for refrigeration in the box is the least. The amount of heat to be sorbed is usually only that entering through the insulation, as the doors are ut and no food is put in or removed.

Description of Refrigerating-Machines. As explained in the preceding ragraphs refrigerating-machines may be divided generally into two classes,) the COMPRESSION-TYPE and (2) the ABSORPTION-TYPE.

(1) **The Compression-Type of Refrigerating-Machines** may be subdivided as llows:

(*a*) The open type of machine, which is made both vertical and horizontal, d both single and double-acting, that is, compressing the gas at one end or both ends of the cylinder. (*b*) The partially enclosed type of machine, in hich all the moving parts of the compressor proper are enclosed within the frame the compressor, except the fly-wheel and the main shaft which enters the ame of the machine through a stuffing-box. Such valves, also, as are required the system are exposed. (*c*) The wholly enclosed type of machine,* in which l of the working parts are enclosed in a hermetically sealed container.

(*a*) One advantage of the open type of machine is that any lack of adjustment e to wear can be readily corrected; so that, with proper attention, it gives cellent results. For large installations this is considered by many to be a ost efficient type of machine.

(*b*) The enclosed type of machine resulted from the effort to reduce the amount attention required by the open machine, to cheapen its construction and to duce the possibility of trouble from inexpert tampering. An objection to achines of this type is that when adjustments have to be made the working rts are relatively inaccessible.

(*c*) With the wholly enclosed type of machine it is claimed that the loss of e refrigerant is prevented by the hermetical sealing of the apparatus, and that e working parts, being completely enclosed, are protected from deterioration e to outside causes or tampering.

(2) **The Absorption-Type of Refrigerating-Machines** are of two kinds, differ-g principally in the proportioning of the parts. In the one machine high-pres-re steam is used; in the other the proportions are such that low-pressure exhaust-steam may be used. Where exhaust-steam is available machines this type are found to be very economical, and this is true, also, for all large its whether or not exhaust-steam is used. Full descriptions of these machines ith detailed plans and layouts may be obtained from the various manufacturers.

Calculations for the Capacity of a Refrigerating-Machine. Heat enters e refrigerated compartments, (1) through the walls, (2) with warm goods, (3) the interchange of the outside air when doors are opened and by air-leaks, nce the cooled air is the heavier and immediately flows out when a door is ened, (4) from lights or from the heat of the bodies of workers, and (5) om any change of state occurring in the goods, such as freezing, fermenting, c. In large rooms these various sources of heat should be analyzed sepa-tely. In small refrigerators, as in hotels, kitchens, dwellings, etc., a rough le, quite as accurate as a more elaborate analysis, allows a certain number of tu per cubic foot of refrigerated space per 24 hours. This amount varies

* Referred to on page 1685.

with the character and location of the box, the nature of its insulation, the temperatures desired and so on. It will be seen that the insulation, while of great importance, is not by any means the only important factor in this class of boxes. For domestic refrigerators in which a temperature of from 35 to 50° F. is maintained, 300 Btu per cu ft of refrigerator per 24 hours should be allowed. For boxes in hotel or restaurant-kitchens, 600 Btu, or even 900 Btu in extreme cases and where low temperatures are required, should be allowed. For butchers' coolers or large storage-boxes in hotels, etc., from 200 to 250 Btu per cu ft per 24 hours should be allowed. A check on the above figures for the large type of box is the following: * "When the exact conditions under which cold-storage rooms are to be operated are known, namely, the size and shape of the rooms, the quality of the insulation, the kind and quantity of goods to be handled per day and the temperatures at which they are received and at which they are to be held, the amount of refrigeration required can be estimated very closely by the following rule: (1) Calculate the exact area of exposed surface in the walls, floor and ceiling of the room in square feet, multiply the total number of square feet by the number given in the table for the required temperature and divide the product by 288 000. (2) Multiply the amount of goods in pounds, to be stored per day by the number of degrees of heat to be extracted by the specific heat of the goods, and divide by 288 000. This will give the amount of refrigeration, in tons per day, necessary to maintain the temperature required for the goods. (3) Add these two amounts together. The total will be the amount of refrigeration, in tons per day, required to maintain the temperature required for the goods and for the room. (4) If the goods are to be frozen, the latent heat of freezing should be added to the number of Btu to be extracted."

For rooms containing less than 1 000 cu ft	
If maintained at 0° F. multiply the exposed surface by	1 775
If maintained at 5° F. multiply the exposed surface by	710
If maintained at 10° F. multiply the exposed surface by	535
If maintained at 20° F. multiply the exposed surface by	355
If maintained at 32° F. multiply the exposed surface by	265
If maintained at 36° F. multiply the exposed surface by	180
For rooms containing from 1 000 to 10 000 cu ft	
If maintained at 0° F. multiply the exposed surface by	1 250
If maintained at 5° F. multiply the exposed surface by	600
If maintained at 10° F. multiply the exposed surface by	300
If maintained at 20° F. multiply the exposed surface by	190
If maintained at 32° F. multiply the exposed surface by	160
If maintained at 36° F. multiply the exposed surface by	125
For rooms containing more than 10 000 cu ft	
If maintained at 0° F. multiply the exposed surface by	1 100
If maintained at 5° F. multiply the exposed surface by	550
If maintained at 10° F. multiply the exposed surface by	275
If maintained at 20° F. multiply the exposed surface by	180
If maintained at 32° F. multiply the exposed surface by	140
If maintained at 36° F. multiply the exposed surface by	110

* Taken from Levey's Refrigeration Memoranda, page 41.

With small machines it is necessary to allow a greater capacity of machine : a given size of box than with large machines, since, with the latter, one can vays throw a large part of the machine-capacity to any given box where ɔcial need may exist; whereas to do this with the small machine would almost tainly rob some other box, if indeed there happened to be another box. It is ver possible to determine with mathematical certainty exactly how much rigeration is required for a given case. It is best to allow for this fact and be sure the machine is amply large. Where an existing ice-cooled box is to cooled mechanically one check upon the size of the machine required is the ount of ice used. This check is more apt than any other, however, to lead erroneous conclusions unless the figures are properly analyzed.

Another Method of Determining the Capacity of a Refrigerating-Machine. e following is a method that gives good results, except that allowance may be de in the larger boxes and where brine-storage tanks are provided in the box the steadying effect of the mass of cold brine:

(1) The ice-consumption for the hottest month of the year should be deter-ned. This will give the average ice-consumption for that month.

(2) The average temperature that is maintained in the box with ice should n be accurately determined. This will usually be from 55 to 65° F. It will nmonly be stated to be anywhere from 40 to 45° F., but these temperatures : seldom obtained. Even if they are, with a full ice-chamber and the box sed for long periods the average will be above these figures. Unless, there-e, there is positive assurance to the contrary, from 55 to 60° F. should be sidered the average temperatures.

(3) A calculation should then be made of the heat-inflow through the insula-n, with a temperature of 55° F. in the box and with the average summer nperature outside. The difference between the heat-inflow through the ulation and the total heat actually absorbed by the melting of the ice is the ount entering the box from other sources than through the insulation. This ess of heat ordinarily occurs during the hours of daytime only, that is, when : box is being opened, since at night the box will remain closed. A machine sufficient capacity to produce the temperature actually obtained with ice st, therefore, be of larger rated capacity than that indicated by the actual -consumption; and how much larger it should be can be determined by this thod.

(4) A further fact which it is claimed should be taken into account in deter-ning the proper size of a machine is that temperatures obtainable with ice : often unsatisfactory. If they were always satisfactory one reason for put-g in cooling-machinery would be done away with. Where 55° F. is obtained h ice, from 35 to 45° F. will be required with mechanical cooling and the chine-size must be further increased in the ratio of the temperature-differ-es between average summer temperatures and 35° F., and average summer nperatures and 55° F.

(5) The cooling-machine if installed in accordance with these figures would ndle average-weather conditions but would not be adequate for extreme -weather conditions, the most important conditions to be met by cooling-chinery. It is necessary, therefore, to further increase the size of the machine the ratio of the difference in temperature between maximum summer tem-ature and 35° F., and average summer temperature and 35° F.

(6) A further allowance should be considered, namely, the fact that in many es, for one reason or another, it is not possible, or else not desirable, to oper-the machine except during certain periods of the day, and the machine-size st be increased as much as may be required to take care of these conditions.

(7) If the machine is not placed directly at the box to be cooled, allowance must be made for the heat-inflow into the insulated brine-mains. The amount of heat entering from this source is often of considerable importance, particularly with small machines. The table below gives heat transmissions for cork pipe-covering and some other materials.

Water and Milk-Cooling. Mechanical refrigeration as applied to cooling water and milk differs in one respect from other classes of refrigerating-work. A relatively intense quantity of cooling effect is called for in a brief interval of time. For instance, in a drinking-water system the heaviest requirement may come at the noon-hour. In a bakery, also, the demand for chilled water will be intermittent, a large quantity of water being required for the dough mixing. In dairy-work the milk must be cooled very rapidly to check the development of bacteria which grow with incredible rapidity within the temperature-range of from 110 to 50° F. To install a large enough refrigerating machine to produce the required cooling effect as it is needed would in most cases call for a very large machine. This is overcome by using a small machine and allowing it to operate for a longer time, say throughout the day, storing the refrigerating effect produced by cooling a large body of brine or melting the ice as rapidly as may be required. For instance, if 50 cans of milk, of 40 qts each, are to be cooled from a temperature of from, say, 75 to 35° F., in 1 hour, the refrigeration required will be 50 cans times 40 qts times 2 lb per qt times (75° F. − 35° F.), which equals 320 000 Btu. Milk is treated in the calculation as having the same specific heat as water, since water is so large a percentage of its total weight. This amount of refrigeration produced by a machine running 12 hours per day would require the machine to absorb 320 000 Btu divided by 12, or 26 000 Btu per hour. The quantity of brine necessary to store the cooling effect may be calculated closely enough for practical purposes by using the following approximate figures. The specific heat of brine is 0.75. The weight of the brine is 9 lb per gallon. The permissible temperature-range of the brine depends upon the conditions and may be from, say, 30 to 15° F., or lower. In other words, the temperature to which the brine can be permitted to rise is limited to the temperature it must produce in the room or in the substance being cooled, and the temperature to which the brine can be cooled in storing cold is limited by the decrease in economy of the refrigerating-machine at the low temperatures.

The Value of Good Insulation. (See, also, Insulation, page 1683.) The importance of good insulation cannot be too strongly emphasized. A cold-storage room or refrigerator and its contents may be cooled by ice or mechanical means, but unless the walls are adequately insulated, the demand caused by the inflow of heat through the poor insulation may be more than the ice supply or refrigerating-machine can meet to maintain the required temperature. The almost universal standard of insulation for cold-storage rooms is 4-in thickness of pure-cork sheet. The following table shows the heat transmitted through 1 in in thickness of each of the substances, per square foot of exposed surface per degree difference in temperature per 24 hours.

Pure-cork sheets	6.4 Btu
Hair-felt	7.3 Btu
Impregnated cork boards	8.5 Btu
Rock-wool blocks	8.0 Btu
Waterproofing lith-blocks	8.5 Btu
Spruce, clear and dry	16.0 Btu
White oak	26.0 Btu

Design of Refrigerators. Disposition of Cooling-Surfaces. (See, also, bject of Refrigerators, page 1679.) No attempt need be made to describe all the many arrangements of refrigerated compartments that are to be found in rvice. The intention is to point out some of the more important things to considered in determining upon the design of a box. It is desirable in a rigerator to produce not only a low temperature, but a relatively dry atmosere.

Cooling-Surface and Temperature. Securing the low temperature is merely question of supplying sufficient cooling-surface to produce the desired results th the temperature available in the refrigerant. The amount of surface quired is influenced by the arrangement of the box, that is, whether or not e air passes freely or sluggishly over the surface, whether the cooling-surface placed on the ceiling or walls of the compartment or in a loft and, if the latter rangement is used, whether or not the air-passages are of proper size and the culation between the loft and the compartment sufficient.

Dryness of Atmosphere and Temperature. To secure a box of satisfactory yness it is necessary to have a relatively low temperature in the refrigerant. e air which passes over the cooling-surfaces is practically in a saturated conion when it leaves them. If it is to be dry at the temperature required in e box, it must have been, necessarily, cooled well below the box-temperature. r instance, in a box, the temperature of which is maintained at 35° F., the ne should be run at a temperature of from about 20° to 25° F. It is further sirable to so locate the cooling-surface that frost in melting will pass out of e box quickly and not remain to be reabsorbed by the air in the box.

Arrangements of Cooling-Surfaces. There are several common arrangements cooling-surfaces in refrigerators. Sometimes the coils are arranged overhead, t directly in the compartment to be cooled. This is one of the efficient ways which a cooling-surface can be arranged, so far as the cooling effect alone is ncerned. It is not, in general, a good arrangement, however, since frost lting from the coils drips on the goods. In another arrangement the coolingfaces are on the wall. This is preferable to the ceiling-arrangement, as far the dripping is concerned. The objection to it is that goods placed close to e walls are apt to be overchilled, while goods nearer the center of the comrtment are not cooled quickly enough. It also wastes floor-space, because cking goods close to the coils is not practicable on account of possible overlling and also on account of the liability of retarding the air-circulation. The ll-arrangement for cooling-surfaces is, nevertheless, often the most practica- method. Another method involves a modified form of wall-coil arrangement which a brine-storage tank is used to assist in maintaining the temperature en the machine is shut down. A further modification is often introduced, which a partition or baffle-plate is used in front of the coils. The best types box-arrangement are those in which the cooling-surface is separated from the rage-space and is so arranged as to secure an active circulation of the air r the coils and through the compartments. In all of these plans the one quirement calling for the greatest care is that the air-passages shall be as ect as possible and of ample size. The force causing the air to circulate, nely, the difference in weight due to differences in temperature and density tween the column of air in the coil-compartment and that in the storagempartment, is so extremely small that any slight interference is a serious tter. An extra turn in the passage or a slight reduction in the size of the ssage will produce a marked effect. A good rule to follow is to make the ssage as large as it can be made without allowing any drip to reach the rage-compartment. This will work out in many cases to show a ratio of

1 to 8 or 9 between the area of the passage and the floor-area of the com-ment; but even 1 to 6 is just that much better if it can be secured. The mat of proportioning the size of the air-passages is of much less importance wh the air is circulated by fans. Forced circulation is not usual, however, ex in large storage-refrigerators, and no attempt will be made here to consid One precaution that must be taken in arranging the cooling-surface, especi in small and frequently opened boxes, is the avoidance of any undue cooling walls or ceilings that are exposed to currents of warm air when the do opened. Moisture from the incoming air deposits on these surfaces and ca the offensive so-called SWEATING of the box. This is most often seen on t storage-compartment side of uninsulated coil-compartment floors or partiti and also occurs on walls or ceilings where the cooling-pipes are set very close these surfaces. The obvious and effective cure is to insulate the partiti between coil-compartments and storage-compartments and keep cooling-s faces well away from walls or ceilings, from 3 to 8 in, depending upon the te perature of the brine.

Incidental Notes on Refrigerators. Drawers. In restaurant-kitch and elsewhere it is sometimes convenient to have a box fitted with a numb of refrigerated drawers. The heat-leakage through the many joints, throu slides which are invariably only partially closed, and through the poor insul tion of the drawers, is very great. Where it is at all possible to do so, it best to arrange an insulated door covering the entire drawer-space.

Anterooms. In storage-rooms of medium to large size the air-interchan due to opening doors is reduced to a minimum by arranging an anteroom entry which, after it is entered, has its outer door closed before the door to t storage-room proper is opened. Where two rooms are side by side, it is oft possible to reduce the interchange of air by treating the one room as an an room of the other, having but one door to the outside air.

Doors. Special note should be made as to the design of doors for refrigera rooms or boxes. There is a common idea that a refrigerator-door should beveled. As a matter of fact no more certain means of ensuring air-leak could be devised. A perfectly fitted beveled door, hung accurately in pla could perhaps be made tight in the beginning. This door in service at on begins to sag, since a refrigerator-door is always heavy. It immediately b comes impossible to force it to a tight seat and continuous leakage of air begi A refrigerator-compartment door is most readily made tight by having a f surface on the door come up against a corresponding surface on the frame, wi a soft gasket of some kind between them. There are several well made r frigerator-doors on the market at prices low enough to make it doubtful econom to attempt the home-made article.

Arrangement of Brine-Mains. In laying out mains to carry brine from th refrigerating-machine to the refrigerator, there are a few simple points to b cared for. For the convenience of the pipe-covering man, the flow and retu lines should be placed far enough apart so that he can get his covering on each pipe without cutting it to pieces, or else they should come close togeth so as to be covered together. A common difficulty experienced in brine-sy tems of refrigeration, where the cooling-coils in several compartments are fe from the same main, is that when the adjustment of the valve controlling th flow of brine through one coil is changed, it upsets the adjustment of the whol system. This is due to too small mains or too small a pump, or both. A similar action is observed when the opening of a faucet on a water-pipe chec the flow from other open faucets on the line. The ideal cross-section area o

brine-mains is as nearly as possible equal to the combined cross-section of the coils which they serve at any one time. Even with this proportion, ever, it is not possible to absolutely ensure that the lower coils will not rob upper ones, or even drain them completely in some systems of piping. A effective, even if somewhat expensive method of overcoming this diffi-, is by the addition of a third main. In this arrangement it is not possible ne coil to rob another to the point of draining it.

alculations for the Necessary Amount of Cooling-Surfaces. No and fast rule can be given regarding the proper amount of cooling-surface compartments of various sizes, since the design and arrangement of the ng-surface and the freedom with which the air circulates over it greatly t the amount required. As a general guide, however, and where the con-ns are such as to permit a good circulation of the air, the following formula give good results. It will be understood, of course, that the refrigeration ired in the given room has been determined as previously indicated. cooling-surface required, in square feet, per ton of refrigeration equals $0/(T - t)$ in which T is the temperature desired in the compartment, and t average temperature of the brine.

e-Making. If the following facts of physics are kept in mind in consider- methods of making ice the results obtainable may be understood or pre-ed:

(1) Chemically pure water will freeze solid and clear.
(2) Water containing impurities in solution tends in freezing to force th impurities out of solution. The slower the process of freezing t more completely is the purification effected.
(3) Ice forming in still water sends out long slender crystals which incre in number and size, forming a meshwork that gradually becomes solid mass.
(4) Agitation of water during freezing aids in the separation of impuri and therefore in forming solid, clear ice.
(5) Practically all natural waters contain more or less organic or inorga material in solution and invariably contain air in solution. Th substances are, therefore, frozen out of solution and tend to cause t ice formed to be opaque, the lighter substances tending to rise a collect near the surface, and the heavier ones tending to sink.
(6) The rate of freezing of ice decreases as the thickness already form increases, so that the time required to freeze increases as the squa of the thickness to be frozen. In the formation of natural ice t freezing is from the top down and impurities frozen out of solution fi This and the motion of the water, especially in quiet running strea tends to make naturally frozen ice transparent. American manuf turers of ice have always tried to duplicate this clearness.

Methods of Ice-Making. The method first adopted in this country was t one in which DISTILLED WATER was used. From a sanitary point of view su ice would be theoretically ideal. Practical difficulties make it almost imp sible to secure pure ice in this way. Some of these difficulties are:

(1) Removal of oil from the distilled water, this oil being picked up as t steam passes through the cylinder of the engine. It is difficult remove organic oil which is present in the lubricant.
(2) Assurance that the filters are in proper shape, an assurance often imp sible to obtain since this apparatus is ordinarily used the season throu without overhauling.
(3) Possibility of contamination in the storage-tank where the distilled wat is held and usually PRECOOLED to as near 32° F. as possible, befo passing to the freezing-cans, thus saving time in the freezing proc in the tank.
(4) Possible contamination from handling the cans and the wooden cov over them. These covers form the top of the freezing-tank in whi the cans of water are immersed in cold brine for freezing and a tramped over by the ice-harvester with the consequent possibility dirt getting into the cans.

A second system of ice-making in common use in this country is the PLA SYSTEM. In this process the ice is formed on vertical steel plates. Natu or raw water is used and the bath is agitated by various methods. The r sulting ice is very clear and dense. In this system when the ice is formed the desired thickness, usually about 12 in, it is loosened from the freezi plate by various thawing-arrangements in different forms of the apparatu The ice-plates, often 9 by 16 ft by 12 in in thickness, are lifted from the tan by overhead cranes and carried to a table where they are cut to commerci sizes. While the plate process is usually very slow on account of the f that the freezing is from one side only, it is largely used and lends itself to gr economy in steam-consumption, whereas in the old-style distilled-water i making plant the amount of steam required to make the ice was more than t

nomical engine would use and it was not possible to obtain fuel-economy. e modified form of this system, now coming into considerable favor, is anged so that STATIONARY CANS are filled with raw water and kept agitated compressed air bubbling up through it. When the freezing has progressed newhat the remaining water is drawn off and replaced by fresh water, thus noving the greater part of the impurities that have been frozen out of solu-n. Various other modifications of these two systems of ice-making have been l are being developed. All of them depend, however, upon the series of ysical facts stated in the preceding paragraphs, and the results may be lyzed by reference to them.

Relative Economy of Producing Refrigeration Mechanically and by . (1) In determining the cost of REFRIGERATION BY ICE, account must taken not only of the cost of the ice but of melting, of the uncertain ice-vest, of the amount of ice left over at the end of the season and of that zen together in the storage and, therefore, practically useless. Regarding melting, it may run anywhere up to 50% of the total ice-harvest. The antity left over at the end of the season is, of course, so variable that it is possible to estimate it, this being purely a matter of chance. In many es, however, it is a very large item. The loss by the ice freezing together the storage can be reduced to a very small amount where the ice is properly ked with distance-strips between the ice-cakes. Proper packing is much re readily carried out, however, where artificial ice is stored than where ural ice is held, and a mechanically cooled ice-storage is less subject to this iculty, since the temperature is, of course, constantly held below the melting-nt of ice. (2) The total cost of REFRIGERATION PRODUCED MECHANICALLY ludes the cost of power, water, oil, refrigerant (usually ammonia), labor l attendance, and interest and depreciation on the investment. The figures these items vary between wide limits. The following figures, however, will of interest. Care should be taken in drawing conclusions from them as to t in prospective installations. These figures are from the annual cost of an -manufacturing company having a capacity of 1 500 tons per day in plants ging in size from 50 to 100 tons per day each.

Coal	40 cts per ton of ice produced.
Labor	50 cts per ton of ice produced.
Ammonia	10 cts per ton of ice produced.
Water	5 cts per ton of ice produced.
Waste, power, oil, etc	10 cts per ton of ice produced.
Total	$1.15 per ton of ice produced.

TOWER-CLOCKS *

Rule for Diameter of Dials. "To look well and show plainly, dials should 1 ft in diameter for every 10 ft of elevation and should set out flush with or se to the line of the building or tower." †

Dimensions of Some Large Clock-Faces. Colgate's Factory, Jersey ty, N. J. The diameter of the dial is 40 ft. The minute-hand is 20 ft long d 2 ft 11 in in extreme width, and the hour-hand is 15 ft long and 3 ft 10 in extreme width. The minute-hand weighs 640 lb and the hour-hand 500 lb. is is the largest clock in the world.

* For a description of the requirements of installation of tower-clocks, see page 154 "Churches and Chapels," by F. E. Kidder.

are 23 ft 4 in in diameter.

LIBRARY BOOK-STACKS

The Stack-Work in General. The stack-room of a library is usually c
off by fire-proof doors from the rest of the building. The customary prac
among architects is to make the stack-work a separate contract and have t
general contractor turn the stack-room over to the stack-contractor with fi
ished floors, walls and ceilings. The stacks, made entirely of incombusti
materials, are then built as an independent structure.

Book-Ranges. The book-ranges are usually double-faced and are pl
in parallel rows with aisles between. The minimum aisle-width is about 2
4 in. Radial ranges waste space and are costly. Single-faced ranges a
relatively more expensive than double-faced ranges.

Tiers. All stacks are divided in their height into tiers by deck-floors
order that all shelves may be easily reached. The regular tier-height is 7
or 7 ft 6 in.

Deck-Floors. Deck-floors are composed of slabs of ¾-in rough pl
glass or 1¼-in white marble, supported on steel framework. A long, narr
opening or deck-slit is left between the edge of each deck-floor and the face
each range to allow proper ventilation of the stack-tiers. The net thickn
from top of deck to bottom of steel framework is from 3¼ to 3¾ in for ordina
spans. The deck-floors are carried by the shelf-supports.

Vertical Communication. Continuous flights of stairs of simple desi
and construction are placed at central points. Books are moved up and do
by means of dumb-waiters operated by hand, for short runs, or by electr
power controlled by push-buttons.

Shelf-Supports. The shelf-supports are made in various ways, diffe
with each manufacturer. In the best construction they extend the full wi
of the shelves so as to hold up the shelves and books without the use of
projecting brackets. They are made of sufficient strength to carry the co
bined loads of books, deck-floors and superimposed stack-tiers. They sh

* Destroyed in the earthquake and fire.

ovide for a uniform shelf-adjustment at intervals of about 1 in. Compactness is important. Open-work shelf-supports promote proper lighting and ventilation.

Shelves. In each tier of regular height there are usually six rows of adjustable shelves and one row of fixed shelves. Shelves are generally 8 or 10 in wide and 3 ft long. Other sizes are supplied if necessary. The adjustable shelves are made of solid plates of sheet steel or of parallel bars with spaces between. The fixed shelves are placed about 2 in above each floor-level. They are made of solid plates of steel to form dust-stops, fire-stops and water-stops between the tiers.

Finish. The adjustable shelves are always completely finished with baked enamel before delivery. The fixed parts, also, of the stack-construction may be finished at the shop with baked enamel, or preferably with air-drying enamel, after erection at the building, so as to permit repair.

Lighting. Electric-light wires are carried in metal conduits supported by the steel framework of the deck-floors. Lights of 16 candle-power are spaced about 6 ft apart in range-aisles and 12 ft apart in main aisles.

Heating. Indirect radiation is best for books. The lower tiers, only, of a stack should be heated, to prevent the upper tiers from becoming too warm.

Ventilation. Large stacks are usually ventilated artificially to prevent the entry of dust and outside air through open windows. In the Library of Congress, in Washington, D.C., fresh, filtered and tempered air is forced in at the bottom tier, finds its way up through the stack by means of the deck-slits and is drawn out at the top tier.

Weights. The shelves and shelf-supports * weigh from 7 to 10 lb per cu ft of book-range. Books weigh about 20 or 25 lb per cu ft of book-range. The steel deck-floor framing weighs from 4 to 6 lb per sq ft of gross area of deck-floor. Marble floor-slabs, 1¼ in thick, weigh about 20 lb per sq ft, and ¾-in rough, plate-glass slabs, about 10 lb per sq ft of net area.

Book-Capacities. Book-capacities per linear foot of shelf may be figured on the following basis: law-books, 5 volumes; reference books, 6 volumes; scientific books, 7 volumes; general literature, from 8 to 10 volumes. The average in the Library of Congress is 8½ volumes per linear foot. An ordinary stack-tier, 7 shelves high with double-faced ranges 16 in deep (or 8-in shelves) and aisles 32 in wide, with a reasonable allowance made for cross-aisles, stairways, etc., will contain about 22 volumes per sq ft of gross area.

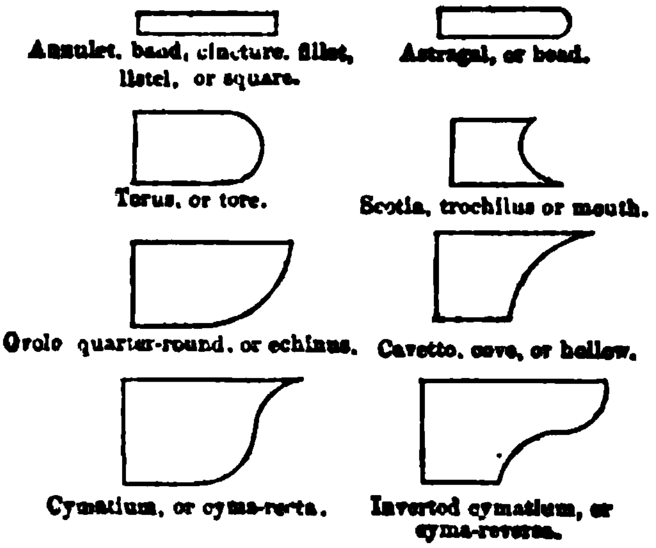
Cost. The cost in the United States of library-stacks of standard construction varies from 50 cts to $1 or more per linear foot of shelving. Economy is secured by following established standards while special designs increase the cost.

CLASSICAL MOLDINGS

Moldings are so called because they are of the same shape throughout their length as though the whole had been cast in the same mold or form. The regular moldings, as found in remains of classic architecture, are eight in number, as shown in the accompanying illustration, and are known by the following names: The last two are commonly called, also, OGEE MOLDINGS. Some of these names are derived thus: FILLET, from the French word FIL, a thread; ASTRAGAL, from ASTRAGALOS, a bone of the heel, or the curvature of the heel; BEAD, because the molding, when properly carved, resembles a string of beads; TORUS, or TORE,

* As made by Snead & Co., Jersey City, N. J.

the Greek for rope, which it resembles when on the base of a column; sco from SKOTIA, darkness, because of the strong shadow cast in its hollow, and wh is increased by the projection of the torus above it; OVOLO, from OVUM, an which this member resembles when carved, as in the Ionic capital; CAVE from CAVUS, hollow; CYMATIUM, fr KUMATON, a wave.



Characteristics of Moldin None of these moldings is peculiar t any one of the orders of architectu and although each has its appropri use, it is by no means confined to a certain position in an assemblage moldings. The use of the fillet an also of the astragal and torus, whi resemble ropes, is to bind the par The ovolo and cyma-reversa are stro at their upper extremities, and a therefore used to support projecti parts above them. The cyma-recta and cavetto, being weak at their upp extremities, are not used as supporters, but are placed uppermost to cover an shelter the upper parts. The scotia is introduced in the base of a column t separate the upper and lower torus, and to produce a pleasing variety an relief. The form of the bead and that of the torus are the same; the reas for giving distinct names to them is that the torus, in every order, is alwa considerably larger than the bead and is placed among the base-molding whereas the bead is never placed there, but on the capital or entablatu The torus, also, is seldom carved, whereas the bead is; and while the tor among the Greeks, was frequently elliptical in its form, the bead retains i circular shape. While the scotia is the reverse of the torus, the cavetto is th reverse of the ovolo, and the cyma-recta and cyma-reversa are combinatio of the ovolo and cavetto.

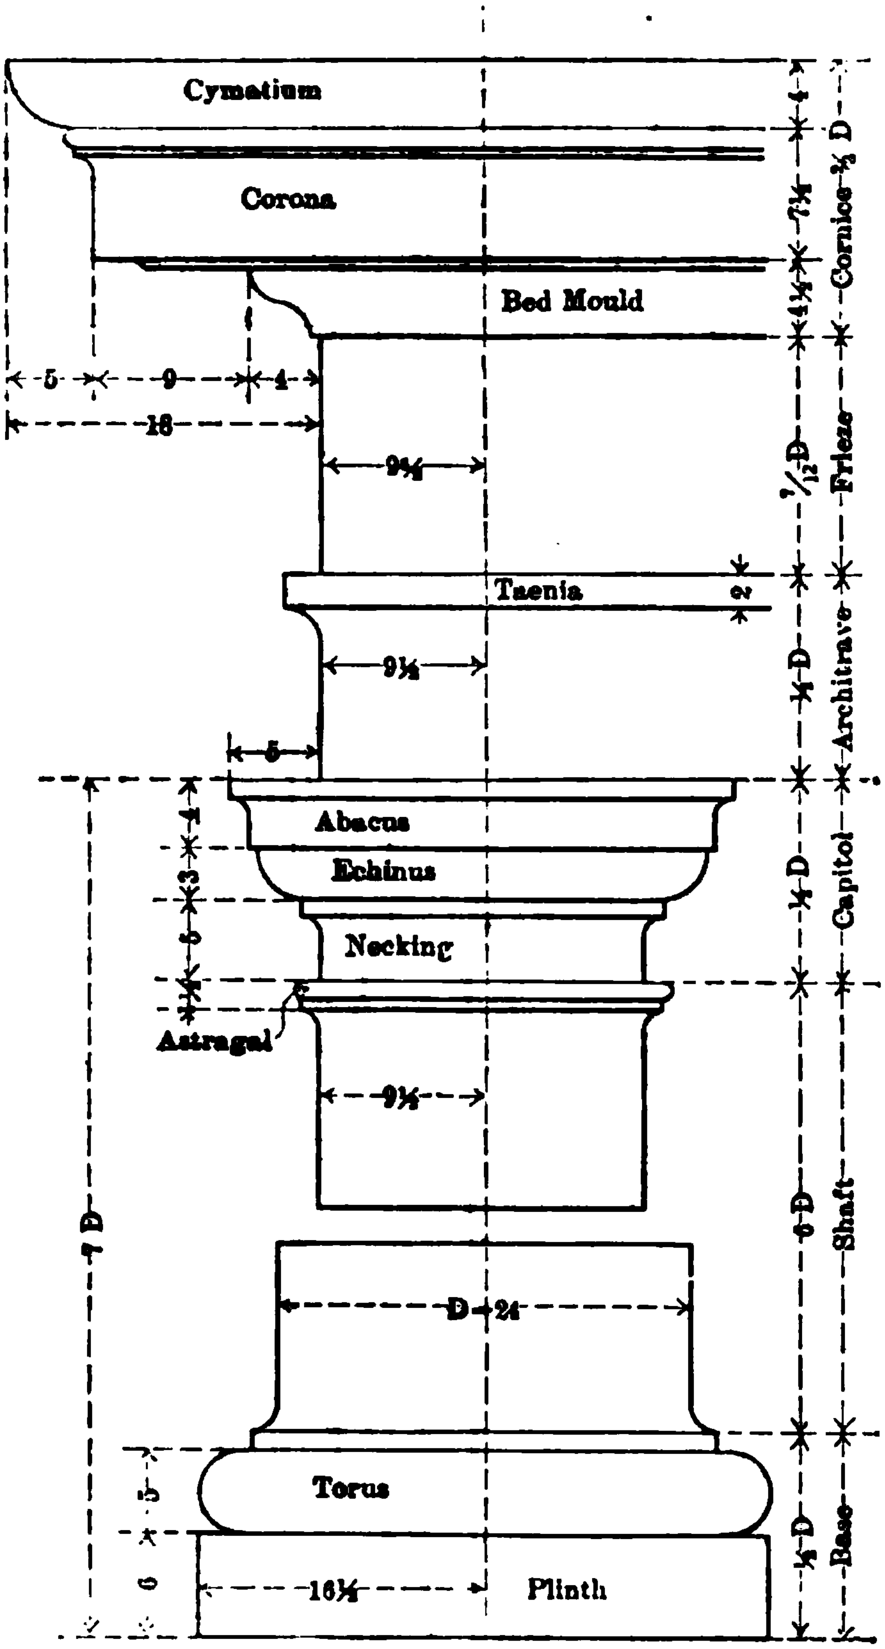
THE CLASSICAL ORDERS*

Origin of the Orders. "In the classical styles several varieties of colu and entablature are in use. These are called the ORDERS. Each order compris a COLUMN with a BASE, SHAFT and CAPITAL, with or without a PEDESTAL, with i BASE, DIE and CAP, and is crowned by an ENTABLATURE, consisting of ARCHITRAV FRIEZE and CORNICE. The entablature is generally about one-fourth as high a the column, and the pedestal one-third, more or less. Among the Greeks th forms used by the Doric race, which inhabited Greece itself and had colonies i Sicily and Italy, were much unlike those of the Ionic race, which inhabited th western coast of Asia Minor, and whose art was greatly influenced by that o Assyria and Persia. Besides the IONIC and DORIC styles, the Romans devise a third, which employed brackets, called MODILLIONS, in the cornice, and wa much more elaborate than either of them; this they called the CORINTHIA They used also a simple Doric called the TUSCAN, and a cross between th Corinthian and Ionic called the COMPOSITE. These are the FIVE ORDERS. Th

* The paragraphs in quotation-marks are taken from The American Vignola by Pr fessor W. R. Ware, by permission of the owners of the copyright, the International Tex book Company, Scranton, Pa., proprietors of the International Correspondence Schoo The engravings were made especially for this book, and correspond with the origi drawings prepared by Giacomo Barozzi da Vignola.

cient examples vary much among themselves and differ in different places, d in modern times still further varieties are found in Italy, Spain, France, ermany and England. The best known and most admired forms for the orders e those worked out by Giacomo Barozzi da Vignola in the sixteenth century om the study of ancient amples."

The Tuscan Order. The distinguishing aracteristic of the Tus- AN ORDER (Fig. 1) is mplicity. Any forms pedestal, column and tablature that show ut few moldings, and ose plain, are con- dered to be TUSCAN."



Dimensions are in 24ths of Diameter.

Fig. 1. The Tuscan Order

The Doric Order. The distinguishing aracteristics of the ORIC ORDER are fea- ires in the FRIEZE and the BED-MOLD above called TRIGLYPHS and UTULES, which are sup- osed to be derived from ie ends of beams and afters in a primitive ooden construction ith large beams. Un- er each triglyph, and eneath the TÆNIA which rowns the architrave, is little fillet called the EGULA. Under the egula are six long drops, alled GUTTÆ, which are ometimes conical, some- imes pyramidal. There re also either eighteen r thirty-six short cylin- rical guttæ under the ffit of each mutule. he guttæ are supposed o represent the heads of ooden pins, or treenails. wo different Doric cor- ices are in use, the MUTULARY with bracket and the DENTICULATED with dentils, he principal difference being in the BED-MOLD." The order shown in Fig. 2 as the denticulated cornice.

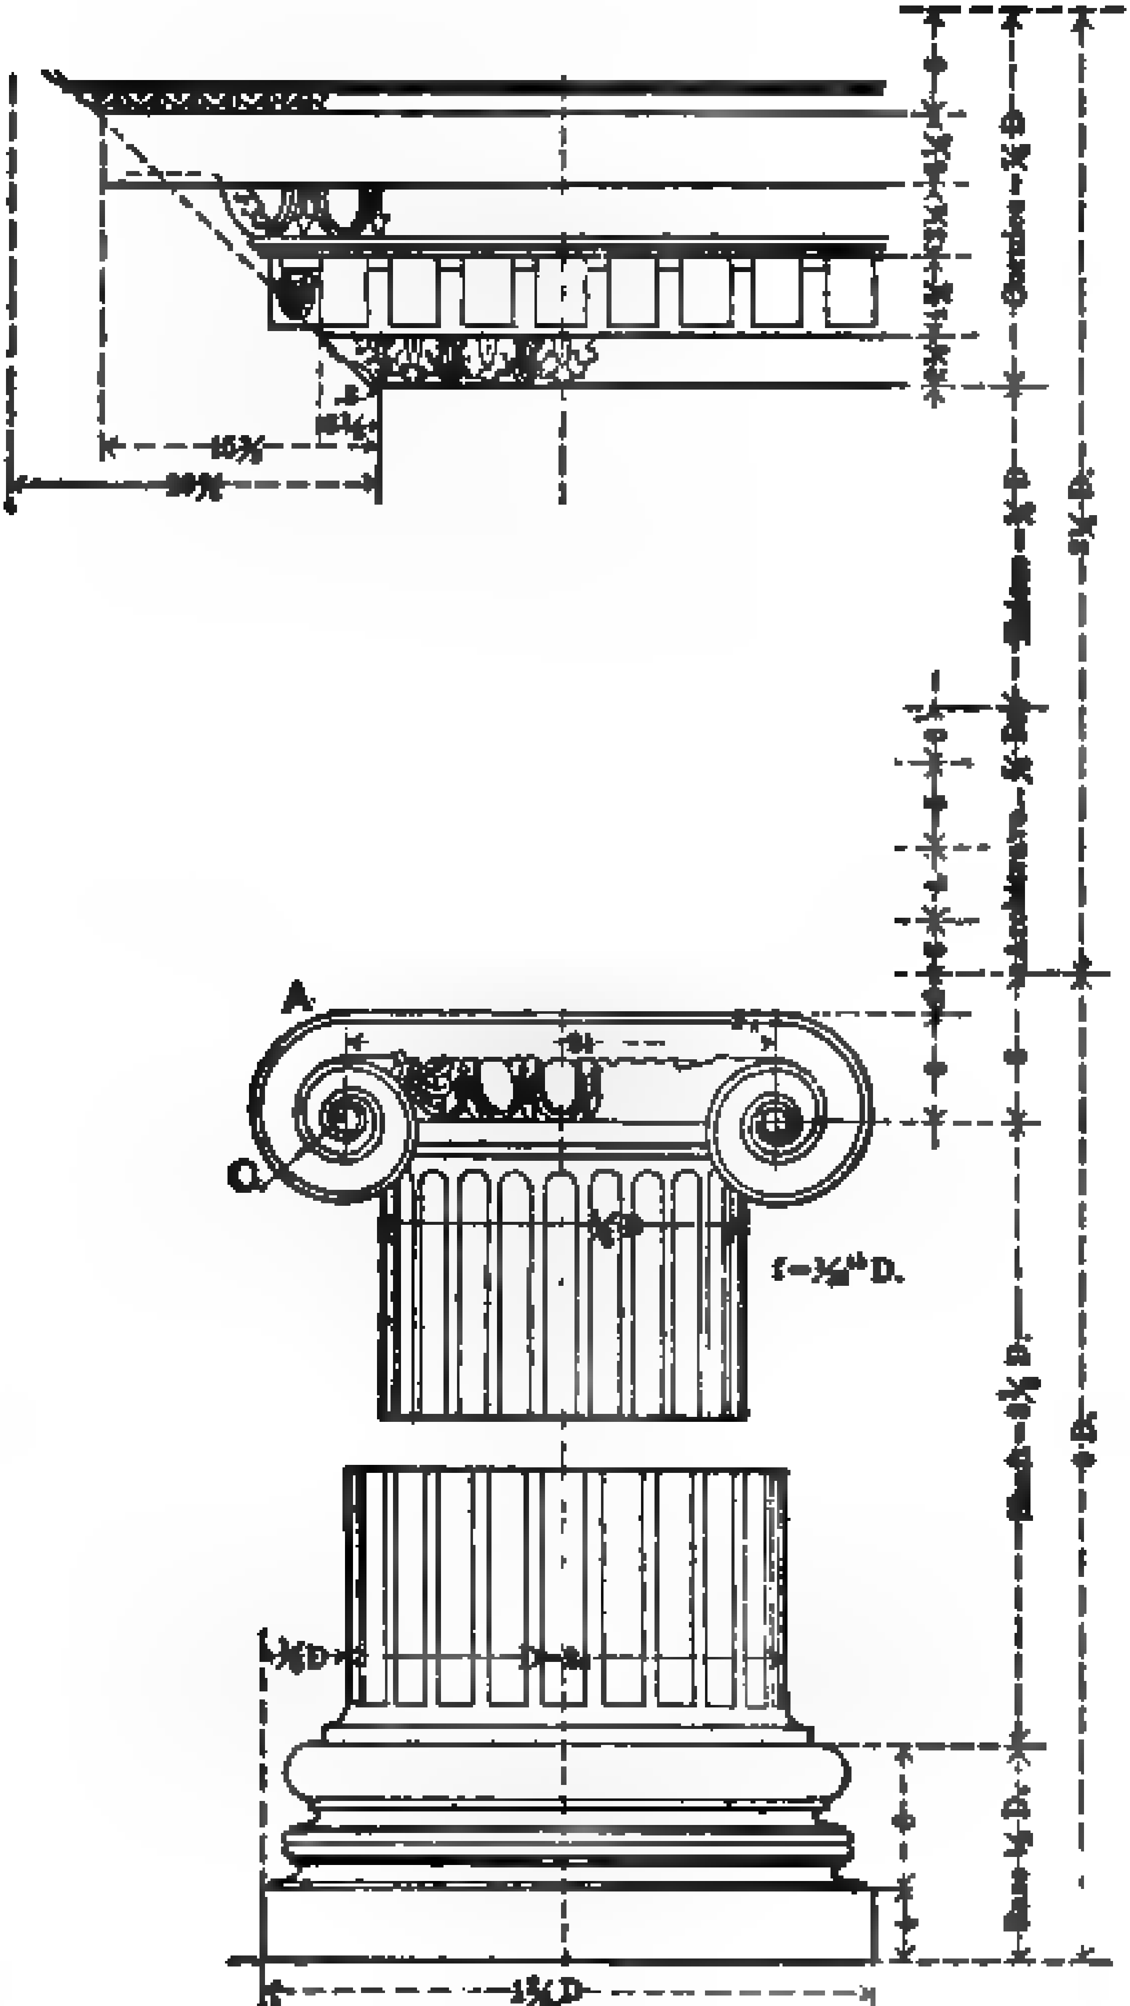
The Ionic Order. "The prototypes of the IONIC ORDER (Fig. 3) are to be ound in Persia, Assyria, and Asia Minor. It is characterized by BANDS in the rchitrave and DENTILS in the bed-mold, both of which are held to represent mall sticks laid together to form a beam or a roof. But the most conspicuous

and distinctive feature is the SCROLLS which decorate the CAPITAL of the colu
These have no structural significance, and are purely decorative forms deri
from Assyria and Egypt. Originally the Ionic order had no FRIEZE and n
ECHINUS in the capital. These were borrowed from the Doric order, and in

Dimensions are in 60ths of Diameter

Fig. 2. The Doric Order

like manner, the dentils and bands in the Doric were borrowed from the Ionic.
The Ionic frieze was introduced in order to afford a place for sculpture, and was
called by the Greeks the ZOOPHOROUS, or figure-bearer. The typical IONIC BASE
is considered to consist mainly of a SCOTIA, as in some Greek examples. It is
common, however, to use instead what is called the ATTIC BASE, consisting of



Dimensions are in 60ths of Diameter.

Fig. 3. The Ionic Order

SCOTIA and two FILLETS between two large TORUSES, mounted on a PLINTH, the whole half a diameter high. The plinth occupies the lower third, or one-sixth of a diameter. Vignola adopted for his Ionic order a modification of the Attic base, substituting for the single large scotia two small ones, separated by one or two beads and fillets, and omitting the lower torus." This is the base shown in Fig. 3. "The Ionic frieze is plain, except for the sculpture upon it. It sometimes has a curved outline, as if ready to be carved, and is then said to be PULVINATED, from pulvinar, a bolster, which it much resembles. The shaft of the column is ornamented with twenty-four FLUTINGS, semicircular in section, which are separated not by an ARRIS, but by a FILLET of about one-fourth their width. This makes the flutings only about two-thirds as wide as the Doric channels, or about one-ninth of a diameter, instead of one-sixth."

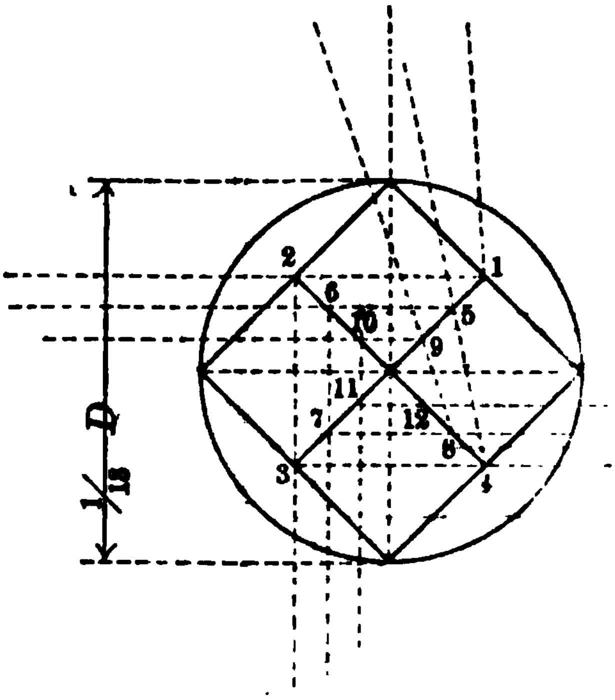


Fig. 4. The Ionic Volute

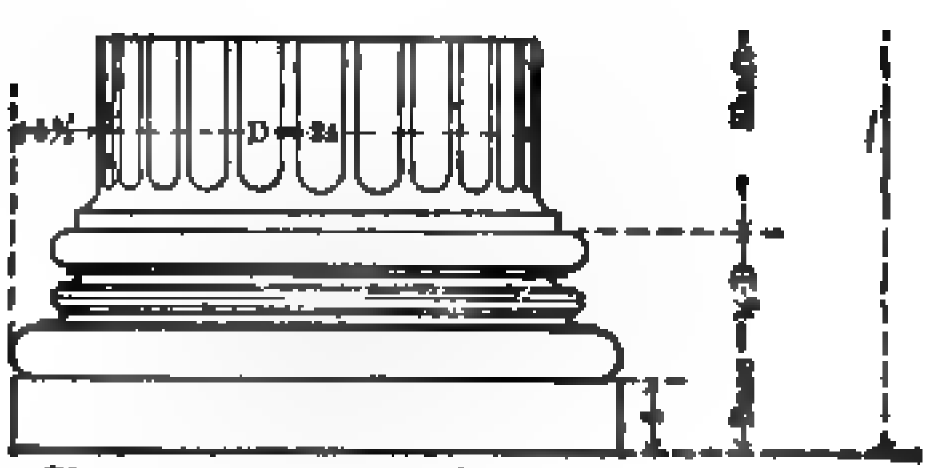
To Describe the Ionic Volute. There are several methods of doing this, the simplest being by means of centers found as shown by the diagram in Fig. 4. First locate the center of the EYE ½ *D* vertically below the point *A*, Fig. 3. Then describe a circle with a diameter equal to 1/18 *D*, to form the eye. Inside of this circle inscribe a square at 45 degrees to a horizontal; then draw the axes 1–3 and 2–4, and divide each of these into six equal parts. Then with the point 1 as a center, and a radius extending to *A*, Fig. 3, draw a quarter-circle to line 1–2 produced, with 2 as a center, continue the curve until it intersects 2–3 produced, and so on. The centers for the outer curve of the volute are at the points 1, 2, 3, 4, 5, 6, etc. For the centers for the inner curve, start with a point one-third the way from 1 to 5, then a point one-third the way from 2 to 6, and so on.

The Corinthian Order. "The three distinguishing characteristics of the CORINTHIAN ORDER (Fig. 5) are a tall, bell-shaped capital, a series of small brackets called MODILLIONS, which support the cornice instead of MUTULES, in addition to the DENTILS, and a general richness of detail which is enhanced by the use of the ACANTHUS LEAF in both capitals and modillions. Here, again, the ATTIC BASE is commonly used, but sometimes, especially in large columns, a base is used which resembles Vignola's IONIC BASE, except that it has two BEADS between the SCOTIAS instead of one, and also a lower TORUS. The SHAFT is fluted like the Ionic shaft, with twenty-four semicircular FLUTINGS, but they are sometimes filled with a convex molding or CABLE to a third of their height. Almost all the buildings erected by the Romans employ the Corinthian order."

The Composite Order. "The COMPOSITE ORDER is a heavier Corinthian, just as the Tuscan is a simplified Doric. The chief proportions are the same as in the Corinthian order, but the details are fewer and larger. It owes its name to the CAPITAL, in which the two lower rows of leaves and the CAULICOLI are the same as in the Corinthian. But the caulicoli carry only a stunted LEAF-BELL, and the upper row of leaves and the sixteen VOLUTES are replaced by the large ECHINUS, SCROLLS and ASTRAGAL of a complete Ionic capital. Vignola's composite entablature differs from his Ionic chiefly in the shape and size of the



Dimensions are in 24ths of Diameter

THE CORINTHIAN ORDER

DENTILS. They are larger, and are more nearly square in elevation, bein fifth of a diameter high and one-sixth wide, the INTERDENTIL being one-t

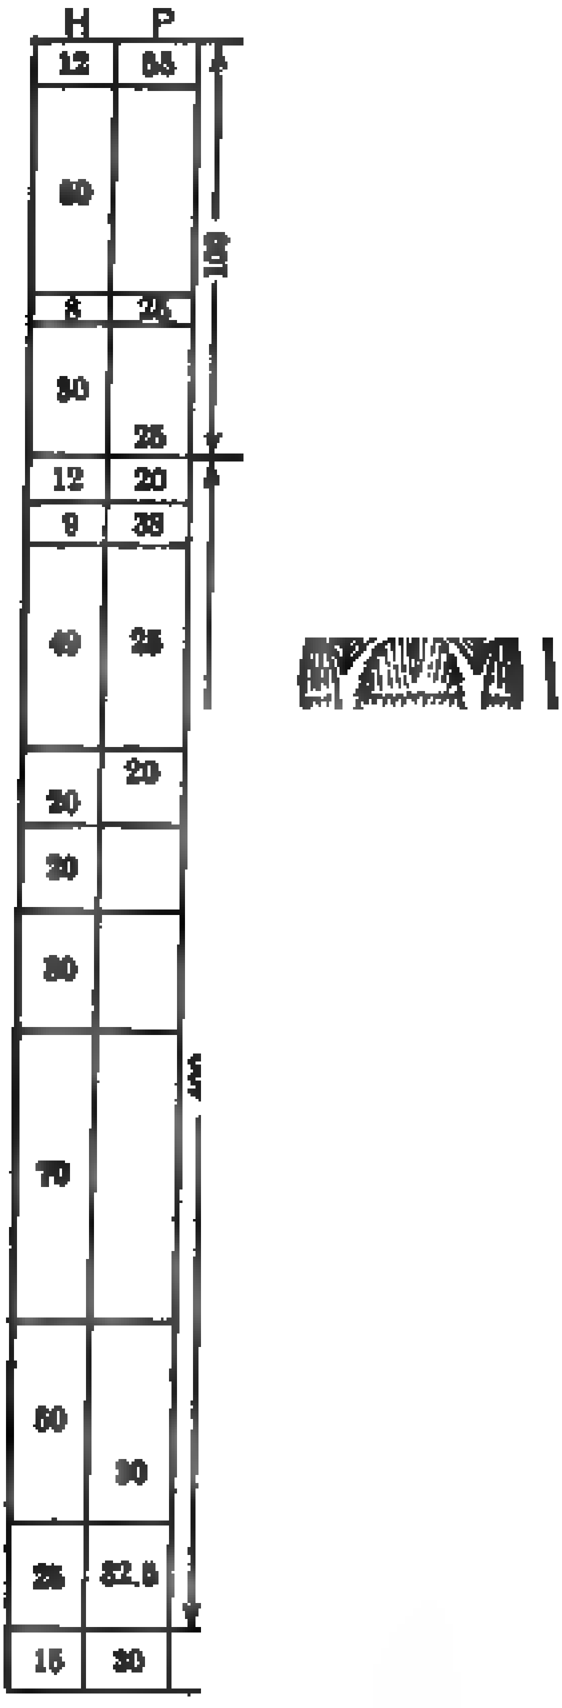

Fig. 6. An Egyptian Order. Diameter Divided into Sixty Parts

and they are set one-ha a diameter apart, on ce The composite capital is ployed in the Arch of Tit Rome, and elsewhere, wi Corinthian entablature, and BLOCK CORNICE occurs in th called FRONTISPIECE of N as well as in the temple Athens, in connection wi Corinthian capital."

Egyptian Style.* The a tecture of the ancient Egypt is characterized by boldnes outline, solidity, and grand The principal features of EGYPTIAN STYLE of architect are: uniformity of plan, n deviating from right lines angles; thick walls, having outer surface slightly deviat inwardly from the perpendic the whole building low; roofs composed of stones reaching one piece from pier to p these being supported by e mous columns, very stout proportion to their height shaft sometimes polygonal, h ing no base, but with a g variety of handsome capit the foliage of these being of palm, lotus and other lea ENTABLATURES having sim an ARCHITRAVE, crowned wit huge CAVETTO ornamented w sculpture; and the INTERCOLU NIATION very narrow, usu $1\frac{1}{2}$ diameters and seldom ceeding $2\frac{1}{2}$. A great dissi larity exists in the proporti forms and general features of Egyptian columns. For practical use the colu shown in Fig. 6 may be taken as a standard of the Egyptian style.

LIGHTNING-CONDUCTORS

Rules for the Erection of Lightning-Conductors. The following r for the erection of lightning-conductors were issued in 1882 by the Departme Explosives of the English Home Office to the occupiers of all factories and ma

* From The American House Carpenter, by R. G. Hatfield.

for explosives, and to those local and police authorities upon whom de-
es the inspection of stores of explosives:

) **Material of Rod.** Copper, weighing not less than 6 oz per ft run, the rical conductivity of which is not less than 90% of that of pure copper, er in the form of rod, tape, or rope of stout wires, no individual wire being than No. 12, Birmingham Wire-Gauge (0.109 in) the English standard -gauge. Iron may be used, but should not weigh less than 2½ lb per foot n.

) **Joints.** Every joint, besides being well cleaned and screwed, scarfed, iveted, should be thoroughly soldered.

) **Form of Points.** The point of the upper terminal * of the conductor ld not have an angle sharper than 90°. A foot below the extreme point a er ring should be screwed and soldered on to the upper terminal, in which should be fixed three or four sharp copper points, each about 6 in long. desirable that these points should be so platinized, gilded, or nickel-plated resist oxidation.

) **Number and Height of Upper Terminals.** The number of conductors or er terminals required will depend upon the size of the building, the material hich it is constructed, and the comparative height above ground of the ral parts. No general rule can be given for this, except that it may be med that the space protected by the conductor is, as a rule, a cone, the is of whose base is equal to the height of the conductor from the ground.

) **Curvature.** The rod should not be bent abruptly around sharp corners. o case should the length of a curve be more than half as long again as its d. A hole should be drilled in string-courses or other projecting masonry, n possible, to allow the rod to pass freely through it.

) **Insulators.** The conductor should not be kept from the building by or other insulators, but attached to it by fastenings of the same metal as of the conductor itself.

) **Fixing.** Conductors should preferentially be taken down the side of building which is most exposed to rain. They should be held firmly, but holdfasts should not be driven in so tightly as to pinch the conductor or ent contraction and expansion due to change of temperature.

) **Other Metalwork.** All metallic spouts, gutters, iron doors, and other es of metal about the building should be electrically connected with the uctor.

Earth-Connection. It is most desirable that, whenever possible, the r extremity of the conductor should be buried in permanently damp soil. ce, proximity to rain-water pipes and to drains or other water is desirable. a very good plan to bifurcate the conductor close below the surface of the nd, and to adopt two of the following methods for securing the escape of ightning into the earth: (*a*) A strip of copper tape may be led from the om of the rod to a gas or water-main (not merely to a leaden pipe), if such near enough, and be soldered to it; (*b*) a tape may be soldered to a sheet pper, 3 by 3 ft by 1/16 in thick, buried in permanently wet earth and sur- ded by cinders or coke; (*c*) many yards of copper tape may be laid in a h filled with coke, having not less than 18 sq ft of copper exposed.

) **Protection from Theft, etc.** In places where there is any likelihood of copper being stolen or injured, it should be protected by being enclosed

* The upper terminal is that portion of the conductor which is between the top of the e and the point of the conductor.

in an iron gas-pipe, reaching 10 ft (if there is room) above ground and a distance into the ground.

(11) **Painting.** Iron conductors, galvanized or not, should be painted. I optional with copper ones.

(12) **Inspection.** When the conductor is finally fixed it should in all c be examined and tested by a qualified person, and this should be done i case of new buildings after all work on them is finished. Periodical exami tion and testing, should opportunities offer, are also very desirable, espe when iron earth-connections are employed.

Lightning-Protection for High Chimneys. The following is a desc tion of the system of lightning-protection for the radial-brick chimney-st 350 ft in height, for the plant of the St. Joseph Lead Company, Herculan Mo.

Conductor. The conductor used is of commercially pure copper, No. Brown & Sharpe gauge, in the form of a cable, consisting of twenty-e wires, seven strands, four wires to the strand, and 5/8 in in diameter, 230 circular mils. The vertical conductors are of continuous lengths from the of the chimney to and into the ground. A circuit-conductor is placed below the top of the chimney and connected to each down-conductor by a t two-way splice.

Points. The air-terminals are eight in number equally spaced around top of the chimney, and consist of solid, copper bars 1 in in diam and 10 f length, the upper 12 in tapering to a point and covered with a 12-in thimbl genuine platinum. Air-terminals extend 5 ft above the top of the stack; the lower end of each copper bar is set in a heavy copper T coupler, which c nects the same into the circuit-conductor. Each rod is held in place by he anchor-fasteners, bolted from the inside of the stack. These anchors are cased in copper tubes set in the solid masonry.

Grounding. At a point below the ground-level and at the chimney-l the conductor is carried in a downward course from the chimney, in a tre bedded in charcoal, to a point 5 ft outside the foundation-line. An additi conductor is spliced into the main cable at this point, forming a Y w branches terminating 15 ft apart. Two well-holes are bored to a depth of proximately 20 ft into permanent moisture. The end of each Y conducto electrically soldered into perforated, copper reservoirs 4½ in in diam and 1 in length, and filled with pea-size charcoal. The effect of the reservoir is give the required amount of surface-contact with the earth and to insure p manent moisture through the charcoal by capillary attraction. Each m conductor is thus grounded in two places instead of in one place.

Lead Covering. To preserve the conductor system against decomposi in ozone, in which sulphuric or other acid gases may exist, all of the condu system at the top, and to a point 75 ft below the top of the chimney is cove with lead 1/8 in in thickness. Exception is made to the platinum-covered t top of each rod, which requires no lead covering. Where splices are made anchor-fasteners set, the whole is covered with lead sleeves or hoods thorou wiped and hermetically sealed. Connections of point-bar T's etc., are soldered, lead-covered and sealed. Practical experience seems to show t all lightning-conductor systems on chimneys should be lead-covered hermetically sealed to a point, approximately 25 ft downward from the top protect the copper against decomposition, not necessarily as thick as on chimney, but, say, 1/16 in, the thickness being determined by the size and s

of the stack. It has been found that in from three to five years there is a decided honeycombing of the copper, through the action of the sulphuric and other acid gases. It has often been necessary to replace points, sections of cable, etc., entirely eaten away from this cause.

INTERPHONES. AUTOMATIC TELEPHONES FOR INTERCOMMUNICATING SERVICE

Description. The interphone system is an application of the telephone for interior use. It is an automatic, intercommunicating system, requiring neither switchboard nor operator, and being self-contained within the walls of the establishment for whose benefit it has been installed.

Advantages. In brief, the advantages of such a system are these: (1) the mere pressing of a button gives a person telephone-connection with any desired party, without the loss of time involved in first calling up a third party; (2) recourse to directory or information bureau is made unnecessary through the use of labels, properly inscribed, on the face of the instrument; (3) no maintenance-expense is involved, and the system, consequently, is as inexpensive to operate as an electric door-bell; (4) the wiring-arrangement is such that the system may be provided for when the original plans for a new building are being drawn up, and in this respect it does not differ much from a system of electric lights or plumbing.

The Use of Interphones in residences, schools, hospitals, factories, mills, offices, stores and clubs is constantly increasing. The same general features apply to all of these types of installations, and in practically every case it is the simplicity of the system that especially recommends it for service. The interphone usually fits in where formerly call-bells, speaking-tubes, messenger service and other inadequate methods were the rule. The interphone field of service is in the establishment whose needs call for from four to thirty-two telephone-stations. When there are more than thirty-two the installation of a private telephone-exchange, with a switchboard, is better practice.

Types of Interphones. There are several types of interphones for varying degrees of service.

(1) The most familiar instrument is a wall-interphone, of the NON-FLUSH TYPE. The telephone is of metal, with connecting buttons, labels, bells, mouthpiece, hook and receiver, all mounted on its face. This instrument is to be attached directly to the wall.

(2) The FLUSH TYPE resembles the first-mentioned type in every particular but the one implied in its title. The instrument is mounted into the wall, with its face flush with the rest of the wall-surface. These two instruments are most popular for installation in club-hallways, in stores and factories, in residences, and in all places where wall-telephones would ordinarily be used. Busy offices and stores often employ variations of types (1) and (2) and use a DESK-SET, a separate instrument taking care of the connecting buttons and labels, or a HAND-SET.

(3) The DESK-STAND telephone is of the type often used for local and long-distance service. Connected with it is a metal box containing the rows of buttons and labels, each label being opposite the button through which is secured connection with the corresponding station. The telephone in this case stands on the desk, and the key-box is conveniently close at hand, either on the desk or on the wall.

(4) Some prefer for this service the HAND-SET, with the receiver and transmitter in one piece. This is a convenient, compact instrument, well fitted for use in an office.

(5) From two to six instruments of still another type make up a PARTY-LINE INTERPHONE SYSTEM. Here there are no connecting buttons, the principle involved being the same as that of the elementary, farmers' line. This makes a convenient private-line system for a small residence, and is appropriate for a house-to-garage circuit.

Variations from Standard Types. There are systems with variations from the standard types. Many schools are using a combination of interphones of type (1) or (2) with (5). In the principal's office is an instrument of type (1) or (2) with a connecting button for each outside station, while the classroom-telephones are all of type (5). With this system the principal can at any time call up any teacher; but a teacher can call up another classroom only through the medium of this MASTER-STATION, which acts as a sort of exchange. The advantages of this arrangement for a school are obvious. In a hospital the instruments are usually placed outside of the more important operating-rooms and wards and in the offices and reception-rooms.

Wiring and Batteries. All wiring is enclosed in cables. Energy is obtained from dry cells. The only maintenance-expense connected with an interphone system is the occasional renewal of these batteries.

VACUUM-CLEANING

General Description. Vacuum-cleaners are appliances which have come into use during recent years and which are for the purpose of removing dirt and dust from rooms of buildings, cars, steamships, etc., or from furniture, carpets, curtains, or other interior fittings. The dust and dirt are removed by suction and the apparatus consists of an air-pump which is arranged to draw the air and the dirt or dust contained in it through pipe and nozzle. The nozzle is drawn or passed over the surfaces which are to be cleaned. Screens of muslin or other appropriate cloth are used to separate by filtration the dust and dirt which are borne along with the stream of air; and in some types of apparatus this process is assisted by what are called baffle-plates which are added to make the heavier particles of dust drop by their own weight to the lower part of the receptacle placed to receive them. About the year 1890 compressed air was used for the first time in railroad-cars for purposes of cleaning and dust-removal. There were serious objections to this method of cleaning, however, as it was found that the jets of compressed air blew out the dust and dirt in such a way that it was difficult to arrange for their collection and retention; the principle of suction was consequently introduced to overcome these difficulties.

Types of Vacuum-Cleaners. The machines belonging to the earliest types usually consist of a pump, the motor-power of which is either a gas-engine or an electric motor, the machines being portable. They can be moved about from one building to another as occasion demands. Cleaners of the next type introduced involve an installation in the basement or lower part of a building and a fixed and permanent position. From the central plant pipes are run to various rooms and apartments and are fitted in such rooms or apartments or in adjacent halls or corridors, with valves to which are attached the hose with the cleaning appliances at the end. In some cases this vacuum-arrangement is combined with another for washing floors, the secondary system including a second set of pipes from a tank filled with soap and water. Compressed air is employed to spray the latter over the floor, and both dirt and water are finally removed

through pipes to the street-sewers. A portable tank is used for the soap and water. Vacuum-cleaners of a third type consist of small machines which take the place of the brooms and dusters or are used in connection with them. They are now very generally used and may be driven by an electric motor, by foot, or by hand. These last-mentioned, smaller, portable cleaners are used for many other purposes than the ordinary cleaning of rooms and furniture.

Details and Specifications for Vacuum-Cleaning Installations. Complete plans and specifications for the installation of a vacuum-cleaning plant for a building may be obtained from any of the numerous manufacturers making such apparatus and taking contracts to put it in place. There are several types of machines and systems of installation and detailed descriptions would exceed the limits of space in this handbook.

WATERPROOFING FOR FOUNDATIONS *

The Waterproofing of Substructure Work is, comparatively speaking, a modern branch of engineering. It is only within recent years that it has become necessary to construct deep basements for buildings. In the past, the more important structures, such as cathedrals, capitols, state-buildings and the like, were usually built upon high ground, and water was prevented from entering the basements of such buildings by means of drainage. Waterproofing, as we now know it, was generally unnecessary. With the advent of the so-called sky-scrapers, however, requiring large mechanical plants, deep basements became an actual necessity, and as these basements are usually carried below ground-water level, and in many instances below tide-level, the question became one of utmost importance. Like almost every detail of a modern building, waterproofing is a specialty. Each building presents its own problems, and the safest plan is to leave the solution of these problems to some one expert in the knowledge of waterproofing who has made it a special study and knows how best to overcome the existing difficulties. It may be laid down as an invariable rule that, where conditions are at all serious, the owner or the general contractor will save money in the long run if he employs the services of an expert waterproofer to place his waterproofing-seal, regardless of the method he wishes to use.

Pressure-Resistance Versus Waterproofing. In waterproofing large basements where actual pressure exists, it is a question for the engineer to decide whether it is more economical to attempt to secure an absolute PRESSURE-JOB or a WATER-PROOF JOB in connection with a drainage system. As a general rule, it may be stated that where a building is generating its own power, it is more economical to use a drainage system with an open sump than to construct a pressure-cellar, the cost of pumping being much less than the interest charges on the cost of a floor-slab sufficiently strong to withstand the pressure.

Waterproofing Concrete Foundations. The three following subdivisions of this subject, discussing the causes of permeability of concrete, the addition of substances to render it more water-proof, and the treatment of its surfaces to make it less permeable, embody the conclusions of Committee D–8 of the American Society for Testing Materials.† This committee, since its organization in 1905 has, through laboratory-tests and experiments, together with examinations of work during construction and after completion, as well as the study of literature on the subject, sought to secure sufficient information to enable it to for-

* For foundations in general, see Chapter II.

† This article, to the middle of page 1713, is the substance of a Report submitted to the American Society for Testing Materials at its meeting, June 24–28, 1913. This Society has (1920) no Standard Specifications for Waterproofing, but published in 1918 our Tentative Specifications on this subject.

mulate definite methods for securing water-proof concrete structures. The work of the committee was complicated by reason of the facts that there seemed to be so little concordance between results of tests obtained under laboratory-conditions and in the field and that it was necessary to extend its investigations over a period of years in order to determine the permanency of the action noted. The committee reported that while it had not been able to arrive at sufficiently definite conclusions to enable it to formulate specifications for the making of concrete structures water-proof or for materials to be used in such work, it had reached certain general conclusions which might be of assistance to the constructor in securing the desired result of impermeable concrete. Early in the investigation, the work was found to subdivide naturally into three branches, and the conclusions reached will be grouped in order under these subdivisions, which are:

(1) The determination of causes of the permeability of concrete as usually made from mixtures of Portland cement, sand and stone, or other coarse aggregate, in proportions of from 1 of cement, 2 of sand and 4 of stone, to 1 of cement, 3 of sand and 6 of stone, and the best methods of avoiding these causes.

(2) The rendering of concrete more water-proof by adding to ordinary mixtures of cement, sand and stone, other substances which, either by their void-filling or repellent action, would tend to make the concrete less permeable.

(3) The treatment of exposed surfaces after the concrete or mortar has been put in place and hardened more or less, either by penetrative, void-filling or repellent liquids, making the concrete itself less permeable; or by extraneous protective coatings, preventing water from having access to the concrete.

Considering these several subdivisions separately and in the order named, the committee arrives at the following conclusions:

(1) **Causes of Permeability of Concrete.** In the laboratory and under test-conditions where properly graded and sized coarse and fine aggregates are used, in mixtures ranging from 1 of cement, 2 of sand and 4 of stone, to 1 of cement, 3 of sand and 6 of stone, impermeable concrete can invariably be produced. Even with sand of poor granulometric composition, with mixtures as rich as 1 of cement, 2 of sand and 4 of stone, permeable concrete is seldom, if ever, found and is a rare occurrence with mixtures of 1 of cement, 3 of sand and 6 of stone. But the fact remains, nevertheless, that the reverse often obtains in actual construction, permeable concretes being encountered even with mixtures of 1 of cement, 2 of sand and 4 of stone and are of frequent occurrence where the quantity of the aggregate is increased. This the committee attributes to:

(a) Defective workmanship, resulting from improper proportioning, lack of thorough mixing, separation of the coarse aggregate from the fine aggregate and cement in transporting and placing the mixed concrete, lack of density through insufficient tamping or spading, improper bonding of work-joints, etc.

(b) The use of imperfectly sized and graded aggregates.

(c) The use of excessive water, causing shrinkage-cracks and formation of laitance-seams.

(d) The lack of proper provision to take care of expansion and contraction, causing subsequent cracking.

Theoretically, none of these conditions should prevail in properly designed and supervised work, and they are avoided in the laboratory and in the field, under test-conditions, where speed of construction and cost are negligible items, instead of being governing features as they must be in actual construction. Properly graded sands and coarse aggregates are rarely, if ever, found in nature in sufficient quantities to be available for large construction, and the effect of poorly graded

aggregates in producing permeable concrete is aggravated by poor and inefficient field-work. Even if the added expense of screening and remixing the aggregates could be afforded, so as to secure proper granulometric composition to give the density required to make untreated concretes impermeable, it is seemingly often a commercial impossibility on large construction to obtain workmanship even approximating that found in laboratory-work.

(2) **Addition of Foreign Substances to Cement Before or During Mixture.** The committee finds that in consequence of the conditions outlined above, substances calculated to make the concrete more impermeable, either incorporated in the cement or added to the concrete during mixing, are often used. This has resulted in the development and placing on the market of numerous patented or proprietary waterproofing-compounds, the composition of which is more or less of a trade-secret. While it has been impossible for the committee to test all of the special waterproofing-compounds being placed on the market, it has investigated a sufficient number of these, as well as the use of certain very finely divided, naturally occurring or readily obtainable commercial mineral products, such as finely ground sand, colloidal clays, hydrated lime, etc., to form a general idea of the value of the different types. The committee finds:

(a) That the majority of patented and proprietary integral compounds tested have little or no immediate or permanent effect on the permeability of concrete and that some of these even have an injurious effect on the strength of mortar and concrete in which they are incorporated.

(b) That the permanent effect of such integral waterproofing-additions, if dependent on the action of organic compounds, is very doubtful.

(c) That in view of their possible effect, not only upon the early strength, but also upon the durability of concrete after considerable periods, no integral waterproofing-material should be used unless it has been subjected to long-time practical tests under proper observation to demonstrate its value, and unless its ingredients and the proportion in which they are present are known.

(d) That in general, more desirable results are obtainable from inert compounds acting mechanically, than from active chemical compounds whose efficiency depends on change of form through chemical action after addition to the concrete.

(e) That void-filling substances are more to be relied upon than those whose value depends on repellent action.

(f) That, assuming average quality in sizing of the aggregates and reasonably good workmanship in the mixing and placing of the concretes, the addition of from 10 to 20% of very finely divided void-filling mineral substances may be expected to result in the production of concrete which, under ordinary conditions of exposure, will be found impermeable, provided the work-joints are properly bonded, and cracks do not develop on drying, or through change in volume due to atmospheric changes, or by settlement.

(3) **External Treatment.** While external treatment of concrete would not be necessary if the concrete itself, either naturally or by the addition of waterproofing-material, was impermeable to water, it has been found in practice that in large construction, no matter how carefully the concrete itself has been made, cracks are apt to develop, due to shrinkage in drying out, expansion and contraction under change of temperature and moisture-content, and through settlement. It is, therefore, often advisable in important construction to anticipate and provide for the possible occurrence of such cracks by external treatment with a protective coating. Such coating must be sufficiently elastic and cohesive to prevent the cracks extending through the coating itself. The application of merely penetrative void-filling liquid washes will not prevent the passage of

water due to cracking of the concrete. The committee has, therefore, considered surface-treatment under two heads:

(a) Penetrative void-filling liquid washes.

(b) Protective coatings, including all surface-applications intended to prevent water coming in contact with the concrete.

Penetrative Washes. While some penetrative washes may be efficient in rendering concrete water-proof for limited periods, their efficiency may decrease with time and it may be necessary to repeat such treatment. Some of these washes may be objectionable, due to discoloring the surface to which they are applied. The committee, therefore, believes that the first effort should be made to secure a concrete that is impermeable in itself and that penetrative void-filling washes should only be resorted to as a corrective measure.

Protective Coatings. While protective extraneous bituminous or asphaltic coatings are unnecessary, so far as the major portion of the surface of the concrete is concerned, provided the concrete, either in itself or through the addition of integral compounds, is made impermeable, they are valuable as a protection where cracks develop in a structure. It is therefore recommended that a combination of inert void-filling substances and extraneous waterproofing be adopted in especially difficult or important work.

Bituminous or Asphaltic Coatings. Considering the use of bituminous or asphaltic coatings, the committee finds:

(a) That such protective coatings are often subject to more or less deterioration with time, and may be attacked by injurious vapors or deleterious substances in solution in the water coming in contact with them.

(b) That the most effective method for applying such protection is either the setting of a course of impervious brick dipped in bituminous material into a solid bed of bituminous material, or the application of a sufficient number of layers of satisfactory membranous material cemented together with hot bitumen.

(c) That their durability and efficiency are very largely dependent on the care with which they are applied. Such care refers particularly to proper cleaning and preparation of the concrete to insure as dry a surface as possible before application of the protective covering, the lapping of all joints of the membranous layers, and their thorough coating with the protective material. The use of this method of protection is further desirable because proper bituminous coverings offer resistance to stray electrical currents, the possible attack from which is referred to in succeeding paragraphs.

Rich Mixtures. So far, the committee has considered only concretes of the usual proportions, namely, those ranging from 1 of cement, 2 of sand and 4 of stone, to 1 of cement, 3 of sand and 6 of stone. It has been suggested that impermeable concretes could be assured by using mixtures considerably richer in cement. While such practice would probably result in an immediate impermeable concrete, it is believed by many that the advantage is only temporary, as richer concretes are more subject to check-cracking and are less constant in volume under changes of conditions of temperature, moisture, etc. Therefore, the use of more cement in mass-concrete would cause increased cracking, unless some means of controlling the expansion and contraction is discovered. With reinforced concretes the objection is not so great, as the tendency to cracking is more or less counteracted by the reinforcement.

Fine Flour Mixtures. It has also been suggested that the presence in the cement of a larger percentage of very fine flour might result in the production of a denser and more impermeable concrete, through the formation of a larger amount of colloidal gels. Neither of these suggestions has been especially investigated by the committee. Both appeal to the committee, however, for the

reason that they substitute active cementitious substances for the largely inactive void-filling materials previously recommended, thus increasing the strength of the concrete.

Character of Workmanship. In conclusion, the committee would point out that no addition of waterproofing-compounds or substances can be relied upon to completely counteract the effect of bad workmanship, and that the production of impermeable concrete can only be hoped for where there is determined insistence on good workmanship.

Saline Waters. Electrical Action. The production of impermeable concrete has assumed greater importance since the appointment of this committee, owing to the well-known injurious action of saline or alkaline waters and to the suggested possible effect of the moisture in concrete occasioning or aggravating electrical action from stray currents. Originally, the question of waterproofing involved mainly the physical troubles resulting from water passing through concrete without any special consideration of its effect on its durability, other than a gradual leaching out of the cement. Recent developments suggest the possibility that, owing to the increased conductivity of damp concrete to electrical currents, such currents, if present, may so affect damp concrete as to seriously lessen its integrity; and this possibility further emphasizes the importance of the recommendation that no waterproofing-compound of unknown chemical composition be added to concrete, as recent tests seem to show that the action of electrical currents is aggravated by the presence of certain solutions.

Waterproofing by External Linings of Brick, Tar, or Asphalt, and Felt. The oldest method of waterproofing is the one involving the use of a tar-and-felt or asphalt-and-felt seal (Fig. 1). This consists of building first a supporting wall and a supporting concrete slab to hold the seal. On the floors, this slab is usually composed of concrete, 4 in thick. The walls are generally of brick from 4 to 8 in thick, but occasionally 4-in terra-cotta tiles are used. Upon this base a swabbing of tar or asphalt is placed and before this has become cold or set, one thickness of paper, saturated with coal-tar, is laid. This paper receives a swabbing of coal-tar and asphalt and another layer of paper is placed, the operation being continued until there are three or more layers of paper with four or more swabbings of the tar or asphalt. For damp-proof work, three layers of paper with four swabbings of tar are usually sufficient. For waterproofing-work not less than five and usually six layers of paper with from six to seven swabbings of tar are used. The main walls of the structure are then built against the wall-waterproofing, and after these are in place, the main concrete basement-floor is laid immediately on top of the floor-seal, the idea being to form a continuous water-proof seal enveloping the entire basement below grade. The difficulties of this system consist chiefly in securing perfect laps at all points in the work, and unless extreme care is used and unless there is perfect coöperation between the waterproofer and the mason-contractor, there is apt to be a break somewhere in the seal, usually where the wall-waterproofing is supposed to be joined to the floor-work. The disadvantages of this system are due to the fact that the seal is not permanent in all soils as the subsurface water frequently contains acids which destroy the seal. Then again, the seal may be easily punctured by the mason-contractor in building his wall against it or in laying the concrete floor upon the flat work. The chief disadvantage, however, is that the waterproofing-seal is invariably buried behind a mass of masonry, either brick or concrete, which means that should there be a leak, due to either carelessness or accident, through the waterproofing-seal, it is frequently impossible to stop it. It not infrequently happens that when a leak has developed in tar-and-felt work, the actual presence of the water does not show opposite the leak,

but following some line of least resistance, appears from 50 to 100 ft, or more away from where the actual damage causing the leak occurs. In actual waterproofing work it is seldom attempted to secure a bottle-tight job with tar and felt. Instead, some system of drainage is installed beneath the water-proof seal which is on the floors of the building, and the water is conducted through the

Fig. 1.* Felt-Waterproofing for Foundations

or other pipes to some central sump from which it is mechanically pumped to a sewer. The purpose of the waterproofing in this case, therefore, is to concentrate or drive the water to this sump. For shallow cellars and especially dampproofing-work, this tar-and-felt method is the most economical and most frequently employed.

Waterproofing by Coating with Water-Proof Cement. For deep and difficult work a comparatively new method of waterproofing is often used (Fig 2). This consists of placing a coating of water-proof cement upon the interior surface of the exterior walls of the building and over the upper surface of the concrete floor-slab in the basement or subbasement. Fig. 3 shows a foundation for an engine, the concrete being waterproofed as shown. The pit is made somewhat larger than the foundation, the extra space being filled in with cinders, dry bricks or terra-cotta blocks, which may be readily removed to allow access to the bed-plate bolts for which hand-holes have been cast in the concrete, thus permitting the complete removal of the engine. The figure

found in solution with water in soil. By the cement method the cost of rick supporting walls and the concrete supporting slab is eliminated as is he corresponding cost of the necessary excavation for them; and finally, aterproofing on the floor serves the double purpose of waterproofing and ng-surface, thus saving the cost of the cement finish usually found in nents and subbasements. One of the disadvantages of cement water- ing is that the material is rigid and is fractured by any settlement of the ing or contraction in the concrete upon which it is placed. Experience has n, however, that settlement-cracks usually take place before the water- ing contractor has left the building and that there is little or no trouble these causes after his work is completed. Contraction-cracks in concrete, ver, seem to develop at any time within twenty-four months after concrete een placed. In order to prevent these cracks, users of the cement water- ing have adopted a system of reinforcement in the concrete, and it is claimed this reinforcement is, in the long run, an economy, as it permits of less con- and gives a better and stronger floor or wall. On brick and stone walls ouble is experienced from contraction and expansion. It should be re- bered that this work is all below grade where contraction and expansion educed to a minimum, regardless of the materials used.

aterproofing by Adding Substances to Cement. This is another od of waterproofing now being advocated by some. If this method could ys be made efficient, it would be highly advantageous. It is claimed by nanufacturers of these compounds that in order to secure a water-proof nent, for example, a certain percentage of the compound is to be mixed the cement before it is incorporated in the concrete. The opponents of method claim, however, that it is impossible to construct a basement in way without incurring the danger of serious leaks at the joinings of one work with that of another; that leakage at these points of cleavage may creased by the use of waterproofing-compounds; and that their principal is that they produce a very dense mass of concrete. It is always difficult nd old concrete to new, and if concrete is made water-proof, or, in other s, nonabsorbent, the difficulty of joining new concrete to a nonabsorbent of old concrete is increased. This method is effective, however, and is to commended in work which can be carried on without interruption, such, for nce, as small elevator-pits or small swimming-pools, where the concrete e started in the morning and completed by night or before any part of the has had time to attain its initial set.

FORCE OF THE WIND

lation Between the Pressure and Velocity of Wind. According to riments made in 1890 or thereabouts, by C. F. Marvin, United States l Service, the relation between wind-pressure and velocity is given very ately by the formula $p = 0.004\ V^2$, where p is the pressure in pounds per re foot on a flat surface normal to the direction of the wind, and V the ity of the wind in miles per hour. Smeaton considered the pressure as l to $0.005\ V^2$. The following table, based on Marvin's formula,* is quoted urneaure and Ketchum.†

* Marvin's formula is written $p = 0.0032\ V^2$ the values in this table will be slightly ged. See Chapter XXVII, pages 1052 and 1053; Chapter XXX, page 1199; and also 1394. [1] The formula used by the United States Signal Service is $p = 0.004\ V^2$. The pressure is probably somewhere between $0.005\ V^2$ and $0.004\ V^2$, near the former for low velocities and near the latter for high velocities.

† ee, also, Trautwine's Pocket-Book, page 321.

Table Showing the Force of the Wind

Miles per hour	Feet per minute	Feet per second	Force, in pounds, per square foot	Description
1	88	1.47	0.004	Hardly perceptible
2	176	2.93	0.014	Just perceptible
3	264	4.40	0.036	
4	352	5.87	0.064	Gentle breeze
5	440	7.33	0.1	
10	880	14.67	0.4	Pleasant breeze
15	1 320	22.0	0.9	
20	1 760	29.3	1.6	Brisk gale
25	2 200	36.6	2.5

COPIES OF TRACINGS

Blue-Prints from Tracings. The following directions * cover the wh ground. The sensitized paper can be procured, all prepared, at stores wh artists' materials are sold, so that the process of preparing the paper by me of chemicals can then be omitted. The materials required are as follows:

(1) A board a little larger than the tracing to be copied. The draw board on which the drawing and tracing are made can always be used.

(2) Two or three thicknesses of flannel or other soft white cloth, which is be smoothly tacked to the board to form a smooth surface, on which to lay t sensitized paper and tracing while printing.

(3) A plate of common double-thick window-glass, of good quality, sligh larger than the tracing to be copied. The function of the glass is to keep t tracing and sensitized paper closely and smoothly pressed together wh printing.

(4) The chemicals for sensitizing the paper. These consist simply of eq parts, by weight, of citrate of iron and ammonia, and red prussiate of pot and can be obtained at any drug-store. The price should not be over $ 10 cts per ounce for each.

(5) A stone or yellow-glass bottle to keep the solution of the above chemic in. If there is but little copying to do, an ordinary glass bottle will do, and t solution can be freshly made whenever it is wanted for immediate use.

(6) A shallow earthen dish in which to place the solution when using it. common dinner-plate is as good as anything for this purpose.

(7) A soft paste-brush, about 4 in wide.

(8) Plenty of cold water in which to wash the copies after they have b exposed to the sunlight. The outlet of an ordinary sink may be closed placing a piece of paper over it with a weight on top to keep the paper do and the sink filled with water, if the sink is large enough to lay the copy

* Taken from The Locomotive.

If it is not, it is better to make a water-tight box 5 or 6 in deep, and 6 in wider and longer than the drawing to be copied.

(9) A good quality of white book-paper.

The following directions are to be followed:

Dissolve the chemicals in cold water in these proportions: 1 oz of citrate of iron and ammonia; 1 oz of red prussiate of potash; and 8 oz of water. They may all be put into a bottle together and shaken up. Ten minutes will suffice to dissolve them.

Lay a sheet of the paper to be sensitized on a smooth table or board, pour a little of the solution into the earthen dish or plate, and apply a good even coating of it to the paper with the brush. Then tack the paper to a board by two adjacent corners, and set it in a dark place to dry. One hour is sufficient for the drying. Place the paper, with its sensitized side up, on the board on which you have smoothly tacked the white flannel cloth; lay the tracing to be copied on top of it; on top of all lay the glass plate, being careful that paper and tracing are both smooth and in perfect contact with each other, and lay the whole thing out in the sunlight. Between eleven and two o'clock in the summer-time, on a clear day, from 6 to 10 minutes will be sufficiently long to expose it; at other seasons a longer time will be required. If the location does not admit of direct sunlight, the printing may be done in the shade, or even on a cloudy day; but from 1 to 2½ hours will be required for exposure. A little experience will soon enable any one to judge of the proper time for exposure on different days. After exposure, place the print in the sink or trough of water before mentioned, and wash thoroughly, letting it soak from 3 to 5 minutes. Upon immersion in the water, the drawing, hardly visible before, will appear in clear white lines on a dark-blue ground. After washing, tack up against the wall, or other convenient place, by the corners, to dry. This finishes the operation, which is very simple and thorough. After the copy is dry, it can be written on with a common pen and a solution of common soda, which makes a white line.

Alternate Recipe for Making Blue-Prints. The following is an alternative recipe to the one given above. The paper should be prepared by floating it for one minute in a solution of ferricyanide of potassium (red prussiate of potash), 1 oz, and water, 5 oz. It should then be dried in a dark room, afterwards exposed beneath the negative until the dark shades have assumed a deep blue color, and immersed in a solution of water, 2 oz, and bichloride of mercury, 1 gr. The print should be washed, immersed in a hot solution of oxalic acid, 4 drm, and water, 4 oz, washed again and dried. Where a copy of a drawing is to be made the prepared paper is placed, sensitive side uppermost, on a flat board covered with two or three thicknesses of blanket or its equivalent. A tracing of the drawing is made, laid on the sensitized paper and held in place by a sheet of glass clamped to the board. The sensitized paper is exposed to the sunlight from 4 to 10 minutes or to a clear sky from 20 to 30 minutes and then removed, washed and dried. The only requisite as to paper is that it must stand washing. Prepared paper may be purchased.

Black-Line Copies from Tracings.* The directions for making the sensitizing solution used in this process are as follows: Dissolve separately, gum arabic, 13 dr, in 17 oz water; tartaric acid, 13 dr, in 6 oz 6 dr water; persulphate of iron, 8 dr, in 6 oz 6 dr of water. Pour the third solution into the second, stir thoroughly, and then pour the resulting mixture into the first, the stirring being continued. When the mixture is complete, add slowly, still stirring, 3 fl oz and 3 drm of liquid perchloride of iron; filter into a bottle and keep in the dark. Use a strong well-sized paper, apply a thin, smooth coat of the solution with a large brush or sponge, and then dry in a dark room with moderate heat. The

* There is as yet no known recipe resulting in jet-black lines.

paper should be yellowish in tint and will not keep long. Place the tracing made with very black ink, in the printing-frame, the drawing being in close contact with the glass, and place over it the sensitized paper, with the prepared side in contact with the back of the tracing. After an exposure of 10 or 12 minutes, the print should show a yellow drawing on a white ground. Take the print from the frame and float for a minute, face down, in a developing bath of gallic acid, or tannin, from 31 to 46 gr; oxalic acid, 1¼ gr; and water, 34 oz. Then plunge it in clear water, rinse well and dry. The orange-yellow lines will be changed into a purplish-black.

Brown-Line Copies from Tracings. The directions for making the sensitizing solution used in this process are as follows: Dissolve gelatine, 6 gr; water, 1 oz; swell in cold water, give water-bath and add tartaric acid, 8 oz; silver nitrate, 9 gr; and ammonia citrate of iron, 40 gr. Filter in a subdued light. Print in a bright light until slightly darker than ordinary printing-out paper; wash for 5 minutes; immerse in a 2½% solution of hypo until desired color is obtained; and wash and dry. Blue-prints may be turned to a rich-brown color by immersing in a solution of caustic soda the size of a bean dissolved in 5 oz of water, until the blue has changed to orange-yellow. They are then washed thoroughly, immersed in a bath of water in which has been dissolved a heaping teaspoonful of tannic acid, rinsed in clear water and dried. Paper may be sized for brown-prints by soaking it in a mixture of 90 gr of arrowroot and 5 oz of cold water, rubbed into a cream and mixed with 20 gr of glucose and 5 oz of hot water. The mixture should be boiled 2 minutes and then permitted to cool before use.

HORSE-POWER,* PULLEYS, GEARS, BELTING AND SHAFTING

Horse-Power. A horse can travel 400 yd at a walk in 4½ min, at a trot in 2 min, and at a gallop in 1 min; he occupies at a picket 3 ft by 9 ft; and his average weight is 1 000 lb. An AVERAGE HORSE carrying 225 lb can travel 25 miles in a day of 8 hr. A DRAUGHT-HORSE can draw 1 600 lb 23 miles a day, weight of carriage included. In a HORSE-MILL a horse moves at the rate of 3 ft in a second. The diameter of the track should not be less than 25 ft.

A Horse-Power, in Machinery, is estimated at 33 000 lb, raised 1 ft in a minute; but as a horse can exert that force but 6 hr a day, one MACHINERY HORSE-POWER is equivalent to that of four horses.

Rules to Determine the Size and Speed of Pulleys or Gears. The driving-pulley is called the DRIVER, and the driven pulley the DRIVEN. If the number of teeth in the gears are used instead of the diameter, in these calculations, number of teeth must be substituted wherever diameter occurs.

(1) **To Find the Diameter of the Driver,** the diameter of the driven and its revolutions, and also revolutions of driver, being given. Multiply the diameter of the driven by its revolutions, and divide the product by the revolutions of the driver; the quotient will give the diameter of the driver.

(2) **To Find the Diameter of the Driven,** the revolutions of the driven, also the diameter and revolutions of the driver, being given. Multiply the diameter of the driver by its revolutions, and divide the product by the revolutions of the driven; the quotient will give the diameter of the driven.

(3) **To Find the Revolutions of the Driver,** the diameter and revolutions of the driven, also the diameter of the driver, being given. Multiply the diameter

* See, also, pages 1274 and 1397.

of the driven by its revolutions, and divide the product by the diameter of the driver; the quotient will give the revolutions of the driver.

(4) **To Find the Revolutions of the Driven,** the diameter and revolutions of the driver, also the diameter of the driven, being given. Multiply the diameter of the driver by its revolutions, and divide the product by the diameter of the driven; the quotient will give the revolutions of the driven.

Horse-Power Transmitted by Belting. The efficiency of belting to transmit power, or to turn a wheel or PULLEY, depends upon the width and thickness of the belt, the arc-contact with the pulley, the position of the belt, whether horizontal, vertical, or at an angle, and the velocity. The greater the velocity and the thicker the belt, the more power it will transmit. A belt running vertically or inclined will transmit less power than one running horizontally, but in figuring the horse-power capacity of belting only the velocity, width and thickness of belt are usually considered, it being assumed that the pulleys are of proper size and located so that the belt will be nearly horizontal. Belts are commonly assumed to be of LEATHER, unless otherwise designated. The term SINGLE BELT is used to designate a belt made of a single thickness of cowhide leather. A DOUBLE BELT is made by cementing and riveting together two thicknesses of leather. There is no standard thickness for either single or double belts.

Rules. Many rules have been given for determining the horse-power that belting will transmit.* Those commonly used are:

(1) For Single Belts. Multiply the width, in inches, by the velocity in feet per minute and divide by 1 000.

(2) For Double Belts. Multiply the width by the velocity and divide by 700. The answer is the number of horse-powers.

Some authorities give divisors of 800 and 733 for single belts, and 550 and 513 for double belts. For the velocity of the belt multiply the number of revolutions per minute of either pulley by the circumference of that pulley.

Notes on Belting. For continuous use a double belt is the most economical in the long run, except on very small pulleys or for very light duty. Triplex and quadruple belts are sometimes used for very heavy duty, but such belts are not commonly carried in stock. Single belts should always be used with the hair-side next the pulley. The belt-speed for maximum economy should be from 4 000 to 4 500 ft per minute. IDLER-PULLEYS work most satisfactorily when located on the slack side of the belt about one-quarter way from the driving-pulley. Belts are more durable and work more satisfactorily when made narrow and thick than when made wide and thin. As belts increase in width they should also be made thicker. For dynamo-work or electric motors the ends of the belt should be fastened together by splicing and cementing instead of by lacing. For all other cases the ends are fastened by hooks or lacing. Belts should be cleaned and greased every 5 to 6 months.

Distance from Center to Center of Shafts.* In locating shafts that are to be connected with each other by belts, care should be taken to separate them by a proper distance. This distance should be such as to allow a gentle sag to the belt when in motion.

Rule. A general rule may be stated thus: Where narrow belts are to be run over small pulleys, 15 ft is a good average, the belt having a sag of from 1½ to 2 in. The minimum distance between shafts is about 10 ft. For larger belts, working on larger pulleys, a distance of from 20 to 25 ft does well, with a sag

* For a discussion of belting, belt-dressing, care of belting, shafting, etc., see Kent's Mechanical Engineers' Pocket-Book.

of from 2½ to 4 in. For main belts, working on very large pulleys, the distance should be from 25 to 30 ft, the belts working well with a sag of from 4 to 5 in. If too great a distance is attempted, the belt will have an unsteady flapping motion, which will destroy both the belt and the machinery.

Arrangement of Belts and Pulleys.* If possible to avoid it, connected shafts should never be placed one directly over the other, as in such case the belt must be kept very tight to do the work. For this purpose belts should be carefully selected of well-stretched leather. It is desirable that the angle of the belt with the floor should not exceed 45°. It is also desirable to locate the shafting and machinery so that belts will run off from each shaft in opposite directions, as this arrangement will relieve the bearings from the friction that would result if all pulled one way on the shaft. If possible, machinery should be so placed that the direction of the belt-motion will be from the top of the driving to the top of the driven pulley, so that the sag will increase the arc of contact. The pulley should be a little wider than the belt required for the work, and should have a crowning face, except where the belt is to be shifted. The motion of driving should run with and not against the laps of the belts.

Rubber Belts are cheaper than leather belts and should always be used in wet places, but for ordinary use in dry places they are not as durable as leather belts. They should always be kept free from grease or animal oils. If they slip, their inside surfaces should be moistened with boiled linseed-oil. Some fine chalk, sprinkled on over the oil, will help the belt.

Rule for Finding the Lengths of Belts. Add the diameter of the two pulleys together, multiply by 3⅐, divide the product by 2, add to the quotient twice the distance between the center of the shafts, and the sum will be the required length.

The Horse-Power that Shafting will Transmit

Diameter of shaft		Revolutions per minute

CHAIN-BLOCKS, HOISTS, HOOKS, ETC.

neral Description. These are portable hoisting-devices which enable one to raise a very heavy load and which sustain the load at any point. In al, they resemble pulleys operated by chains. Since the invention of the ential pulley-block by T. A. Weston, about the year 1863, chain-blocks come into very general use for economical hoisting, particularly where it is ed to hold the load at any point. Chain-blocks are of three general classes:
The Differential Block. This is the original and the simplest and cheap- rm of self-sustaining pulley;
The Screw-Block or Worm-Geared Block. Of these, the Yale & Towne x block is the most efficient type;
The Triplex Block. This is spur-geared.
fferential and worm-geared blocks of all kinds depend upon friction to pre- the load from running down. In the triplex block a separate device is duced which automatically holds the load safely, and yet enables it to be ed with slight effort and at high velocity but without acceleration or danger. is the most efficient of all chain-blocks, and the most economical wherever : work is wanted and economy in time and labor sought. For information the kind of block best adapted to any particular service, the manufacturers ld be consulted. The following data on the power and efficiency of chain- s were supplied by the Yale & Towne Manufacturing Company.

wer and Efficiency of Chain-Hoists. The table below gives the work done by the operator at the hand-pulling chain with each size of the various of chain-blocks in lifting the stated capacity, that is, the amount of work lling required to lift this load ONE FOOT by stating the force exerted in ds and the distance in feet of operating-chains to be pulled. The product se two factors determines the efficiency of the block and the ease and speed isting. The 12, 16, and 20-ton-capacity chain-blocks have each two hand- s.

Work Done by Operator with Chain-Blocks

Capacity, tons	Triplex spur-geared, lb ft	Duplex worm-geared, lb ft	Differential lb ft
½	62× 21	68× 40	122×24
1	82× 31	87× 59	216×30
1½	110× 35	94× 80	246×36
2	120× 42	115× 93	308×42
3	114× 69	132×126	557×38
4	124× 84	142×155	....
5	110×126	145×195	....
6	130×126	145×252	....
8	135×168	160×310	....
10	140×210	160×390	....
12	130×126	....	....
16	135×168	....	....
20	140×210	....	....

e capacities are given in tons. The figures give the number of feet to perated on each hand-chain. A man cannot pull more than his own ht on the operating chains, and can pull faster in proportion as the pull ired is lighter. The maximum pull usually required of one man is 82 lb, he will do more work with less fatigue if the hand-chain pull is not over

40 lb, because he can then pull the chain hand over hand a little more than as fast as he could when pulling twice as hard. When the hand-chain pull is less than 20 lb the speed of hoisting an equal load is diminished, because the man is tired by moving his arms too rapidly, and cannot do as much work as with a heavier pull. The best result is obtained by using a chain-block which has a capacity of double the usual load. The operator then works to the best advantage with average loads, and occasional heavy loads are easily handled without overstraining either the operator or the chain-block, which should never be used beyond its capacity for fear of straining the chain so that it will not run smoothly.

Proportions of Hooks.* For convenience of manufacture hooks of different sizes are made from some regular commercial size of round iron. The basis, or initial point, in each case is, therefore, the size of the iron of which the hook is to be made, and it is indicated by the dimension A in the diagram. The dimension D is arbitrarily assumed. The other dimensions, as given by the formulas, are those which, while preserving a proper bearing face on the interior of the hook for the ropes or chains which may be passed through it, give the greatest resistance to spreading and ultimate rupture which the amount of material in the original bar admits of. The symbol Δ is used in the formulas to indicate the NOMINAL CAPACITY of the hook in tons of 2 000 lb. The formulas which determine the lines of the other parts of the hooks of the several sizes are as follows, all the measurements being expressed in inches:

$D = 0.5\,\Delta + 1.25$	$G = 0.75\,D$
$E = 0.64\,\Delta + 1.60$	$O = 0.363\,\Delta + 0.66$
$F = 0.33\,\Delta + 0.85$	$Q = 0.64\,\Delta + 1.60$
$H = 1.08\,A$	$L = 1.05\,A$
$I = 1.33\,A$	$M = 0.50\,A$
$J = 1.20\,A$	$N = 0.85\,B - 0.16$
$K = 1.13\,A$	$U = 0.866\,A$

Example. To find the dimension D, for a 2-ton hook. The formula is

$$D = 0.5\,\Delta + 1.25$$

and as $\Delta = 2$, the dimension D by the formula is found to be 2¼ in. The dimensions A, are necessarily based upon the ordinary merchant sizes of round iron. The sizes which it has been found best to select are the following:

Capacities of hooks	⅛	¼	½	1	1½	2	3	4	5	6	8	10	tons
Dimension A	⅝	11/16	¾	1 1/16	1¼	1⅜	1¾	2	2¼	2½	2⅞	3¼	inches

The formulas which give the sections of the hook at the several points are all expressed in terms of A, and can therefore be readily ascertained by reference to the foregoing scale.

* By Henry R. Towne, in his Treatise on Cranes, which includes the results of extensive experimental and mathematical investigation.

ɪmple. To find the dimension I, in a 2-ton hook. The formula is

$$I = 1.33\,A$$

or a 2-ton hook, $A = 1\frac{3}{8}$ in. Therefore I, in a 2-ton hook, is found to be in.

anner of Failure of Hooks. Experiment has shown that hooks made ding to the above formulas will give way first by the opening of the jaw, ı, however, will not occur except with a load much in excess of the nominal ity of the hook. This yielding of the hook when overloaded becomes a e of safety, as it constitutes a signal of danger which cannot easily be overd, and which must proceed to a considerable length before rupture occurs the load is dropped. A comparison of these hooks with most of those in ary use shows that the latter are, as a rule, badly proportioned, and fretly dangerously weak.

BELLS

† This bell is fractured and has not been rung for many years.

SYMBOLS FOR THE APOSTLES AND SAINTS

om the constant occurrence of symbols in the edifices of the Middle Ages nany of the cathedrals of the present day, the following list of symbols, as nonly attached to the apostles and saints, may be found useful:

Holy Apostles

eter. Bears a key, or two keys with different wards.
ndrew. Leans on a cross so called from him; called by heralds the saltire.
ohn the Evangelist. With a chalice, in which is a winged serpent. When this symbol is used, the eagle, another symbol of him, is never given.
artholomew. With a flaying-knife.
ames the Less. A fuller's staff bearing a small square banner.
ames the Greater. A pilgrim's staff, hat and escalop-shell.
homas. An arrow, or with a long staff.
imon. A long saw.
ude. A club.
Iatthias. A hatchet.
hilip. Leans on a spear or has a long cross in the shape of a T.
Iatthew. A knife or dagger.
Iark. A winged lion.
uke. A bull.
ohn. An eagle.
aul. An elevated sword, or two swords in saltire.
ohn the Baptist. An Agnus Dei.
tephen. With stones in his lap.

Saints

gnes. A lamb at her feet.
ecilia. With an organ.
lement. With an anchor.
avid. Preaching on a hill.
enis. With his head in his hands.
eorge. With the dragon.
licholas. With three naked children in a tub, in the end whereof rests his pastoral staff.
incent. On the rack.

IRCULAR OF ADVICE RELATIVE TO PRINCIPLES OF PROFESSIONAL PRACTICE AND THE CANONS OF ETHICS, BY THE AMERICAN INSTITUTE OF ARCHITECTS *

A Circular of Advice

troductory. The American Institute of Architects, seeking to maintain a standard of practice and conduct on the part of its members as a safeguard e important financial, technical and esthetic interests entrusted to them, s the following advice relative to professional practice: The profession of itecture calls for men of the highest integrity, business capacity and artistic

* The American Institute of Architects, Document No. 141, Washington, D. C., 29, 1919. Reprinted by permission. This circular relates to the principles of sional practice and the canons of ethics.

ability. The architect is entrusted with financial undertakings in which honesty of purpose must be above suspicion; he acts as professional adviser to his client and his advice must be absolutely disinterested; he is charged with the exercise of judicial functions as between client and contractors and must act with entire impartiality; he has moral responsibilities to his professional associates and subordinates; finally, he is engaged in a profession which carries with it grave responsibility to the public. These duties and responsibilities cannot be properly discharged unless his motives, conduct and ability are such as to command respect and confidence. No set of rules can be framed which will particularize all the duties of the architect in his various relations to his clients, to contractors, to his professional brethren, and to the public. The following principles should, however, govern the conduct of members of the profession and should serve as a guide in circumstances other than those enumerated:

(1) **On the Architect's Status.** The architect's relation to his client is primarily that of PROFESSIONAL ADVISER; this relation continues throughout the entire course of his service. When, however, a contract has been executed between his client and a contractor by the terms of which the architect becomes the official interpreter of its conditions and the judge of its performance, an additional relation is created under which it is incumbent upon the architect to side neither with client nor contractor, but to use his powers under the contract to enforce its faithful performance by both parties. The fact that the architect's payment comes from the client does not invalidate his obligation to act with impartiality to both parties.

(2) **On Preliminary Drawings and Estimates.** The architect at the outset should impress upon the client the importance of sufficient time for the preparation of drawings and specifications. It is the duty of the architect to make or secure PRELIMINARY ESTIMATES when requested, but he should acquaint the client with their conditional character and inform him that complete and final figures can be had only from complete and final drawings and specifications. If an unconditional limit of cost be imposed before such drawings are made and estimated, the architect must be free to make such adjustments as seem to him necessary. Since the architect should assume no responsibility that may prevent him from giving his client disinterested advice, he should not, by bond or otherwise, guarantee any estimate or contract.

(3) **On Superintendence and Expert Services.** On all work except the simplest, it is to the interest of the owner to employ a SUPERINTENDENT or CLERK OF THE WORKS. In many engineering problems and in certain specialized problems, it is to his interest to have the services of special experts and the architect should so inform him. The experience and special knowledge of the architect make it to the advantage of the owner that these persons, although paid by the owner, should be selected by the architect under whose direction they are to work.

(4) **On the Architect's Charges.** The SCHEDULE OF CHARGES of the American Institute of Architects is recognized as a proper minimum of payment. The locality or the nature of the work, the quality of services to be rendered, the skill of the practitioner or other circumstances frequently justify a higher charge than that indicated by the schedule.

(5) **On Payment for Expert Service.** The architect when retained as an EXPERT, whether in connection with competitions or otherwise, should receive a compensation proportionate to the responsibility and difficulty of the service. No duty of the architect is more exacting than such service, and the

ofession is involved in it. Under no circumstances should experts know-
name prices in competition with each other.

On Selection of Bidders or Contractors. The architect should advise ent in the selection of BIDDERS and in the AWARD OF THE CONTRACT. In ng that none but trustworthy bidders be invited and that the award be only to contractors who are reliable and competent, the architect protects erests of his client.

On Duties to the Contractor. As the architect decides whether or e intent of his plans and specifications is properly carried out, he should pecial care to see that these drawings and specifications are complete and te, and he should never call upon the contractor to make good oversights rs in them nor attempt to shirk responsibility by indefinite clauses in the ct or specifications.

On Engaging in the Building Trades. The architect should not directly irectly engage in any of the BUILDING TRADES. If he has any financial t in any building material or device, he should not specify or use it without owledge and approval of his client.

On Accepting Commissions or Favors. The architect should not any COMMISSION or any substantial service from a contractor or from terested person other than his client.

On Encouraging Good Workmanship. The large powers with which chitect is invested should be used with judgment. While he must con- bad work, he should commend good work. Intelligent initiative on the craftsmen and workmen should be recognized and encouraged and the ct should make evident his appreciation of the dignity of the ARTISAN'S ION.

On Offering Services Gratuitously. The seeking out of a possible and the offering to him of professional services on approval and WITHOUT NSATION, unless warranted by personal or previous business relations, o lower the dignity and standing of the profession and is to be condemned.

On Advertising. Publicity of the standards, aims and progress of the ion, both in general and as exemplified by individual achievement, is al. Advertising of the individual, meaning self-laudatory publicity ed by the person advertised or with his consent, tends to defeat its own to the individual as well as to lower the dignity of the profession, and is leplored.

On Signing Buildings and Use of Titles. The unobtrusive SIGNATURE LDINGS after completion is desirable. The placing of the ARCHITECT'S ON A BUILDING DURING CONSTRUCTION serves a legitimate purpose for information, but it is to be deplored if done obtrusively for individual ty. The use of INITIALS designating membership in the Institute is le in all professional relationships, in order to promote a general under- g of the Institute and its standards through a knowledge of its members eir professional activities. Upon the members devolves the responsibility ciate the symbols of the Institute with acts representative of the highest rds of professional practice.

On Competitions. An architect should not take part in a competition MPETITOR or JUROR unless the competition is to be conducted according best practice and usage of the profession, as evidenced by its having d the approval of the Institute, nor should he continue to act as PRO- NAL ADVISER after it has been determined that the program cannot be so

drawn as to receive such approval. When an architect has been auth submit sketches for a given project, no other architect should submit for it until the owner has taken definite action on the first sketches, far as the second architect is concerned, a competition is thus esta Except as an authorized competitor, an architect may not attempt to work for which a competition has been instituted. He may not atte influence the award in a competition in which he has submitted drawings may not accept the commission to do the work for which a competition has instituted if he has acted in an advisory capacity either in drawing the pro or in making the award.

(15) **On Injuring Others.** An architect should not falsely or mali injure, directly or indirectly, the professional reputation, prospects or bu of a fellow architect.

(16) **On Undertaking the Work of Others.** An architect should not take a commission while the claim for compensation or damages or b an architect previously employed and whose employment has been term remains unsatisfied, unless such claim has been referred to arbitration or has been joined at law; or unless the architect previously employed ne to press his claim legally; nor should he attempt to supplant a fellow arc after definite steps have been taken toward his employment.

(17) **On Duties to Students and Draughtsmen.** The architect s advise and assist those who intend making architecture their career. I beginner must get his training solely in the office of an architect, the latter s assist him to the best of his ability by instruction and advice. An arc should urge his draughtsmen to avail themselves of educational opportun He should, as far as practicable, give encouragement to all worthy agencie institutions for architectural education. While a thorough technical pr ation is essential for the practice of architecture, architects cannot too str insist that it should rest upon a broad foundation of general culture.

(18) **On Duties to the Public and to Building Authorities.** An a tect should be mindful of the public welfare and should participate in movements for public betterment in which his special training and exp quality him to act. He should not, even under his client's instructions, in or encourage any practices contrary to law or hostile to the public in for as he is not obliged to accept a given piece of work, he cannot, by urg he has but followed his client's instructions, escape the condemnation at to his acts. An architect should support all public officials who have of building in the rightful performance of their legal duties. He shoul fully comply with all building laws and regulations, and if any such ap him unwise or unfair, he should endeavor to have them altered.

(19) **On Professional Qualifications.** The public has the right to that he who bears the TITLE OF ARCHITECT has the knowledge and ability for the proper invention, illustration and supervision of all building op which he may undertake. Such qualifications alone justify the assum the title of architect.

The Canons of Ethics *

The following Canons are Adopted by The American Insti Architects as a general guide, yet the enumeration of particular duties

* Adopted, December 14–16, 1909. Revised, December 10–12, 1912. Revis 26, 1918.

ot be construed as a denial of the existence of others equally important although ot specially mentioned. It should also be noted that the several sections dicate offenses of greatly varying degrees of gravity. It is unprofessional for architect

(1) To engage directly or indirectly in any of the building or decorative trades.

(2) To guarantee an estimate or contract by bond or otherwise.

(3) To accept any commission or substantial service from a contractor or om any interested party other than the owner.

(4) To take part in any competition which has not received the approval of e Institute or to continue to act as professional adviser after it has been dermined that the program cannot be so drawn as to receive such approval.

(5) To attempt in any way, except as a duly authorized competitor, to cure work for which a competition is in progress.

(6) To attempt to influence, either directly or indirectly, the award of a comtition in which he is a competitor.

(7) To accept the commission to do the work for which a competition has been stituted if he has acted in an advisory capacity, either in drawing the proam or in making the award.

(8) To injure falsely or maliciously, directly or indirectly, the professional putation, prospects, or business of a fellow architect.

(9) To undertake a commission while the claim for compensation, or damages, both, of an architect previously employed and whose employment has been rminated remains unsatisfied, until such claim has been referred to arbitration issue has been joined at law, or unless the architect previously employed glects to press his claim legally.

(10) To attempt to supplant a fellow architect after definite steps have been ken toward his employment, that is, by submitting sketches for a project for ich another architect has been authorized to submit sketches.

(11) To compete knowingly with a fellow architect for employment on the sis of professional charges.

ofessional Practice of Architects. Details of Service to be Rendered and Schedule of Proper Minimum Charges *

(1) The architect's professional services consist of the necessary conferences, e preparation of preliminary studies, working drawings, specifications, largele and full-size detail drawings; the drafting of forms of proposals and ntracts; the issuance of certificates of payment; the keeping of accounts, the neral administration of the business and supervision of the work, for which, cept as hereinafter mentioned, the minimum charge, based upon the total t of the work † complete, is 6 per cent.

(2) On residential work, alterations to existing buildings, monuments, furnie, decorative and cabinetwork and landscape-architecture, it is proper to ke a higher charge than above indicated.

* As adopted at the Washington, D. C., Convention, December 15–17, 1908, and revised in form at the Minneapolis convention, December 6–8, 1916.

† The words "the cost of the work," as used in Articles (1) and (9) hereof, are ordinarily be interpreted as meaning the total of the contract-sums incurred for the execution of work, not including architect's and engineer's fees or the salary of the clerk of the ks, but in certain rare cases, that is, when labor or material is furnished by the owner w its market cost or when old materials are reused, the cost of the work is to be erpreted as the cost of all materials and labor necessary to complete the work, as h cost would have been if all materials had been new and if all labor had been fully d at market prices current when the work was ordered, plus contractor's profits and enses

(3) The architect is entitled to compensation for articles purchased u his direction, even though not designed by him.

(4) Where the architect is not otherwise retained, consultation-fees for pro fessional advice are to be paid in proportion to the importance of the quest involved and services rendered.

(5) The architect is to be reimbursed for the costs of transportation a living incurred by him and his assistants while traveling in discharge of du connected with the work, and the costs of the services of heating, ventilati mechanical, and electrical engineers.

(6) The rate of percentage arising from Articles (1) and (2) hereof, that the basic rate, applies when all of the work is let under one contract. Shoul the owner determine to have certain portions of the work executed und separate contracts, as the architect's burden of service, expense, and respon bility is thereby increased, the rate in connection with such portions of the wo is greater (usually by 4 per cent) than the basic rate. Should the owner dete mine to have substantially the entire work executed under separate contrac then such higher rate applies to the entire work. In any event, however, t basic rate, without increase, applies to contracts for any portions of the wor on which the owner reimburses the engineer's fees to the architect.

(7) If, after a definite scheme has been approved, the owner makes a decisi which, for its proper execution, involves extra services and expense for chang in or additions to the drawings, specifications, or other documents; or if a con tract be let by cost of labor and materials plus a percentage or fixed sum; or i the architect be put to labor or expense by delays caused by the owner or a con tractor, or by the delinquency or insolvency of either, or as a result of damage b fire, he is to be equitably paid for such extra service and expense.

(8) Should the execution of any work designed or specified by the archite or any part of such work be abandoned or suspended, the architect is to be pai in accordance with or in proportion to the terms of Article (9) of this Schedu for the service rendered on account of it, up to the time of such abandonment o suspension.

(9) Whether the work be executed or whether its execution be suspended o abandoned in part or whole, payments to the architect on his fee are subje to the provisions of Articles (7) and (8), made as follows: Upon completi of the preliminary studies, a sum equal to 20 per cent of the basic rate compu upon a reasonable estimated cost. Upon completion of specifications and ge eral working drawings (exclusive of details) a sum sufficient to increase pa ments on the fee to sixty per cent of the rate or rates of commission agreed up as influenced by Article (6), computed upon a reasonable cost estimated o such completed specifications and drawings, or if bids have been receiv then computed upon the lowest bona-fide bid or bids. From time to tim during the execution of work and in proportion to the amount of service re dered by the architect, payments are made until the aggregate of all paymen made on account of the fee under this Article reaches a sum equal to the ra or rates of commission agreed upon as influenced by Article (6), computed up the final cost of the work. Payments to the architect, other than those on h fee, fall due from time to time as his work is done or as costs are incurred. N deduction is made from the architect's fee on account of penalty, liquidat damages or other sums withheld from payments to contractors.

(10) The owner is to furnish the architect with a complete and accura survey of the building-site, giving the grades and lines of streets, paveme and adjoining properties; the rights, restrictions, easements, boundaries a contours of the building-site, and full information as to sewer, water, gas a

ctrical service. The owner is to pay for borings or test-pits and for chemical echanical or other tests, when required.

(11) The architect endeavors to guard the owner against defects and deiencies in the work of contractors, but he does not guarantee the performance their contracts. The supervision of an architect is to be distinguished from continuous personal superintendence to be obtained by the employment a clerk of the works. When authorized by the owner, a clerk of the works, eptable to both owner and architect, is to be engaged by the architect at a ary satisfactory to the owner and paid by the owner, upon presentation of architect's monthly certificates.

(12) When requested to do so, the architect makes or procures preliminary imates on the cost of the work and he endeavors to keep the actual cost of work as low as may be consistent with the purpose of the building and with per workmanship and material, but no such estimate can be regarded as er than an approximation.

(13) Drawings and specifications, as instruments of service, are the property the architect, whether the work for which they are made be executed or not.

ARCHITECTURAL COMPETITIONS *

This Circular of Advice furnishes information as to the best methods of iducting architectural competitions and states the conditions which are prequisite to participation in them by members of The American Institute of chitects. It does not apply to competitions for work to be erected elsewhere n in the United States, its territories and possessions.

The Attitude of The American Institute of Architects to Competitions. ce its foundation, more than sixty years ago (1857), The American Institute Architects has given much attention to the conduct of ARCHITECTURAL COMPITIONS. These contests, instituted when the direct selection of an architect ld not be made, were for many years conducted without proper regulation l often in disregard of the interests both of the owner and of the competitors. e owner, totally unfamiliar with the intricacies of the subject, assumed, with- skilled assistance, to prepare the programme, laying down, or more frequently oring, rules to govern procedure. With the growth of the country, the inase in expenditures for public and private buildings, and the increase in the nber of architects, all the evils of ill-regulated competitions became more rked. Programmes varied from loose and careless forms, difficult to undernd and often open to the suspicion that only the initiated knew what they ant, to over-elaborate ones necessitating useless study of details and needless wings. Those instituting the competition often had no legal authority to pay competitors, still less to employ the winner. There was great economic ste, the total cost of participation exceeding the total net profit accruing to the fession from work secured through competitions. Architects have learned t the outcome of a competition, unless governed by well-defined agreements, rgely a matter of chance. The owner has, to be sure, a choice of designs, but

*The American Institute of Architects, Document 114. Reprinted by permission. horized by the 43d annual convention at Washington, D. C., December 14-16, 1909; ed March 30, 1910, amended June 10, 1910; and January 3, 1911; ratified by the annual convention at San Francisco, January 16-21, 1911; reaffirmed by the 45th ual convention at Washington, D. C.; amended January 3, 1912, as authorized by convention; amended December 9, 1912, and ratified by the 46th annual convention Vashington, D. C., December 10-12, 1912; amended December 2, 1913, and ratified the 47th annual convention at New Orleans, La., December 3-5, 1913; amended and ied by the 48th annual convention at Washington, D. C., December 2-4, 1914.

he is no more likely to make the wisest selection or to obtain the best buil-
than if he selects his architect directly, guided by the results previously achi-
by the men he is considering. When a competition is necessary or desir-
it should be of such form as to establish equitable relations between the ow-
and the competitors. To insure this:

(1) The REQUIREMENTS should be clear and definite, and the statement of
them, since it must be in technical terms, should be drawn by one familiar wi-
such terms.

(2) The COMPETENCY of all competing should be assured. The drawings sub-
mitted in a competition are evidence, only in part, of the ability of the archit-
to execute the building. The owner, for his own protection, should admit to
the competition only those to whom he would be willing to entrust the wo-
that is, to men of known honesty and competence.

(3) The AGREEMENT between the owner and the competitors should be
definite, as becomes a plain statement of business relations.

(4) The JUDGMENT should be based on knowledge, and since ideas present-
in the form of drawings are intelligible only to a trained mind, judgment sho-
not be rendered until the owner has received competent technical advice as to
the merits of those ideas.

To sum up: To insure the best results, a competition should have (1) a clea-
programme, (2) competent competitors, (3) a business agreement, (4) a fa-
judgment.

Fifteen years ago many competitions had none of these provisions and fe-
had all of them. The commonest form of competition was one that wa-
open to all, had a programme prepared by a layman, was judged by the owne-
without professional assistance, contained no agreement, and made no provisi-
to eliminate the incompetent. All this demanded correction. The Institute,
seeking a means of reform, perceived at once that its relation to the owner cou-
be only an ADVISORY one. It might advise him how to hold a competition,
but it could go no further. To architects in general the Institute cou-
scarcely presume to offer even its advice, but being a professional bod-
charged with maintaining ethical standards among its own members, its du-
was to see that they did not take part in competitions that fell below a reaso-
able standard.

It was, therefore, voted in convention of the Institute that members sho-
be free to take part in competitions only when their terms had received th-
APPROVAL OF THE INSTITUTE. Thereupon the Institute fully stated the prin-
ciples which should govern competitions and defined the conditions prerequisi-
to the giving of its approval. These are contained in the CIRCULAR OF ADVI-
here following, which is intended as a guide to all who are interested in com-
petitions. Committees of the Institute throughout the country are authoriz-
to give its approval to competitions when properly conducted, but unless t-
programme has received such approval members of the Institute do not accep-
a position as competitor or juror, nor does a member continue to act as profe-
sional adviser after it becomes evident that the owner will not permit hi-
programme to be brought into harmony with the principles approved by th-
Institute.

The position thus taken by the Institute is by no means an arbitrary one, si-
it governs the action of none but its own members. To the owner its servi-
has been of great value in giving him information and useful advice and in savi-
him from the delays, cost and disappointment incident to the amateur cond-
of a competition. The owner who disregards the standard set by the Instit-
finds it increasingly difficult to get men of standing in the profession to ent-
He who raises his programme to that standard has no difficulty in securing th-

vices of architects of the greatest ability. Even in the few years since the titute first made its firm stand against the abuses of competitions, the effect that action has been far greater than could have been foreseen. It has not agether eliminated ill-regulated competitions, but it has greatly reduced their nber, and it is safe to say that no competition of prime importance is now ducted except in accordance with the principles stated in the following CIR-LAR OF ADVICE:

Circular of Advice and Information Relative to the Conduct of Architectural Competitions

Competitions are instituted to enable the OWNER * to choose an ARCHITECT ough comparison of the designs submitted. The American Institute of Archi-ts, believing that the interests of both owner and competitors are best served fair and equitable agreements between them, issues this circular as a STATE-NT OF THE PRINCIPLES which should underlie such agreements. The Institute s not assume to dictate the owner's course in conducting competitions, but s to assist him by advising the adoption of such methods as experience has ved to be just and wise. So important, however, does the adoption of such thods appear to architects that members of the Institute do not take part in npetitions except under conditions based on this circular and specifically set h in Articles (16) and (18).

1) **On Competitions in General.** A competition exists when two or more itects prepare sketches at the same time for the same project, but no archi- who prepares drawings for comparison in problems of an altruistic or edu-onal nature, where the problem does not involve a definite proposed building ration, shall be held as having taken part in a competition, within the mean- of this circular of advice.

2) **On the Employment of a Professional Adviser.** No competition l be instituted without the aid of a competent ADVISER. He should be an itect of the highest standing and his selection should be the owner's first . He must be chosen with the greatest care, as the success of the competition depend largely upon his experience and ability. The EXPERT'S ADVICE is reat value to the owner, for example, in so drawing the programme as to guard him against the employment of an architect who submits a design ely exceeding in cost of execution the sum at his disposal, and in helping him void the disappointment, embarrassment and litigation which so often result n competitions conducted without expert technical advice. The DUTIES THE EXPERT are to advise those who hold the competition as to its form and ns, to draw up the programme, to advise in choosing the competitors, to wer their questions, and to conduct the competition.

3) **On the Forms of Competition.** The following forms of competition recognized:

LIMITED. In this form, participation is limited to a certain number of archi-s whose names should be stated in the programme and to any one of whom owner is willing to entrust the work. In a LIMITED COMPETITION the com-itors may be chosen (a) from among architects whose ability is so evident t no formal inquiry into their qualifications is needed, or (b) from among hitects who make application accompanied by evidence of their education experience. The limited form has the advantage that the owner and the fessional adviser may meet competitors and discuss the terms of the com-

* The person, corporation or other entity instituting a competition, whether acting ctly or through representatives, is herein called the OWNER.

petition with them before the issuance of the programme Form (a) is simplest and most direct form of competition.

OPEN. The Institute believes that a competition OPEN TO ALL who wish participate without regard to their qualifications is detrimental to the interests alike of owner and of architects. It will, therefore, give its approval to that form only when conducted in two stages, since by that means alone it is possible to insure anonymity of submission while safeguarding the owner's interests against the selection as winner of a person lacking the qualifications set forth in Article (4) hereof. In this form there is a FIRST STAGE open to all, in which the competitive drawings are of the slightest nature, involving only the fundamental ideas of the solution. These drawings are accompanied by evidence of the competitor's education and experience. From the first stage a small number who have thus demonstrated their competence to design the work and to carry it successfully into execution are chosen to take part in A FINAL and strictly ANONYMOUS STAGE involving competitive drawings of the type indicated in Article hereof.

(4) **On the Qualification of Competitors.** The interests of the owner may be seriously prejudiced by admitting to a limited competition or to the second stage of an open competition any architect who has not established to the satisfaction of the owner his competence to design and execute the work. It is sometimes urged that by admitting all who wish to take part some unknown but brilliant designer may be found. If the object of a competition were a set of sketches, such reasoning might be valid. But sketches give no evidence that their author has the matured artistic ability to fulfil their promise, or that he has the technical knowledge necessary to control the design of the highly complex structure and equipment of a modern building, or that he has executive ability for large affairs, or the force to compel the proper execution of contracts. Attempts have often been made to defend the owner's interests by associating an architect of ability with one lacking in experience. These have generally resulted in failure. As the owner should feel bound, not only legally, but in point of honor, to retain as his architect the competitor to whom the award is made, it is essential that the competitors in a limited competition, or in the second stage of an open competition, should be selected with the greatest care in consultation with the professional adviser, and that there should be included among them only architects in whose ability and integrity the owner has absolute confidence, and to any one of whom he is willing to entrust the work.

(5) **On the Number of Competitors.** Experience has demonstrated that the admission of MANY COMPETITORS is detrimental to the success of a competition. When there are many, each knows that he has but a slight chance of success, and he is therefore less aroused to his best effort than when there are a few. As the owner is interested only in the best result, he is ill-advised to sacrifice quality for quantity.

(6) **On Anonymity of Competitors.** Absolute and effective ANONYMITY is a necessary condition of a fair and unbiased competition. The SIGNING OF DRAWINGS should not be permitted nor should they bear any motto, device or distinguishing mark. Drawings and the accompanying sealed envelopes containing their authors' names should be numbered upon receipt, the envelopes remaining unopened until after the award.

(7) **On the Cost of the Proposed Work.** No statement of the intended COST OF THE WORK should be made unless it has been ascertained that the work as described in the programme can be properly executed within the sum named. In ge[illegible] wiser to limit the cubic contents of the building than to state

t of cost. The programme should neither require nor permit competitors urnish their own or builders' estimates of the cost of executing the work in ordance with their designs. Such estimates are singularly unreliable. If cubage be properly limited they are unnecessary.

8) **On the Jury of Award.** To insure a wise and just award and to pro- the interests of both the owner and the competitors, the competitive draw- should be submitted to a JURY so chosen as to secure expert knowledge and dom from personal bias. Such a jury thoroughly understands and can lain the intent of the drawings. It discovers from them their authors' l in design, arrangement and construction. Because of its trained judgment advice as to the merits of the designs submitted is of the highest value to the ner. The jury must consist of at least three members, one of whom must, a majority of whom should, be PRACTICING ARCHITECTS. One or more mbers of the jury may be chosen by the competitors. It is the DUTY OF THE Y to study carefully the programme and all conditions relating to the problem the competition before examining the designs submitted; to refuse to make ecommend an award in favor of the author of any design that does not fulfil conditions distinctly stated as mandatory in the programme; to give ample e to the careful study of the designs; and to render a decision only after ure consideration. The jury should see to it that a copy of its report reaches ry competitor. The professional adviser should not be a member of the , as his judgment is apt to be influenced by his previous study of the problem.

9) **On the Competitive Drawings.** The purpose of an architectural com- tion is not to secure fully developed plans, but such evidence of skill in treat- the essential elements of the problem as will assist in the SELECTION OF AN HITECT. The drawings should, therefore, be as few in number and as simple haracter as will express the general design of the building. A jury of experts s not need elaborate drawings.

10) **On the Programme.** The programme should contain rules for the duct of the competition, instructions for competitors and the jury, and the ement between the owner and the competitors. Uniform conditions for all petitors are fundamental to the proper conduct of competitions. Lengthy grammes and detailed instructions as to the desired accommodations should avoided as they confuse the problem and hamper the competitors. The blem should be stated broadly. Its solutions should be left to the competi- . A distinction should be clearly drawn between the MANDATORY and the ISORY provisions of the programme, that is, between those which, if not met, clude an award in favor of the author of a design so failing, and those which merely optional or of a suggestive character. The mandatory requirements uld be set forth in such a way that they cannot fail to be recognized as such. y should be as few as possible, and should relate only to matters which not be left to the discretion of the competitors. It is difficult to summarize fly the programme, but it should at least:

a) Name the owner of the structure forming the subject of the competition, l state whether the owner institutes the competition personally or through resentatives; if the latter, name the representatives, state how their author- is derived, and define its scope.

b) State the kind of competition to be instituted, and in limited competitions ne the competitors; or in open competitions, if the competition is limited graphically or otherwise, state the limits.

c) Fix a time and place for the receipt of the designs. The time should not altered except with the unanimous consent of the competitors.

d) Furnish exact information as to the site.

(e) State the desired accommodation, avoiding detail.
(f) State the cost if it be fixed or, better, limit the cubic contents.
(g) Fix uniform requirements for the drawings, giving the number, the s or scales, and the method of rendering.
(h) Forbid the submission of more than one design by any one competito
(i) Provide a method for insuring anonymity of submission.
(j) Name the members of the jury or provide for their selection. De their powers and duties. If for legal reasons the jury may not make the award, state such reasons and in whom such power is vested.
(k) Provide that no award shall be made in favor of any design until the j shall have certified that it does not violate any mandatory requirement of programme.
(l) Provide that during the competition there shall be no communicati relative to it between any competitor and the owner, his representatives, or member of the jury, and that any communication with the professional advi shall be in writing. Provide also that any information, whether in answer such communications or not, shall be given in writing simultaneously to competitors. Set a date after which no questions will be answered.
(m) State the number and amount of payments to competitors.
(n) Provide that the professional adviser shall send a report of the compe tion to each competitor, including therein the report of the jury.
(o) Provide that no drawing shall be exhibited or made public until after award of the jury.
(p) Provide for the return of unsuccessful drawings to their respective auth within a reasonable time.
(q) Provide that nothing original in any of the unsuccessful designs shall used without consent of, and compensation to, the author of the design in wh it appears.
(r) Include the contract between the owner and the competitors.
(s) Include the contract between the owner and the architect receiving award.

(11) **On the Agreement.** An owner who institutes a competition assu a moral obligation to retain one of the competitors as his architect. In o that architects invited to compete may determine whether they will take p it is essential that they should know the terms upon which the winner wil employed; and it is of the utmost importance to the owner that those te should be so clearly defined that no disagreement as to their meaning can after the award is made. Unless they be so defined, delay is likely to occur disagreements to arise at a time when a complete understanding between ow and architect is most important for the welfare of the work. Therefore, th must be included in the programme a form which guarantees the appointm of one of the competitors as architect and provides an agreement operat upon that appointment, defining his employment in terms consonant with best practice. This must conform in all fundamental respects to the ty form of agreement appended to this circular.

(12) **On Payments to Unsuccessful Competitors.** In a limited co petition and in the second stage of an open competition each competit except the winner, should be paid for his services.

(13) **On Legality of Procedure.** It is highly important that each s taken in connection with a competition and every provision of the progra should be in consonance with law. Those charged with holding the competit should know and state their authority. If they are not empowered to bind th principal by contracts with the competitors, they should seek and receive

authority before issuing an invitation. If authority cannot legally be granted to the jury to make the award, that fact should be stated, and the body named in which such authority is vested.

(14) **On the Conduct of the Owner.** In order to maintain absolute impartiality toward all competitors, the owner, his representatives and all connected with the enterprise should, as soon as a professional adviser has been appointed, refrain from holding any communication in regard to the matter with any architect except the adviser or the jurors. The meeting with competitors described in Article (3) is of course an exception.

(15) **On the Conduct of Architects.** An architect should not attempt in any way, except as a duly authorized competitor, to secure work for which a competition is in progress, nor should he attempt to influence, either directly or indirectly, the award in a competition in which he is a competitor. An architect should not accept the commission to do the work for which a competition has been instituted if he has acted in an advisory capacity, either in drawing the programme or making the award. An architect should not submit in competition a design which has not been produced in his own office or under his own direction. No competitor should enter into association with another architect, except with the consent of the owner. If such associates should win the competition, their association should continue until the completion of the work thus won. During the competition, no competitor should hold any communication relative to it with the owner, his representatives or any member of the jury, nor should he hold any communication with the professional adviser, except it be in writing. When an architect has been authorized to submit sketches for a given project, no other architect should submit sketches for it until the owner has taken definite action on the first sketches, since, as far as the second architect is concerned, a competition is thus established.

(16) **On the Participation of Members of the Institute.** Members of The American Institute of Architects do not take part as competitors or jurors in any competition the programme of which has not received the formal approval of the Institute, nor does a member continue to act as professional adviser after it has been determined that the programme cannot be so drawn as to receive such approval.

(17) **Committees.** In order that the advice of the Institute may be given to those who seek it and that its approval may be given to programmes in consonance with its principles, the Institute maintains the following committees:

(a) The STANDING COMMITTEE ON COMPETITIONS, representing the Institute in its relation to competitions generally. This committee advises the subcommittees and directs their work and they report to it.

(b) A SUBCOMMITTEE for the territory of each chapter, representing the Institute in its relation to competitions for work to be erected within such territory.

The president of the chapter is EX-OFFICIO chairman of the subcommittee, the other members of which he appoints. The subcommittees derive their authority from the Institute and not from the chapters. An appeal from the decision of a subcommittee may be made to the standing committee. The standing committee may approve, modify or annul the decision of a subcommittee.

(18) **The Institute's Approval of the Programme.** The approval of the Institute is not given to a programme unless it meets the following essential conditions:

(a) That there be a professional adviser.

(b) That the competition be of one of the forms described in Article (3).

(c) That the programme contain an Agreement and Conditions of Contract between architect and owner in conformity with those printed in the Appendix of this circular, that it include no provision at variance therewith, that it contain terms of payments in accord with good practice, and that it specifically set forth the nature of expert engineering services for which the architect will be reimbursed.

(d) That the programme make provision for a jury of at least three persons.

(e) That the programme conform in all particulars to the spirit of this circular.

When the programme meets the above essential conditions, the approval of the Institute may be given to it by the subcommittee for the territory in which the work is to be erected, or if there be no subcommittee for that territory, then by the standing committee on competitions. If, for legal or other reasons, the standing committee deem that deviations from the essential conditions are justified, it may give the approval of the Institute to a programme containing such deviations. Power to give approval in such cases is, however, vested only in the standing committee. The professional adviser, when duly authorized in writing by the proper committee, may print the Institute's approval as a part of the programme or otherwise communicate it to those invited to compete.

Typical Form of Agreement between Owner and Competitors

In consideration of the submission of drawings in this competition (here insert the name of the owner or of the body duly authorized to enter into contract on behalf of the owner), hereinafter called the Owner, agrees with the competitors jointly and severally that the owner will, within .... days of the date set for the submission of drawings, make an award of the commission to design and supervise the work forming the subject of this competition to one of those competitors who submit drawings in consonance with the mandatory requirements of this programme, and will thereupon pay him, on account of his services as architect, one-tenth of his total estimated fee as stated below. And further in consideration of the submission of drawings as aforesaid and the mutual promises enumerated in the subjoined Conditions of Contract between Architect and Owner, the owner agrees and each competitor agrees, if the award be made in his favor, immediately to enter into a contract containing the Conditions here following, and until such contract is executed to be bound by the said Conditions.

Conditions of Contract between Architect and Owner

Article I. Duties of the Architect

(1) **Design.** The architect is to design the entire building and its immediate surroundings and is to design or direct the design of its constructive, engineering and decorative work and its fixed equipment and, if further retained, its movable furniture and the treatment of the remainder of its grounds.

(2) **Drawings and Specifications.** The architect is to make such revision of his competitive scheme as may be necessary to complete the preliminary studies; and he is to provide drawings and specifications necessary for the conduct of the work. All such instruments of service are and remain the property of the architect.

(3) **Administration.** The architect is to prepare or advise as to all forms connected with the making of proposals and contracts, to issue all certificates

payment, to keep proper accounts and generally to discharge the necessary lministrative duties connected with the work.

(4) **Supervision.** The architect is to supervise the execution of all the work mmitted to his control.

ARTICLE II. DUTIES OF THE OWNER

(1) **Payments.** The owner is to pay the architect for his services a sum jual to .... per cent * upon the cost of the work. (The times and amounts payments should be here stated.) †

(2) **Reimbursements.** The owner is to reimburse the architect, from time time, the amount of expenses necessarily incurred by him or his deputies ile traveling in the discharge of duties connected with the work.

(3) **Service of Engineers.** The owner is to reimburse the architect the cost the services of such engineers for heating, mechanical and electrical work as e specifically provided for in each programme. The selection of such engineers d their compensation shall be subject to the approval of the owner.

(4) **Information, Clerk of the Works, etc.** The owner is to give all inrmation as to his requirements; to pay for all necessary surveys, borings and ts, and for the continuous services of a clerk of the works, whose competence approved by the architect.

Standard Form of Competition-Programme ‡

The following standard form of COMPETITION-PROGRAMME, prepared by The nerican Institute of Architects, contains those provisions which the Institute nsiders essential to the fair and equitable conduct of a competition. The stitute in no way assumes or attempts to dictate an OWNER's course in conicting a competition; it claims only the right to control its own members, and ving found by experience the danger to the interests of both OWNER and MPETITOR from a competition in which such provisions are lacking, it perits no member to take part in any competition which does not meet those ential conditions, and the programme of which has not been specifically proved. A competition should be of such form as to establish equitable relans between the OWNER and the COMPETITOR. To insure this, the requirents should be clear and definite; the competency of the COMPETITORS should assured; the agreement between the OWNER and COMPETITORS should be finite, as becomes a plain statement of business relations; and the judgment ould be based on expert knowledge. The following programme will, if adhered be duly approved by the Institute SUBCOMMITTEES ON COMPETITIONS for e various chapters of the Institute, and by the STANDING COMMITTEE ON MPETITIONS of the Institute.

* The percentage inserted should be in accord with good practice.

† Good practice has established the payments on account as follows: Upon completion the preliminary studies one-fifth of the total estimated fee less the previous payment; n completion of contract-drawings and specifications two-fifths additional of such fee; other drawings, for supervision and for administration, the remainder of the fee, n time to time, in proportion to the progress of the work.

‡ As authorized by the 48th annual convention, 1914. The American Institute of hitects, Document, Series A, No. 115, Washington, D. C., January, 1918. Reprinted permission.

Programme of Competition for

....

(Insert name of proposed building)

NOTE. Throughout this programme the word OWNER is used to indicate either the owner in person, or those to whom he has delegated his powers.

PART I

(1) **Proposed Building.** The..

(Insert name of owner)

proposes to erect a new..

(Insert name of building)

on the site at..

(Insert location)

(2) **Authority.** The..

(Insert name of owner)

has (delegated to..

(Insert name or names of individuals)

authority to select an ARCHITECT to prepare the plans for, and supervise the erection of the building.

NOTE. If authority for the erection of the proposed building is granted by act of legislature, ordinance, etc., it is desirable to make clear the source of such authority.

(3) **Architectural Adviser.** The OWNER has appointed as his expert PROFESSIONAL ADVISER..

(Insert name and address of adviser)

to prepare this programme and to act as his ADVISER in the conduct of this competition.

NOTE. No competition shall be instituted without the aid of a competent adviser. He should be an architect of the highest standing and his selection should be the Owner's first step. He should be chosen with the greatest care, as the success of the competition will depend largely upon his experience and ability. The duties of the expert are to advise those who hold the competition in regard to its form and terms, to draw up the programme, to advise in choosing the COMPETITORS, to answer inquiries from COMPETITORS and in general to direct the competition.

(4) **Competitors.** Participation in this competition is limited (A), to the following ARCHITECTS:..

(Insert names of invited competitors)

or
and (B) To such ARCHITECTS as shall have made application on or before.....

....

(Insert date)

accompanied by evidence of their education and experience, satisfactory to the OWNER and the PROFESSIONAL ADVISER. It is agreed that the names of all those admitted to the competition shall be made public on or before..........

....

(Insert date)

The OWNER agrees that he will admit no one as a COMPETITOR to whom he is not willing to award the commission to erect the building, in case of his success in the competition.

(5) **Jury of Award.** The Owner agrees that there will be a Jury of Award
l) which will consist of the following members:.........................
....
(Insert names of jury)

r (B) which will consist of..............members. Of these, the Owner
(Insert number)

s appointed the following:...
....and
(Insert names of those so selected)

e Competitors will select the remaining members of the Jury.

NOTE. To insure a just and wise award and to protect the interests of both the wner and the Competitors, the drawings should be submitted to a Jury chosen to cure expert knowledge and freedom from personal bias. The Jury shall consist of at ist three members, one of whom must, and the majority of whom should, be practicing chitects, for example, a layman and an architect selected by the Owner or the Building mmittee, and an architect selected by the Competitors. For work of great imporace it is desirable to increase the size of the Jury, adding to it architects and specially alified laymen. Some of the advantages of a Jury so constituted are that it thoroughly iderstands and can explain the intent of the drawings, and discovers from them their thor's skill in design, arrangement and construction. Because of its expert knowledge, judgment on the merits of the designs submitted is of the highest value to the Owner. e adoption of the recommendation that the architectural members of the Jury be in e majority, is not necessarily a cause of expense, for the reason that in order to insure e proper conduct of competitions, many architects of standing are willing, if the occasion irrants, to serve as Jurors without payment, other than actual expenses. It is cusmary and desirable that the Competitors should elect one or more of the architectural embers of the Jury. It is not advisable that the Professional Adviser, who has awn up the programme, be permitted to vote as a member of the Jury, although he ay with advantage take part in the deliberations of the Jury.

(6) **Authority of Jury.** The Owner agrees that the Jury above named, or lected as above provided, will have authority to make the award and that its cision in the matter shall be final. Moreover, this Jury will make an award one of those taking part in this competition, unless no design is submitted iich fulfils the mandatory requirements of this programme. The Owner rther agrees to employ as architect for the work as more fully set forth hereiner, the author of the design selected by the Jury as its first choice.

NOTE. If, under the law, authority to make the award cannot be delegated to the ry, the following form should be substituted for Section (6):

The Owner agrees that the Jury above named or selected as above provided, will ect the design which appears to it to be the most meritorious and make a written report the Owner, designating it by number. The Owner will then consider this design the report of the Jury and will thereupon, without learning the identity of the Comitors, select as the winner of the competition the author of the design selected by Jury, unless in his judgment there be cause to depart from such selection, in which e he will, still without learning the identity of the Competitors, select one of the other igns submitted in competition. The Owner further agrees that he will pay to the thor of the design designated as most meritorious by the Jury, in case he should not appointed Architect of the building, a prize of $.................................
(State amount of prize)

The opening of the envelope containing the name of the author of the design selected the Owner will automatically close the contract between him and the Owner, printed Part III hereof.

(7) **Examination of Designs and Award.** The Professional Adviser will amine the designs to ascertain whether they comply with the mandatory re-

quirements of the programme, and will report to the JURY any instance of failure to comply with these mandatory requirements. The OWNER further agrees that the JURY will satisfy itself of the accuracy of the report of the PROFESSIONAL ADVISER, and will place out of competition and make no award to any design which does not comply with these mandatory requirements. The JURY will carefully study the programme and any modifications thereof, which may have been made through communications (see Section (12)), and will then consider the remaining designs, holding at least two sessions on separate days, and considering at each session all the drawings in competition, and will make the award and the classification of prize-winners, if prizes are given, by secret ballot, and by majority vote, before opening the envelopes which contain the names of the COMPETITORS. In making the award the JURY will thereby affirm that it has made no effort to learn the identity of the various COMPETITORS, and that it has remained in ignorance of such identity until after the award was made. The opening of the envelope containing the name of the author of the selected design will automatically close the contract between him and the OWNER, printed as Part III hereof.

(8) **Report of the Jury.** The JURY will make a full report which will state its reasons for the selection of the winning design and its reason for the classification of the designs placed next in order of merit, and a copy of this report, accompanied by the names of prize-winners, if prizes are given, will be sent by the PROFESSIONAL ADVISER to each COMPETITOR. Immediately upon the opening of the envelopes, the PROFESSIONAL ADVISER will notify all COMPETITORS, by wire, of the result of the competition.

(9) **Compensation to Competitors.** The OWNER agrees to pay to the successful COMPETITOR within ten days of the judgment, on account of his fee for services as ARCHITECT, one-tenth of his total estimated fee.

In full discharge of his obligation to them (in case prizes or fees are offered), the OWNER agrees:

(A) To pay the following prizes to those ranked by the JURY next to the successful design: To the design placed second $........, to the design placed third $........, to the design placed fourth $........, to the design placed fifth $........., etc., within ten days of the judgment, or

(B) To pay to each of the COMPETITORS invited to take part in this competition, other than the successful COMPETITOR, a fee of $........ within ten days of the judgment.

(10) **Exhibition of Drawings.** It is agreed that no drawings shall be exhibited or made public until after the award of the JURY. There will be a public exhibition of all drawings after the judgment, and all drawings, except that of the successful COMPETITOR, will be returned to their authors at the close thereof.

(11) **Use of Features of Unsuccessful Designs.** Nothing original in the unsuccessful designs shall be used without consent of, or compensation to, the author of the design in which it appears. In case the OWNER desires to make use of any individual feature of an unsuccessful design, the same may be obtained by adequate compensation to the designer, the amount of such compensation to be determined in consultation with the author and the PROFESSIONAL ADVISER.

(12) **Communications. (Mandatory.)** If any COMPETITOR desires information of any kind whatever in regard to the competitition, or the programme, he shall ask for this information by anonymous letter addressed to the PROFESSIONAL ADVISER, and in no other way, and a copy of this letter and the

answer thereto will be sent simultaneously to each COMPETITOR, but no request received after ....

(Insert date)

will be answered.

(13) **Anonymity of Drawings. (Mandatory.)** The drawings to be submitted shall bear no name or mark which could serve as a means of identification, nor shall any such name or mark appear upon the wrapper of the drawings, nor shall any COMPETITOR directly or indirectly reveal the identity of his designs, or hold communication regarding the competition with the OWNER or with any member of the BUILDING COMMITTEE or of the JURY, or with the PROFESSIONAL ADVISER, except as provided for under COMMUNICATIONS. It is understood that in submitting a design, each COMPETITOR thereby affirms that he has complied with the foregoing provisions in regard to anonymity and agrees that any violation of them renders null and void this agreement and any agreement arising from it. With each set of drawings must be enclosed a plain, opaque, sealed envelope without any superscription or mark of any kind, same containing the name and address of the COMPETITOR. These envelopes shall be opened by the PROFESSIONAL ADVISER after the final selection has been made, and preferably in the presence of the JURY.

(14) **Delivery of Drawings. (Mandatory.)** The drawings submitted in this competition shall be securely wrapped, addressed to the PROFESSIONAL ADVISER at ....
.... in plain lettering and

(Insert address for delivery of drawings)

with no other lettering thereon, and delivered at this address not later than
....

(Insert date and hour)

In case drawings are sent by express, they may be delivered to an express company at the above date and hour, in which case the express company's receipt, bearing date and hour, shall be mailed immediately to the PROFESSIONAL ADVISER as evidence of delivery.

PART II

(15) **Site.** The site of the building is as follows....................

(Insert description of site, and provide topographical map giving dimensions, grades, etc.)

NOTE. The site should be carefully described and a survey of the property should be attached and included as part of the programme. Conditions pertaining to the site and to neighboring buildings frequently become determining factors in a design. Photographs showing surrounding buildings and landscape-conditions may with advantage be included.

(16) **Cost. (Mandatory.)** For the purpose of this competition the cost of the building shall be figured at.........cts per cu ft, and the total thereof

(Insert number)

figured on this basis shall not exceed ....

(Insert limit of cost)

(17) **Cubage. (Mandatory.)** Cubage shall be so computed as to show as exactly as possible the actual volume of the building, calculated from the finished level or levels of the lowest floor to the highest points of the roofs, and contained within the outside surfaces of the walls. Pilasters, cornices, balconies and other similar projections shall not be included. Porticos with engaged columns and similar projections shall be taken as solids and figured to the outer face of the columns. When columns are free-standing, one-half of the volume of the porti-

cos shall be taken. There shall also be included in the cubage the actual volume of all parapets, towers, lanterns, dormers, vaults, and other features adding to the bulk of the building, also the actual volume of exterior steps above grade. Light-wells of an area of less than 400 sq ft shall not be deducted. In calculating cubage, account shall be taken of variations in the exterior wall-surface, as for example, the projection of a basement-story beyond the general line of the building. A figured diagram showing method adopted in cubing shall accompany each set of drawings.

(18) **Drawings.** **(Mandatory.)** The drawings submitted shall be made according to the following list, at the scale given, and rendered as noted; and no other drawings than these shall be submitted:

....

(Insert list, scale and method of rendering)

NOTE. The drawings submitted should be the least number necessary to set forth clearly the solution of the problem, and the scale of these drawings the smallest compatible with the requirement that the intention of each COMPETITOR be made clear to an expert JURY. Where the number and scale of drawings is reduced to the minimum, and simple methods of rendering imposed, the COMPETITORS are enabled to devote their time and energy to the study of the problem, which is the serious business of a competition, instead of upon draughtsmanship and rendering, which when carried beyond a certain point, are of no value whatever in determining the fitness of the COMPETITORS to handle the work of erecting the building, for which the competition is being held.

PART III

Agreement between Owner and Competitors

In consideration of the submission of drawings in this competition, and the mutual promises enumerated in the subjoined CONDITIONS OF CONTRACT BETWEEN ARCHITECT AND OWNER the OWNER agrees, and each COMPETITOR agrees if the award be made in his favor, immediately to enter into a contract containing all the CONDITIONS here following, and until such contract is executed, to be bound by the said CONDITIONS.

Conditions of Contract between Architect and Owner

Duties of the Architect

(1) **Design.** The ARCHITECT is to design the entire building and its immediate surroundings and is to design or direct the design of its constructive, engineering and decorative work and its fixed equipment and, if further retained, its movable furniture and the treatment of the remainder of its grounds.

(2) **Drawings and Specifications.** The ARCHITECT is to make such revision of his competitive scheme as may be necessary to complete the preliminary studies; and he is to provide drawings and specifications necessary for the conduct of the work. All such instruments of service are and remain the property of the ARCHITECT.

(3) **Administration.** The ARCHITECT is to prepare or advise as to all forms connected with the making of proposals and contracts, to issue all certificates of payment, to keep proper accounts and generally to discharge the necessary administrative duties connected with the work.

(4) **Supervision.** The ARCHITECT is to supervise the execution of all the work committed to his control.

Duties of the Owner

(5) **Payments.** The OWNER is to pay the ARCHITECT for his services a um equal to........per cent upon the cost of the work.

NOTE. The percentage inserted should be in accord with good practice. The times d amounts of payments should be here stated. Good practice has established the yments on account as follows: Upon completion of the preliminary studies one-fifth the total estimated fee less the previous payment; upon completion of contract-drawings d specifications two-fifths additional of such fee; for other drawings, for supervision d for administration, the remainder of the fee, from time to time, as the work progresses.

(6) **Reimbursements.** The OWNER is to reimburse the architect from time time, the amount of expenses necessarily incurred by him or his deputies hile traveling in the discharge of duties connected with the work.

(7) **Service of Engineers.** The OWNER is to reimburse the ARCHITECT, e cost of the services of ENGINEERS for...
nsert nature of work for which the OWNER agrees that ENGINEERS shall be employed at s expense)

The selection of such ENGINEERS and their compensation shall be subject to e approval of the OWNER.

(8) **Information, Clerk of the Works, Etc.** The OWNER is to give all in- rmation as to his requirements; to pay for all necessary surveys, borings and sts, and for the continuous services of a clerk of the works whose competence approved by the ARCHITECT.

PART IV

Requirements of the Building

NOTE. For the same reason that elaborate drawings are undesirable, it is advisable avoid lengthy and detailed instructions as to the desired accommodations, as they nfuse the problem and hamper the COMPETITORS; and the OWNER loses thereby the nefit he might gain in allowing the COMPETITORS freedom to develop solutions which ey would not otherwise be at liberty to suggest. It should be borne in mind that either e cost of the building, as determined by its cubical contents, should be fixed, or the quirements of the OWNER in regard to the design, materials of construction, dimensions rooms, etc., should be fixed, but not both. If, on the one hand, the cubical contents d cost is fixed, it should be stated that the requirements of the OWNER must be adhered as closely as possible by COMPETITORS; if, on the other hand, the requirements of the WNER are definitely fixed, it may be stated that the cubical contents of each design, hile not limited, will be taken into consideration in making the award. In case the es of certain rooms, etc., are definitely fixed, the word MANDATORY should be placed the head of the paragraph referring to these rooms.

Here should follow a list of rooms required, together with sizes and other data hich apply to the building under consideration.

THE STANDARD DOCUMENTS OF THE AMERICAN INSTITUTE OF ARCHITECTS*

Introductory Notes. This introductory paragraph is from an article† by Clipston Sturgis, President of The American Institute of Architects. "For many years builders and owners have commonly used an agreement recognized as inadequate and imperfect, and one apt to lead to serious misunderstandings, if not to legal difficulties. Architects entrusted with important work and its accompanying responsibilities have endeavored to have agreements drawn which would adequately safeguard the interests involved. When, some nine years ago (1906), the Institute attempted to prepare a new standard agreement, it found already in use a considerable number of forms prepared by architects, differing in detail but agreeing in one main point. This one point was that the contract and the conditions of the contract should be treated as two branches of the same agreement, not as one document, nor yet as two. The contract was to be as brief as possible, stating simply what the obligation was. The conditions of the contract, complicated and involved, yet essential to the contract, were of necessity comparatively lengthy. The most difficult part of the work, surveying the field and breaking out the way, was done by the Committees on Contracts and Specifications during the years 1906 to 1911, and resulted in the first edition of the STANDARD DOCUMENTS, published in 1911. At that time some thought the problem solved; others thought it but an important step forward; which latter proved to be the fact. These first documents, excellent as they were as text-books, were not suitable for everyday use. The Institute again took up the problem, this time with the definite aim to produce a document which should entirely replace the uniform agreement when the contract for its publication expired in May 1915. This has been done and the carefully studied AGREEMENT and CONDITIONS OF THE CONTRACT presented to the convention in December, 1914, have been further studied and improved and are now (1915) on the market for general use. In the final study between January and May, 1915, the Institute had the advantages of coöperation with representatives of many of the building trades and the advice of counsel representing the Institute and counsel representing the building trades. The document, like its predecessor, will now come to the test of actual use. It will prove to be imperfect and revised sections will be necessary, but it is believed to be in the main a fair and comprehensive agreement and one that is practical and fit for general use. Architects everywhere are urged to use and test this form, and criticism from owners and builders will be gladly received and considered. In addition to this most important document the committee has prepared and the Institute has published a form of BOND, a LETTER OF ACCEPTANCE by a contractor of a sub-contractor's bid, and an AGREEMENT between a contractor and sub-contractor. Many architects who have done work on which a bond has been required have been surprised at the ease with which the obligations of the bond could be evaded. In most cases, because someone, architect, contractor, or owner, had invalidated the bond. The new form of bond is prepared for insuring, as far as possible, that the bonding company shall discharge its obligations and protect the owner who pays for this protection. The LETTER FROM CONTRACTOR TO SUB-CONTRACTOR is intended to provide a simple form whereby the mutual obligations of the two shall be clearly defined. The AGREEMENT BETWEEN CONTRACTOR AND SUB-CONTRACTOR accomplishes the same purpose in a somewhat more formal way."

* Third Edition, copyrighted by The American Institute of Architects, 1915–1918, and inserted here by permission.

† Published in the Journal of The American Institute of Architects, June, 1915.

The Development of the Standard Documents. In the year 1887 The merican Institute of Architects, the Western Association of Architects and the ational Association of Builders, thinking it desirable to establish better practice the matter of building contracts, undertook the preparation of a form of conact satisfactory to all. Under the name of THE UNIFORM CONTRACT this form tained wide acceptance and has been long in use. About the year 1907, feeling at practice had advanced to a point no longer fully reflected by the UNIFORM ONTRACT, the Institute undertook a general study of the subject with a view developing a form of contract clear in thought, equitable, applicable to work almost all classes, binding in law and a standard of good practice. The work as entrusted to the Standing Committee on Contracts and Specifications, who ent four years on it, studying the UNIFORM CONTRACT and forms in use by some irty well-known architects, and submitted various drafts for criticism to the apters of the Institute and to engineers, contractors and architects throughout e country. The documents were prepared under the advice of Francis Fisher ane, counsel for the Institute, and Ernest Eidlitz, and with the able and careful iticism of Professor Samuel Williston of the Harvard Law School, and with the sistance of James W. Pryor, in their editing. The Institute gave its approval the work in 1911. The Standing Committee on Contracts and Specifications, uring the preparation of the first edition of the STANDARD FORMS, consisted of rosvenor Atterbury, Chairman; Allen B. Pond, Secretary; Frank Miles Day, illiam A. Boring, Frank C. Baldwin, Frank W. Ferguson, Alfred Stone and . L. Heins. Criticisms of the first edition of the DOCUMENTS were invited by e Institute and during the year 1913 a group of architects and builders in Boson, known as the Joint Committee of the Boston Society of Architects, and of e Master Builders' Association, gave much sincere study to the subject. At e same time the National Association of Builders' Exchange offered a detailed riticism of the documents.

In 1914 the Institute instructed its Standing Committee on Contracts and pecifications to undertake a general revision with a view to making the CONITIONS simpler in wording and more equitable. The committee was empowered hold conferences with organizations so desiring. Subcommittees for the terriory of the several chapters of the Institute were appointed and collaborated with he standing committee. The Boston group presented its ideas in the form of an ntirely new draft which proved of high value and its Chairman, W. Stanley 'arker, was present with the Standing Committee at nearly all its meetings. he Committee had a joint meeting with representatives of the National Assoiation of Builders' Exchanges and thereafter the counsel of the Association, V. B. King, and the counsel of the Institute, Louis Barcroft Runk, collaboated most effectively with the committee. The GENERAL CONDITIONS were ntirely rewritten and in response to the strong desire of contractors and subconractors, the principle of GENERAL ARBITRATION, subject to limitations in the locuments, was adopted, and provisions relative to the RELATIONS OF THE CONRACTOR AND HIS SUBCONTRACTORS were included in the documents. After much tudy, conference and criticism, a draft of the second edition was issued by uthority of the Institute, April 1, 1915. During the revision of the documents, he Standing Committee on Contracts and Specifications consisted of Frank Miles Day, Chairman; Allen B. Pond, Sullivan W. Jones, Clarence A. Martin, Norman M. Isham, Octavius Morgan, Thomas Nolan, A. O. Elzner, M. B. Medary, Jr., Jos. Evans Sperry, Frank W. Ferguson and Samuel Stone.

The Construction of the Standard Documents. An AGREEMENT, and DRAWINGS and SPECIFICATIONS are the necessary parts of a building contract. Many conditions of a general character may be placed at will in the AGREEMENT

or in the SPECIFICATIONS. It is, however, wise to assemble them in a single document and, since they have as much bearing on the DRAWINGS as on the SPECIFICATIONS, and even more on the business relations of the contracting parties, they are properly called the GENERAL CONDITIONS OF THE CONTRACT. As the AGREEMENT, GENERAL CONDITIONS, DRAWINGS and SPECIFICATIONS are the constituent elements of the CONTRACT and are acknowledged as such in the AGREEMENT, they are correctly termed the CONTRACT DOCUMENTS. Statements made in any one of them are just as binding as if made in the AGREEMENT. The Institute's forms, although intended for use in actual practice, should also be regarded as a code of reference representing the judgment of the Institute as to what constitutes good practice and as such they may be drawn upon by architects in improving their own forms. Although the forms are suited for use in connection with a single or general contract, they are equally applicable to an operation conducted under separate contracts.

Titles of the Standard Contract Documents.* The new STANDARD CONTRACT DOCUMENTS of The American Institute of Architects are now on sale† by dealers in office and drafting-supplies in all the large cities of the country, and replace the old UNIFORM CONTRACT. The following are the titles of the STANDARD DOCUMENTS: A. 1. FORM OF AGREEMENT AND A. 2. GENERAL CONDITIONS OF THE CONTRACT. B. BOND OF SURETYSHIP. C. FORM OF SUBCONTRACT. D. LETTER OF ACCEPTANCE OF SUBCONTRACTOR'S PROPOSAL. A cover in heavy paper with valuable EXPLANATORY NOTES is sent without charge with each complete set of the documents. These documents have received the full approval of the Institute, through its conventions, board of directors and officers. They are the outcome of nine years of continuous work by the Standing Committee on Contracts and Specifications. This committee, comprising some of the ablest American architects, was assisted by the Institute's thirty-nine chapters; advised by eminent legal specialists in contract law and aided by representatives of the Building and Trade Associations of the United States. The Standard Documents have received the formal approval of the

† **Notice to Architects, Builders and Contractors.** The CONTRACT FORMS may be obtained singly or in lots from the local dealers. If your dealer cannot supply you send your order and his name to The Executive Secretary, A. I. A., The Octagon, Washington, D. C. All orders must include the necessary remittance irrespective of A. I. A. membership and irrespective of commercial standing of purchaser. The Institute has adopted these CASH TERMS, from which no exception will be made to anybody, in order to reduce cost of accountancy and thereby reduce expense to the user. Remittances may be by check, money-order, cash, or stamps.

Prices for Single Copies: Agreement and General Conditions in cover, \$0.14; General Conditions without Agreement, \$0.10; Agreement without General Conditions, \$0.0[illegible]; Bond of Suretyship, \$0.02; Form of Subcontract, \$0.03; Letter of Acceptance of Subcontractor's Proposal, \$0.02; Cover (heavy paper, with valuable notes), \$0.01; Complete set in cover, \$0.20. A Trial set will be delivered upon receipt of ten 2-cent stamps.

Prices for Quantities and Discounts to Architects, Builders and Contractors. Orders for quantities are subject to the following discounts (which are also given by all dealers):

Five per cent on lots of 100 (one kind or assorted); 10% on lots of 500 (one kind or assorted); 15% on lots of 1 000 (one kind or assorted). As these DOCUMENTS are printed on sheets, 8½ by 11 ins, and in large quantities, they cannot be supplied with any individual names or printing different from the standard forms. The Institute does not wish to encourage the use of the AGREEMENT with general conditions other than those endorsed by it, but on request will sell the AGREEMENTS separate from the STANDARD GENERAL CONDITIONS at 3 cts each.

\rt. 1. Principles and Definitions.

a) The Contract Documents consist of the Agreement, the General Con- ons of the Contract, the Drawings and Specifications, including all modi- tions thereof incorporated in the documents before their execution. These n the Contract.

b) The Owner, the Contractor and the Architect are those named as such in Agreement. They are treated throughout the Contract Documents as if h were of the singular number and masculine gender.

c) The term Subcontractor, as employed herein, includes only those having rect contract with the Contractor and it includes one who furnishes material ked to a special design according to the plans or specifications of this work, does not include one who merely furnishes material not so worked.

d) Written notice shall be deemed to have been duly served if delivered in son to the individual or to a member of the firm or to an officer of the corpora- for whom it is intended, or if delivered at or mailed to the last business ress known to him who gives the notice.

e) The term "work" of the Contractor or Subcontractor includes labor or terials or both.

f) All time-limits stated in the Contract Documents are of the essence of contract.

g) The law of the place of building shall govern the construction of this tract.

\rt. 2. Execution, Correlation and Intent of Documents. The Con- t Documents shall be signed in duplicate by the Owner and Contractor. In of failure to sign the General Conditions, Drawings or Specifications the hitect shall identify them. The Contract Documents are complementary, what is called for by any one shall be as binding as if called for by all. intention of the documents is to include all labor and materials reasonably essary for the proper execution of the work. It is not intended, vever, that materials or work not covered by or properly inferable from any ding, branch, class or trade of the specifications shall be supplied unless inctly so noted on the drawings. Materials or work described in words ch so applied have a well-known technical or trade meaning shall be held efer to such recognized standards.

\rt. 3. Detail Drawings and Instructions. The Architect shall furnish, h reasonable promptness, additional instructions, by means of drawings or erwise, necessary for the proper execution of the work. All such drawings

and instructions shall be consistent with the Contract Documents, true devel-ments thereof, and reasonably inferable therefrom. The work shall be exec in conformity therewith and the Contractor shall do no work without pr drawings and instructions. In giving such additional instructions, the Archi shall have authority to make minor changes in the work, not involving ex costs, and not inconsistent with the purposes of the building. The Contract and the Architect, if either so requests, shall jointly prepare a schedule, subj to change from time to time in accordance with the progress of the wor fixing the latest dates at which the various detail drawings will be requir and the Architect shall furnish them in accordance with that schedule. Und like conditions, a schedule shall be prepared, fixing dates for the submissi of shop drawings, for the beginning of manufacture and installation of materi and for the completion of the various parts of the work.

Art. 4. Copies Furnished. Unless otherwise provided in the Contrac Documents the Architect will furnish to the Contractor, free of charge, a copies of drawings and specifications reasonably necessary for the executio the work.

Art. 5. Shop Drawings. The Contractor shall submit, with such promp ness as to cause no delay in his own work or in that of any other contracto two copies of all shop or setting drawings and schedules required for the wor of the various trades and the Architect shall pass upon them with reasonab promptness. The Contractor shall make any corrections required by th Architect, file with him two corrected copies and furnish such copies as ma be needed. The Architect's approval of such drawings or schedules shall n relieve the Contractor from responsibility for deviations from drawings specifications, unless he has in writing called the Architect's attention to su deviations at the time of submission, nor shall it relieve him from responsibili for errors of any sort in shop drawings or schedules.

Art. 6. Drawings and Specifications on the Work. The Contractor sha keep one copy of all drawings and specifications on the work, in good ord available to the Architect and to his representatives.

Art. 7. Ownership of Drawings and Models. All drawings, specificati and copies thereof furnished by the Architect are his property. They are n to be used on other work and, with the exception of the signed contract s are to be returned to him on request, at the completion of the work. A models are the property of the Owner.

Art. 8. Samples. The Contractor shall furnish for approval all samples directed. The work shall be in strict accordance with approved samples.

Art. 9. The Architect's Status. The Architect shall have general sup vision and direction of the work. He is the agent of the Owner, only to the e tent provided in the Contract Documents and when in special instances he authorized by the Owner so to act, and in such instances he shall, upon reque show the Contractor written authority. He has authority to stop the w whenever such stoppage may be necessary to insure the proper execution of Contract. As the Architect is, in the first instance, the interpreter of Contract and the judge of its performance, he shall side neither with the Ow nor with the Contractor, but shall use his powers under the Contract to enf its faithful performance by both. In case of the termination of the empl ment of the Architect, the Owner shall appoint a capable and reputable Archi whose status under the contract shall be that of the former Architect.

Art. 10. The Architect's Decisions. The Architect shall, within a reas able time, make decisions on all claims of the Owner or Contractor and on

r matters relating to the execution and progress of the work or the interpre-
n of the Contract Documents. The Architect's decisions, in matters relating
tistic effect, shall be final, if within the terms of the Contract Documents.
pt as above or as otherwise expressly provided in these General Conditions
the specifications, all the Architect's decisions are subject to arbitration.

t. 11. **Foreman, Supervision.** The Contractor shall keep on the work a
etent foreman and any necessary assistants, all satisfactory to the
itect. The foreman shall not be changed except with the consent of the
itect, unless the foreman proves to be unsatisfactory to the Contractor
ceases to be in his employ. The foreman shall represent the Contractor
s absence and all directions given to him shall be as binding as if given to
Contractor. Important directions shall be confirmed in writing to the Con-
or. Other directions shall be so confirmed on written request in each
The Contractor shall give efficient supervision to the work, using his best
and attention. He shall carefully study and compare all drawings, specifi-
ns and other instructions and shall at once report to the Architect any error,
sistency, or omission which he may discover.

t. 12. **Materials, Appliances, Employees.** Unless otherwise stipulated,
Contractor shall provide and pay for all materials, labor, water, tools, equip-
, light and power necessary for the execution of the work. Unless other-
specified, all materials shall be new and both workmanship and materials
be of good quality. The Contractor shall, if required, furnish satisfactory
nce as to the kind and quality of materials. The Contractor shall not
oy on the work any unfit person or any one not skilled in the work assigned
m.

t. 13. **Inspection of Work.** The Owner, the Architect and their repre-
tives shall at all times have access to the work wherever it is in preparation
ogress and the Contractor shall provide proper facilities for such access and
spection. If the specifications, the Architect's instructions, laws, ordi-
s or any public authority require any work to be specially tested or
ved, the Contractor shall give the Architect timely notice of its readiness
spection, and if the inspection is by another authority than the Architect,
e date fixed for such inspection. Inspections by the Architect shall be
ptly made. If any such work should be covered up without approval or
nt of the Architect, it must, if required by the Architect, be uncovered
camination at the Contractor's expense. Reexamination of questioned
may be ordered by the Architect. If such work be found in accordance
the contract, the Owner shall pay the cost of reexamination and replace-
If such work be found not in accordance with the contract, through the
of the Contractor, the Contractor shall pay such cost, unless he shall show
the defect in the work was caused by another contractor, and in that
the Owner shall pay such cost.

t. 14. **Correction of Work Before Final Payment.** The Contractor
promptly remove from the premises all materials condemned by the
tect as failing to conform to the Contract, whether incorporated in the
or not, and the Contractor shall promptly replace and re-execute his own
in accordance with the Contract and without expense to the Owner and
bear the expense of making good all work of other contractors destroyed
maged by such removal or replacement. If the Contractor does not
re such condemned work and materials within a reasonable time, fixed by
en notice, the Owner may remove them and may store the material at
xpense of the Contractor. If the Contractor does not pay the expense

of such removal within five days thereafter, the Owner may, upon ten written notice, sell such materials at auction or at private sale and account for the net proceeds thereof, after deducting all the cost and exp that should have been borne by the Contractor.

Art. 15. Deductions for Uncorrected Work. If the Architect Owner deem it inexpedient to correct work injured or not done in accord with the Contract, the difference in value together with a fair allowance damage shall be deducted.

Art. 16. Correction of Work After Final Payment. Neither the final tificate nor payment nor any provision in the Contract Documents shall the Contractor of responsibility for negligence or faulty materials or work ship and he shall remedy any defects due thereto and pay for any damag other work resulting therefrom, which shall appear within a period of two from the time of installation. The Owner shall give notice of observed with reasonable promptness. All questions arising under this Article be decided under Articles 10 and 45.

Art. 17. Protection of Work and Property. The Contractor shall tinuously maintain adequate protection of all his work from damage and protect the Owner's property from injury arising in connection with this tract. He shall make good any such damage or injury, except such as directly due to errors in the Contract Documents. He shall adequately p adjacent property as provided by law and the Contract Documents.

Art. 18. Emergencies. In an emergency affecting the safety of life or structure or of adjoining property, not considered by the Contractor as the provisions of Article 17, then the Contractor, without special instructio authorization from the Architect or Owner, is hereby permitted to act, at discretion, to prevent such threatened loss or injury and he shall so act, wi appeal, if so instructed or authorized. Any compensation claimed to be d him therefor shall be determined under Articles 10 and 45 regardless of limitations in Article 25 and in the second paragraph of Article 24.

Art. 19. Contractor's Liability Insurance. The Contractor shall tain such insurance as will protect him from claims under workmen's comp tion acts and from any other claims for damages for personal injury, inc death, which may arise from operations under this contract, whether operations be by himself or by any subcontractor or anyone directly or ind employed by either of them. Certificates of such insurance shall be filed the Owner, if he so require, and shall be subject to his approval for ade of protection.

Art. 20. Owner's Liability Insurance. The Owner shall maintain insurance as will protect him from his contingent liability for damag personal injury, including death, which may arise from operations under Contract.

Art. 21. Fire Insurance. The Owner shall effect and maintain fire ance upon the entire structure on which the work of this contract is to be and upon all materials, in or adjacent thereto and intended for use the to at least eighty per cent of the insurable value thereof. The loss, if is to be made adjustable with and payable to the Owner as Trustee for it may concern. All policies shall be open to inspection by the Contr If the Owner fails to show them on request or if he fails to effect or mai insurance as above, the Contractor may insure his own interest and c the cost thereof to the Owner. If the Contractor is damaged by failure

ner to maintain such insurance, he may recover under Art. 39. If required writing by any party in interest, the Owner as Trustee shall, upon the urrence of loss, give bond for the proper performance of his duties. He shall osit any money received from insurance in an account separate from all his er funds and he shall distribute it in accordance with such agreement as the ties in interest may reach, or under an award of arbitrators appointed, one by Owner, another by joint action of the other parties in interest, all other cedure being in accordance with Art. 45. If after loss no special agreement is de, replacement of injured work shall be ordered under Art. 24. The Trustee ll have power to adjust and settle any loss with the insurers unless one the contractors interested shall object in writing within three working days the occurrence of loss and thereupon arbitrators shall be chosen as above. Trustee shall in that case make settlement with the insurers in accordance h the directions of such arbitrators, who shall also, if distribution by arbitra- is required, direct such distribution.

rt. 22. **Guaranty Bonds.** The Owner shall have the right to require Contractor to give bond covering the faithful performance of the contract the payment of all obligations arising thereunder, in such form as the Owner prescribe and with such sureties as he may approve. If such bond is ired by instructions given previous to the receipt of bids, the premium l be paid by the Contractor; if subsequent thereto, it shall be paid by the ner.

rt. 23. **Cash Allowances.** The Contractor shall include in the contract all allowances named in the Contract Documents and shall cause the work overed to be done by such contractors and for such sums as the Architect direct, the contract sum being adjusted in conformity therewith. The tractor declares that the contract sum includes such sums for expenses and it on account of cash allowances, as he deems proper. No demand for enses or profit other than those included in the contract sum shall be allowed. Contractor shall not be required to employ for any such work persons nst whom he has a reasonable objection.

rt. 24. **Changes in the Work.** The Owner, without invalidating the ract, may make changes by altering, adding to or deducting from the work, contract sum being adjusted accordingly. All such work shall be executed r the conditions of the original contract except that any claim for extension me caused thereby shall be adjusted at the time of ordering such change. xcept as provided in Articles 3, 9 and 18, no change shall be made unless in uance of a written order from the Owner signed or countersigned by the itect, or a written order from the Architect stating that the Owner has orized the change, and no claim for an addition to the contract sum shall alid unless so ordered.

he value of any such change shall be determined in one or more of the wing ways:

) By estimate and acceptance in a lump sum.
) By unit prices named in the contract or subsequently agreed upon.
) By cost and percentage or by cost and a fixed fee.
) If none of the above methods is agreed upon, the Contractor, provided eceive an order as above, shall proceed with the work, no appeal to arbitra- being allowed from such order to proceed.

cases (c) and (d), the Contractor shall keep and present in such form as Architect may direct, a correct account of the net cost of labor and mate- , together with vouchers. In any case, the Architect shall certify to the

amount, including a reasonable profit, due to the Contractor. Pending determination of value, payments on account of changes shall be made on Architect's certificate.

Art. 25. Claims for Extras. If the Contractor claims that any ins- tions, by drawings or otherwise, involve extra cost under this contract, he give the Architect written notice thereof before proceeding to execute the and, in any event, within two weeks of receiving such instructions, and procedure shall then be as provided in Art. 24. No such claim shall be unless so made.

Art. 26. Applications for Payments. The Contractor shall submit to Architect an application for each payment and, if required, receipts or vouchers showing his payments for materials and labor as required by Article If payments are made on valuation of work done, such application shall submitted at least ten days before each payment falls due, and, if requi the Contractor shall before the first application, submit to the Architect schedule of values of the various parts of the work, including quantities, ag gating the total sum of the contract, divided so as to facilitate payments subcontractors in accordance with Article 44 (e), made out in such form, if required, supported by evidence as to its correctness, as the Architect direct. This schedule when approved by the Architect, shall be used basis for certificates of payment, unless it be found to be in error. In appl for payments, the Contractor shall submit a statement based upon this sche and, if required, itemized in such form, and supported by such evidence, as Architect may direct, showing his right to the payment claimed.

Art. 27. Certificates and Payments. If the Contractor has made appli tion as above, the Architect shall, not later than the date when each paym falls due, issue to the Contractor a certificate for such amount as he dec to be properly due. No certificate issued nor payment made to the Contrac nor partial or entire use or occupancy of the work by the Owner shall be acceptance of any work or materials not in accordance with this contract. making and acceptance of the final payment shall constitute a waiver of claims by the Owner, otherwise than under Articles 16 and 29 of these ditions or under requirement of the specifications, and of all claims by Contractor, except those previously made and still unsettled. Should Owner fail to pay the sum named in any certificate of the Architect or in award by arbitration, upon demand when due, the Contractor shall receive addition to the sum named in the certificate, interest thereon at the legal in force at the place of building.

Art. 28. Payments Withheld. The Architect may withhold or, on acco of subsequently discovered evidence, nullify the whole or a part of any certif for payment to such extent as may be necessary to protect the Owner loss on account of:

(a) Defective work not remedied.

(b) Claims filed or reasonable evidence indicating probable filing of clai

(c) Failure of the Contractor to make payments properly to subcontra or for material or labor.

(d) A reasonable doubt that the contract can be completed for the bal then unpaid.

(e) Damage to another contractor under Article 40.

When all the above grounds are removed certificates shall at once be iss for amounts withheld because of them.

Art. 29. Liens. Neither the final payment nor any part of the reta

entage shall become due until the Contractor, if required, shall deliver to Owner a complete release of all liens arising out of this contract, or receipts ill in lieu thereof and, if required in either case, an affidavit that so far has knowledge or information the releases and receipts include all the r and material for which a lien could be filed; but the Contractor may, y subcontractor refuses to furnish a release or receipt in full, furnish a l satisfactory to the Owner, to indemnify him against any claim by lien or rwise. If any lien or claim remain unsatisfied after all payments are e, the Contractor shall refund to the Owner all moneys that the latter be compelled to pay in discharging such lien or claim, including all costs a reasonable attorney's fee.

t. 30. **Permits and Regulations.** The Contractor shall obtain and pay ll permits and licenses, but not permanent easements, and shall give all es, pay all fees, and comply with all laws, ordinances, rules and regulations ng on the work, as drawn and specified. If the Contractor observes that ings and specifications are at variance therewith, he shall promptly notify rchitect in writing, and any necessary changes shall be adjusted under 24. If the contractor performs any work knowing it to be con- to such laws, ordinances, rules and regulations, and without such notice to rchitect, he shall bear all costs arising thereform.

t. 31. **Royalties and Patents.** The Contractor shall pay all royalties license fees. He shall defend all suits or claims for infringement ny patent rights and shall save the Owner harmless from loss on nt thereof, except that the Owner shall be responsible for all such loss the product of a particular manufacturer or manufacturers is specified; f the Contractor has information that the article specified is an infringe- of a patent he shall be responsible for such loss unless he promptly gives information to the Architect or Owner.

t. 32. **Use of Premises.** The Contractor shall confine his apparatus, torage of materials and the operations of his workmen to limits indicated w, ordinances, permits, or directions of the Architect and shall not unreason- encumber the premises with his materials. The Contractor shall not load rmit any part of the structure to be loaded with a weight that will endanger fety. The Contractor shall enforce the Architect's instructions regarding advertisements, fires and smoking.

t. 33. **Cleaning Up.** The Contractor shall at all times keep the premises rom accumulations of waste material or rubbish caused by his employees rk and at the completion of the work he shall remove all his rubbish from bout the building and all his tools, scaffolding and surplus materials, and leave his work "broom clean" or its equivalent, unless more exactly ied. In case of dispute the Owner may remove the rubbish and charge st to the several contractors as the Architect shall determine to be just.

t. 34. **Cutting, Patching and Digging.** The Contractor shall do all g, fitting, or patching of his work that may be required to make its several come together properly and fit it to receive or be received by work of other ctors shown upon, or reasonably implied by, the Drawings and Specifica- for the completed structure, and he shall make good after them, as the tect may direct. Any cost caused by defective or ill-timed work shall be by the party responsible therefor. The Contractor shall not endanger ork by cutting, digging, or otherwise and shall not cut or alter the work other contractor, save with the consent of the Architect

. 35. **Delays.** If the Contractor is delayed in the completion of the work

by any act or neglect of the Owner or the Architect, or of any employee of
or by any other contractor employed by the Owner, or by changes ordered in
work, or by strikes, lockouts, fire, unusual delay by common carriers, una
able casualties, or any causes beyond the Contractor's control, or by d
authorized by the Architect pending arbitration, or by any cause which
Architect shall decide to justify the delay, then the time of completion
be extended for such reasonable time as the Architect may decide. No
extension shall be made for delay occurring more than seven days before
therefor is made in writing to the Architect. In the case of a continuing
of delay, only one claim is necessary. If no schedule is made under Ar
no claim for delay shall be allowed on account of failure to furnish dra
until two weeks after demand for such drawings and not then unless
claim be reasonable. This article does not exclude the recovery of dam
for delay by either party under Article 39 or other provisions in the Co
Documents.

Art. 36. Owner's Right to Do Work. If the Contractor should ne
to prosecute the work properly or fail to perform any provision of this cont
the Owner, after three-days' written notice to the Contractor, may, with
prejudice to any other remedy he may have, make good such deficiencies
may deduct the cost thereof from the payment then or thereafter due
Contractor; provided, however, that the Architect shall approve both s
action and the amount charged to the Contractor.

Art. 37. Owner's Right to Terminate Contract. If the Contractor sh
be adjudged a bankrupt, or if he should make a general assignment for the be
of his creditors, or if a receiver should be appointed on account of his insolve
or if he should, except in cases recited in Article 35, persistently or repeat
refuse or fail to supply enough properly skilled workmen or proper material
if he should fail to make prompt payment to subcontractors or for materi
labor, or persistently disregard laws, ordinances or the instructions of the Ar
tect, or otherwise be guilty of a substantial violation of any provision of the
tract, then the Owner, upon the certificate of the Architect that sufficient c
exists to justify such action, may, without prejudice to any other right or re
and after giving the Contractor seven-days' written notice, terminate
employment of the Contractor and take possession of the premises and
materials, tools and appliances thereon and finish the work by whatever me
he may deem expedient. In such case the Contractor shall not be entitl
receive any further payment until the work is finished. If the unpaid bal
of the contract price shall exceed the expense of finishing the work, incl
compensation to the Architect for his additional services, such excess sh
paid to the Contractor. If such expense shall exceed such unpaid balance,
Contractor shall pay the difference to the Owner. The expense incurred
the Owner as herein provided, and the damage incurred through the C
tractor's default, shall be certified by the Architect.

Art. 38. Contractor's Right to Stop Work or Terminate Contract.
the work should be stopped under an order of any court, or other p
authority, for a period of three months, through no act or fault of the C
tractor or of any one employed by him, or if the Owner should fail to p
the Contractor, within seven days of its maturity and presentation, any
certified by the Architect or awarded by arbitrators, then the Contractor
upon three-days' written notice to the Owner and the Architect, stop wo
terminate this contract and recover from the Owner payment for all work
cuted and any loss sustained upon any plant or material and reasonable p
and damages.

t. 39. **Damages.** If either party to this contract should suffer damage in ıanner because of any wrongful act or neglect of the other party or y one employed by him, then he shall be reimbursed by the other party ıch damage. Claims under this clause shall be made in writing to the liable within a reasonable time of the first observance of such damage ıot later than the time of final payment, except in case of claims under e 16, and shall be adjusted by agreement or arbitration.

. 40. **Mutual Responsibility of Contractors.** Should the Contractor damage to any other contractor on the work, the Contractor agrees, upon ıotice, to settle with such person by agreement or arbitration, if he o settle. If such other contractor sues the Owner on account of lamage alleged to have been so sustained, the Owner shall notify the actor, who shall defend such proceedings at the Owner's expense and, judgment against the Owner arise therefrom, the Contractor shall pay isfy it and pay all costs incurred by the Owner.

t. 41. **Separate Contracts.** The Owner reserves the right to let other ıcts in connection with this work. The Contractor shall afford other con- ırs reasonable opportunity for the introduction and storage of their mate- ınd the execution of their work and shall properly connect and coordinate ›rk with theirs. If any part of the Contractor's work depends for proper tion or results upon the work of any other contractor, the Contractor shall :t and promptly report to the Architect any defects in such work that r it unsuitable for such proper execution and results. His failure so to :t and report shall constitute an acceptance of the other contractor's work and proper for the reception of his work, except as to defects which may ›p in the other contractor's work after the execution of his work. To the proper execution of his subsequent work the Contractor shall measure already in place and shall at once report to the Architect any discrepancy en the executed work and the drawings.

. 42. **Assignment.** Neither party to the Contract shall assign the con- without the written consent of the other, nor shall the Contractor assign ıoneys due or to become due to him hereunder, without the previous n consent of the Owner.

. 43. **Subcontracts.** The Contractor shall, as soon as practicable after gning of the contract, notify the Architect in writing of the names of ntractors proposed for the principal parts of the work and for such others e Architect may direct and shall not employ any that the Architect may ı a reasonable time object to as incompetent or unfit. If the Contractor ıbmitted, before signing the contract, a list of subcontractors and the e of any name on such list is required or permitted after signature of nent, the contract price shall be increased or diminished by the difference en the two bids. The Architect shall, on request, furnish to any subcon- r, wherever practicable, evidence of the amounts certified to on his ıt. The Contractor agrees that he is as fully responsible to the Owner e acts or omissions of his subcontractors and of persons either directly or ctly employed by them, as he is for the acts and omissions of persons di- employed by him. Nothing contained in the Contract Documents shall any contractual relation between any subcontractor and the Owner.

. 44. **Relations of Contractor and Subcontractor.** The Contractor to bind every subcontractor and every subcontractor agrees to be bound, e terms of the General Conditions, Drawings and Specifications, as far as able to his work, including the following provisions of this Article, unless

specifically noted to the contrary in a subcontract approved in writ adequate by the Owner or Architect. This does not apply to minor contracts.

The Subcontractor agrees:

(a) To be bound to the Contractor by the terms of the General Cond Drawings and Specifications and to assume toward him all the obligation responsibilities that he, by those documents, assumes toward the Owner.

(b) To submit to the Contractor applications for payment in such reas time as to enable the Contractor to apply for payment under Article 26 of General Conditions.

(c) To make all claims for extras, for extensions of time and for damag delays or otherwise, to the Contractor in the manner provided in the Ge Conditions for like claims by the Contractor upon the Owner, except that time for making claims for extra cost as under Article 25 of the General Co tions is one week.

The Contractor agrees:

(d) To be bound to the Subcontractor by all the obligations that the Ow assumes to the Contractor under the General Conditions, Drawings and Spe cations and by all the provisions thereof affording remedies and redress to Contractor from the Owner.

(e) To pay the Subcontractor, upon the issuance of certificates, if issued u the schedule of values described in Article 26 of the General Conditions, amount allowed to the Contractor on account of the Subcontractor's wor the extent of the Subcontractor's interest therein.

(f) To pay the Subcontractor, upon the issuance of certificates, if issued ot wise than as in (e), so that at all times his total payments shall be as larg proportion to the value of the work done by him as the total amount certifie the Contractor is to the value of the work done by him.

(g) To pay the Subcontractor to such extent as may be provided by Contract Documents or the subcontract, if either of these provides for ea or larger payments than the above.

(h) To pay the Subcontractor on demand for his work or materials as fa executed and fixed in place, less the retained percentage, at the time the ce cate should issue, even though the Architect fails to issue it for any caus the fault of the Subcontractor.

(j) To pay the Subcontractor a just share of any fire-insurance money rec by him, the Contractor, under Article 21 of the General Conditions.

(k) To make no demand for liquidated damages or penalty for delay in sum in excess of such amount as may be specifically named in the subcont

(l) That no claim for services rendered or materials furnished by the C tractor to the Subcontractor shall be valid unless written notice thereof is g by the Contractor to the Subcontractor during the first ten days of the cale month following that in which the claim originated.

(m) To give the Subcontractor an opportunity to be present and to su evidence in any arbitration involving his rights.

(n) To name as arbitrator under Article 45 of the General Conditions person nominated by the Subcontractor, if the sole cause of dispute is the w materials, rights, or responsibilities of the Subcontractor; or, if of the S contractor and any other subcontractor jointly, to name as such arbitrator person upon whom they agree.

The Contractor and the Subcontractor agree that:

(o) In the matter of arbitration, their rights and obligations and all proce shall be analogous to those set forth in Article 45 of the General Conditio

Nothing in this Article shall create any obligation on the part of the Owner pay to or to see to the payment of any sums to any Subcontractor.

Art. 45. Arbitration. Subject to the provisions of Article 10, all questions dispute under this contract shall be submitted to arbitration at the choice either party to the dispute. The Contractor agrees to push the work vigor-sly during arbitration proceedings. The demand for arbitration shall be d in writing with the Architect, in the case of an appeal from his decision, hin ten days of its receipt and in any other case within a reasonable time er cause thereof and in no case later than the time of final payment, except to questions arising under Article 16. If the Architect fails to make a ision within a reasonable time, an appeal to arbitration may be taken as his decision had been rendered against the party appealing. No one shall nominated or act as an arbitrator who is any way financially interested this contract or in the business affairs of either the Owner, Contractor or chitect. The general procedure shall conform to the laws of the State in ich the work is to be erected. Unless otherwise provided by such laws, parties may agree upon one arbitrator; otherwise there shall be three, named, in writing, by each party to this contract, to the other party and the Architect, and the third chosen by these two arbitrators, or if they fail select a third within ten days, then he shall be chosen by the presiding officer the Bar Association nearest to the location of the work. Should the party nanding arbitration fail to name an arbitrator within ten days of his demand right to arbitration shall lapse. Should the other party fail to choose an itrator within said ten days, then such presiding officer shall appoint such itrator. Should either party refuse or neglect to supply the arbitrators with papers or information demanded in writing, the arbitrators are empowered both parties to proceed ex parte. The arbitrators shall act with promptness. here be one arbitrator his decision shall be binding; if three the decision any two shall be binding. Such decision shall be a condition precedent to right of legal action, and wherever permitted by law it may be filed in urt to carry it into effect. The arbitrators, if they deem that the case nands it, are authorized to award to the party whose contention is sustained h sums as they shall deem proper for the time, expense and trouble incident the appeal and, if the appeal was taken without reasonable cause, damages delay. The arbitrators shall fix their own compensation, unless otherwise vided by agreement, and shall assess the costs and charges of the arbitration n either or both parties. The award of the arbitrators must be in writing, , if in writing, it shall not be open to objection on account of the form of proceedings or the award, unless otherwise provided by the laws of the te in which the work is to be erected. In the event of such laws providing any matter covered by this article otherwise than as hereinbefore specified, method of procedure throughout and the legal effect of the award shall wholly in accordance with the said State laws, it being intended hereby to down a principle of action to be followed, leaving its local application to be pted to the legal requirements of the place in which the work is to be erected.

For the convenience of the members of the Institute, and the profe generally, who use in their practice, by reference or otherwise, the vari official documents of the American Institute of Architects, the above sche of Titles and Prices is issued. On single copies of pamphlet-documents post will be prepaid, otherwise not. The prices quoted in practically every c are to cover the actual cost of printing and handling. The Institute has desire to make a profit on documents issued primarily for the benefit of t profession. For distinctly educational work, and for Chapter-work, no cha will be made for small quantities of documents, except for postage. Reque of this kind should come through the Chapter-Secretary or a Commit Chairman. Communications and remittances should be sent to the Execu Secretary, The Octagon House, Washington, D. C. All orders are filled the day received.

REGULATION OF THE PRACTICE OF ARCHITEC TURE BY STATE LEGISLATION *

States Having Registration Laws (1923). Twenty-three have regist tion or license laws (1923) for the practice of architecture: California, Colora Florida, Georgia, Idaho, Illinois, Louisiana, Michigan, Minnesota, Montana, Ne Jersey, New York, North Carolina, North Dakota, Oregon, Pennsylvania, Sou Carolina, Tennessee, Utah, Virginia, Washington, West Virginia, and Wiscons

Laws are pending (1923) in Indiana, Iowa, Kansas, and other states.

Theory of Registration Laws. The reason for the REGULATION OF ARCI TECTURAL PRACTICE BY LAW is the fact that men improperly qualified practice can otherwise, at will, assume the title of ARCHITECT and impose u the public, thereby discrediting the profession. In some States and in Ca it seems evident that legislation was enacted for protection of local archit against encroachment on the part of non-resident architects. Such a mot is unworthy of the profession, whose efforts through legislation should be encourage design of higher artistic quality and to insure safe construct Some laws, like the first one formulated (Illinois 1897), are LICENSE LAWS in they tax every architect. Other laws, that in New York, for example, a REGISTRATION LAWS, undertake to issue certificates only to those qualified practice. Registration laws should not in a retroactive way attempt to depr those of their right who, by virtue of having been in bona-fide practice the law was enacted, have the legal right to continue in such practice, sub to the effect of public sentiment which may be created against non-regis architects, and subject also to responsibilities imposed by building ordina requiring safe construction. The THEORY OF THE REGISTRATION LAW is an architect should attain to a certain minimum general education, a cert minimum technical education, plus a certain minimum of practical experie before beginning practice on his own account. That theory is carried effect by requiring under penalty that no person may assume the title ARCH whether he is a new practitioner, or an experienced practitioner from wit the State, without first establishing his qualifications and receiving a certi authorizing him to use that title. The NEW YORK STATE LAW, printed

* This matter was prepared by D. Everett Waid, President (1922) of the New Y State Board of Examiners and Registration of Architects.

th, is typical of recent laws which attempt to embody this theory. References re are made to this law and the notation also that the American Institute Architects is prepared to cooperate with any persons interested who desire improve upon the laws already passed when trying to secure in other States ch legislation as will tend to raise the standard of qualifications of architects. ch legislation will certainly achieve its highest end if looked upon as educanal in purpose. Incidentally it may be remarked that the best interests of will be conserved if earnest efforts are made toward a COMMON STANDARD ich will encourage reciprocal relations among the States. An architect o has demonstrated his qualifications by passing a proper examination in e State should not be harassed by repetitions of the test in other States which he may choose to practice.

Standards of Education. The GENERAL EDUCATION required under the w York law is the completion of a high-school course, or equivalent thereof; o the satisfactory completion of such courses in mathematics, history, and e modern language, as are included in two years of an approved institution nting the degree of A.B. Five years' PRACTICAL EXPERIENCE in the office a reputable architect, beginning after the high-school course, is required ore a candidate can take the TECHNICAL EXAMINATION conducted by the ard of Examiners. This technical examination is not required of graduates recognized schools of architecture who shall have had, also, three years' pracıl experience.

dministration of Registration Laws. In New York State, architects admitted to practice by the Regents of the University of the State, who ninister the law through a BOARD OF EXAMINERS AND REGISTRATION OF CHITECTS. In other States, the Boards of Examiners are appointed by the vernors.

pplication for Certificates. Application-blanks and information regard- admittance to practice, dates of examinations, etc., can be obtained by ressing the Board of Examiners and Registration of Architects, Education lding, Albany, N. Y. In other States, such inquiries may be addressed he Secretary of State.

Iodel Registration Law. Those interested in STATE LEGISLATION REGU- ING THE PRACTICE OF ARCHITECTURE AND THE EDUCATION OF ARCHITECTS secure copies of a bill issued to serve as a BASIC MODEL which, with suitable lifications, may be enacted in any State. Address the Secretary, American itute of Architects, The Octagon House, Washington, D. C.

GISTRATION OF ARCHITECTS IN THE STATE OF NEW YORK *

law in relation to the practice of architecture and the rules of the State Board of Examiners and Registration of Architects approved by the Regents of The University of the State of New York

he Assistant Commissioner and Director of Professional Education is in ge of universities, colleges, professional and technical schools, the execution he laws concerning the professions, and the relations and chartering of tutions. REGISTERED ARCHITECTS

General business law (L. 1909, Ch. 25) Chapter 20 of the consolidated la became a law February 17, 1909

Article 7-A, Registered Architects

Became a law April 28, 1915 (Laws of 1915, Chapter 454). As amended by Laws of 19 Chapter 77.

Section 77. Registered Architects.
Section 78. Board of Examiners.
Section 79. Qualifications. Examinations. Fees.
Section 79a. Certificates.
Section 79b. Violation of Article.

77. **Registered Architects.** Any person residing in or having a place of business in the State, who, before this article takes effect, shall not have been engaged in the practice of architecture in New York State, under the title of architect, shall, before being styled or known as an architect, secure a certificate of his qualification to practice under the title of architect, as provided by this article. Any person who shall have been engaged in the practice of architecture under the title of architect, before this article takes effect, may secure such certificate, in the manner provided by this article. Any person having a certificate pursuant to this article may be styled or known as a registered architect. No other person shall assume such title or use the abbreviation R. A., or any other words, letters or figures to indicate that the person using the same is a registered architect; but this article shall not be construed to prevent persons other than architects from filing applications for building permits or obtaining such permits.

78. **Board of Examiners and Registration.** There shall be a State Board of Examiners and Registration of Architects, who, and their successors, shall be appointed by and hold during the pleasure of the Board of Regents of the University of the State, and who, subject to the approval and to the rules of the Regents, may make rules for the examination and registration of candidates for the certificates provided for by this article. Such board of examiners shall be composed of five architects, who have been in active practice in the State of New York for not less than ten years, previous to their appointment, selected by the Regents. Such examiners shall be entitled to such compensation for their services under this article as the Board of Regents shall determine, not exceeding in the aggregate the amount of fees collected from applicants for certificates.

79. **Qualification. Examination. Fees.** Any citizen of the United States, or any person who has duly declared his intention of becoming a citizen, being at least twenty-one years of age and of good moral character, may apply for examination or certificate of registration under this article, but before securing such certificate shall submit satisfactory evidence of having satisfactorily completed the course in high school approved by the Regents of the University or the equivalent thereof and subsequent thereto of having satisfactorily completed such courses in mathematics, history and one modern language, as are included in the first two years in an institution approved by the Regents, conferring the degree of bachelor of arts. Such candidate shall

dition submit satisfactory evidence of at least five years' practical experience *the* office or offices of a reputable architect or architects, commencing after completion of the high school course. The board of examiners may accept isfactory diplomas or certificates from approved institutions covering the irse required for examination. Upon complying with the above require-nts, the applicant shall satisfactorily pass an examination in such technical l professional courses as are established by the board of examiners. The rd of examiners in lieu of examinations may accept satisfactory evidence any one of the qualifications set forth under subdivisions 1 and 2 of this tion.

. A diploma of graduation or satisfactory certificate from an architectural ege or school approved by the Regents, together with at least three years' ctical experience in the office or offices of a reputable architect or architects; the three years' experience shall be counted only as beginning at the com-ion of the course leading to the diploma or certificate; the State Board of aminers and Registration of Architects may require applicants under this division to furnish satisfactory evidence of knowledge of professional prac-;

. Registration or certification as an architect in another state or country, ere the qualifications required for the same are equal to those required in State;

. The board of examiners in lieu of all examinations shall accept satisfactory lence as to the applicant's character, competency and qualifications, and he has been continuously engaged in the practice of architecture for more n two years next prior to the date when this article shall take effect, or that ias been actually engaged in the practice of architecture on his own account s a member of a reputable firm or association for more than one year prior he date when this article shall take effect; providing the application for certification shall be made on or before January 1, 1918. Any architect has lawfully practiced architecture for a period of more than ten years iout the State shall be required to take only a practical examination, which l be of the nature to be determined by the State Board of Examiners and istration of Architects. Every person applying for examination or certifi- of registration under this article shall pay a fee of twenty-five dollars to Board of Regents.

a. Certificates. 1. The result of every examination, or other evidence ualification, as provided by this article, shall be reported to the Board of ents by the board of examiners, and a record of the same shall be kept he Board of Regents, and such board shall, unless deemed otherwise advis-, issue a certificate of registration to every person certified by the board aminers as having passed such examination or as being otherwise qualified e entitled to receive the same.

Every person securing such certificates shall register in the office of the ity clerk of the county in which he maintains a place of business, in a book by the clerk for such purpose, his name, residence, place and date of birth post office address, source, number and date of his certificate of registration ractice architecture and the date of such registration, which registration iall be entitled to make only upon showing to the county clerk his certificate gistration and making an affidavit of the above facts, and that he is the tical person named in the certificate; that before receiving the same he plied with all of the preliminary requirements of this article and the rules e Regents and the board of examiners as to the terms and the amount udy and examination; that no money other than the fees prescribed by

this article and such rules was paid directly or indirectly for such registr
and that no fraud, misrepresentation or mistake in material regard was
ployed or occurred in order that such certificate should be made, which and
shall be preserved in a bound volume by the county clerk. The county
shall indorse or stamp on the back of the certificate the date and his
preceded by the words "registered as authority to practice as a regis
architect, in the clerk's office of......................county"; and
issue to each person duly registering and making such affidavit a certific
of registration in his county which shall include a transcript of the registra
Such transcript and the certificate of registration may be offered as pres
tive evidence in all courts of the facts stated therein. The county cl
fee for taking such registration and affidavit and issuing such certificate s
be one dollar. Any person who, having lawfully registered as aforesaid, sh
thereafter change his name in any lawful manner, shall register the new na
with a marginal note of the former name, and shall note upon the margin
the former registration the fact of such change and a cross-reference to the
registration. A county clerk who knowingly shall make or suffer to be m
upon the book of registry of architects kept in his office any other entry th
is provided for in this article shall be guilty of a misdemeanor.

3. An architect having duly registered to practice as a registered architect
one county and removing his practice or a part thereof to another county
regularly engaging in practice or opening an office in another county, shall
or send, by registered mail, to the clerk of such other county, his certific
of registration. If such certificate clearly shows that the original registra
was duly issued under seal by the Board of Regents, the clerk shall thereup
register the applicant in the latter county on receipt of a fee of 25 cents
shall stamp or indorse on such certificate the date and his name, preceded
the words "Registered also in......................county," and retu
the certificate to the applicant.

4. The Board of Regents may revoke any certificate, if such action be reco
mended by the board of examiners, after thirty days' written notice to
holder thereof and after a hearing before the board of examiners, upon p
that such certificate has been obtained by fraud or misrepresentation, or
proof that the holder of such certificate has been guilty of felony in connecti
with the practice of architecture.

79b. Violation of Article. Any violation of this article shall be a
demeanor, punishable for the first offense by a fine of not less than fifty
not more than one hundred dollars, and for a subsequent offense by a
of not less than two hundred nor more than five hundred dollars, or impri
ment for not more than one year, or both.

SYNOPSIS OF SUBJECTS ON WHICH EXAMINATIONS ARE BASE

The examinations of applicants for certificates shall be based on the
following subjects or groups:

a. History of Architecture. The candidate shall give evidence in
examination that he understands the essentials that give character to
various historic styles of architecture by clear descriptive analyses of
construction, general expression and ornament. Questions will be a
relating to:

(1) Architecture in various countries.

* Taken from the Rules of the New York State Board of Examiners and Regist
of Architects.

(2) Styles and orders. Sketches and names of examples.
(3) Sculpture and painting and color as applied to architecture.
(4) Furniture and decoration.

). **Architectural Composition.** The candidate shall give evidence that understands the broad principles underlying the subject of architectural nning by the application of the same to specific problems stated in the mination. The social, economic and physical requirements of several hitectural problems will be outlined and the candidate will be asked to te the principal considerations that would guide him in the choice of an angement of plan that would most adequately express and fulfill the con- ions suggested. Small sketches will be required to illustrate the application the principles involved. Questions will refer to:

1) Principles of Planning: Problems in planning individual buildings, ups and towns; illustrations may be asked to show how plans may be uenced by considerations, esthetic, structural, and as to kinds of materials, l modifications of plan due to considerations of occupancy and of fire pre- tion both for fireproof and non-fireproof buildings.

2) Esthetic Design: Original examples will be required illustrating prin- es involved in the solution of practical problems and the relation of plan elevation.

. **Architectural Engineering.** In this examination the candidate shall evidence that he has a thorough understanding of the appropriate use the various materials used in buildings. He will be required also to solve ain technical problems such as the calculation of the proper economic ensions of various structural members common to buildings, in the several erials noted. Candidates will not be required to make complicated calcu- ons, and the use of handbooks will be permitted. Questions will be asked o the knowledge of these subjects that an architect should possess in order perly to advise his clients and to design or to direct the designing of suitable hanical equipment for buildings of different classes. Questions will be asked ting to:

) Structural Design:
olumn, girder, joist and truss designs.
Vind bracing for buildings of different classes.
arious types of foundations and conditions under which their use is advisable.
arious kinds of bottom met with in ordinary practice and unit loads allowable er foundations in each case.
ifferent types of concrete floor slab construction in common use.
tructural design as affected by fire and resistive qualities of different build- materials.

) Use of Materials:
trength of materials, durability and considerations of wear and repair.
sthetic reasons for use of different materials.

) Heating and Ventilating:
arious systems and reasons for and against use under specific conditions.
nportant features of design that should be specified.

) Electric Equipment: General questions rather than technical.
arious kinds of current and considerations involved.
inds of wiring and insulation; methods and materials.
ight distribution.
ighting fixtures; esthetic and practical design; important mechanical ils.

Generators, motors, storage batteries, and advice to clients regarding the same.

Independent power plant considerations.

(5) Plumbing and Fire Protection Equipment:

Supply and waste systems.

Kinds of material for piping and reasons for use.

Kinds of materials for fixtures.

Sewage disposal plants and considerations involved.

Water supply, different systems and considerations of supply and filtratio

Sprinklers and other fire protection equipment.

(6) Elevators:

Types of elevators.

Arrangement and location of elevators.

d. Architectural Practice. In this examination the candidate shall gi evidence that he understands the moral and the legal responsibilities of th architect in the proper performance of his duties as such. He will be requi to outline or draft clauses of contracts between owner and architect and state specifically the content of the clauses included in the contract betw owner and contractor which are incorporated for the purpose of defining t architect's authority and responsibility to both parties of the contract. Ea candidate will be required to show that he understands the major provisi of state, county and municipal building laws and ordinances and how the s affect the different classes of buildings. He shall be able also to cite the co petent authority under whose jurisdiction permits for the erection and occupa of various types of buildings must be obtained. Questions will be asked rel ing to:

(1) Business and Professional Functions of Architects:

Professional relation of clients and contractors.

Essential provisions in contract between architect and his client.

When the architect is disinterested arbitrator, and when he properly may a as an agent.

Relation of architects to each other in ordinary practice, in association, a in consultation, and when one architect displaces another on a given piece work.

Sources and kinds of compensation for architect's services.

Responsibilities of architects and methods of conducting their business.

Scope of architect's work, esthetic and structural.

When expert's services should be advised.

Scope of architect's work, administrative business, and legal contra arbitrations, court evidence, contractors in default, when counsel of clie lawyer should be advised.

(2) Building Laws:

State, county and municipal laws, ordinances and regulations, and h they affect different classes of buildings.

Filing drawings and specifications and obtaining permits.

(3) Contracts:

Drawings, specifications and agreement as essential parts of the custo contract between owner and builder.

Variations in kinds and forms of agreements and contracts.

Definition of architect's authority.

Provisions as to bids, letting contracts, unit prices, requisitions, certif and payments.

Insurance: fire, liability, compensation.

Bonding contractors.

(4) Specifications:

General conditions, purposes and scope.

Scope and purposes and limitations of general clauses.

Principles which should be observed in writing specifications.

Right and wrong methods of specifying qualities of materials and workman-ip.

(5) Drawings:

Purposes, use and limitations of preliminary drawings.

Essentials which should be embodied in contract drawings.

Purposes and limitations of detail and other working drawings which are t contract drawings.

REGISTRATION OF SCHOOLS OF ARCHITECTURE *

A school of architecture may be registered as maintaining a satisfactory indard and may be legally incorporated. Incorporation by the Regents will made on formal application and inspection by the Department which show at the school possesses the minimum requirements.

Application. An educational institution desiring admission to or incor-ration or registration by the University must file a written application giving information requested in the form prescribed by the Commissioner of ucation. A form will be mailed on application to the Assistant Commissioner Higher Education. Such application must be on file in the Education partment at least 10 days before the meeting of the Regents at which action reon is to be taken.

Accrediting. Institutions unable to meet the standards required by the gents for registration in full shall be accredited by the Department for one nore years of professional training as they meet the requirements for admission l for professional training set by the Regents standards.

Recognition Accorded Accredited Professional Schools. Professional ools registered by the Regents shall give the work of accredited institutions higher recognition than that accorded such institutions in the Department's redited list, viz.: (1) The successful completion of a four-year course in a fessional school accredited by the Department for three years shall be orded three years' recognition only; (2) the successful completion of a ee-year course in a professional school accredited by the Department for years shall be accorded two years' recognition only; (3) the successful npletion of a two-year course in a professional school accredited by the partment for one year shall be accorded one year's recognition only. A istered school may refuse to accord an accredited institution the recognition en it by the Department but it may not give it any higher recognition.

Comity of Action in the Transfer of Students from One Professional ool to Another. The Department does not consider a course in a school rchitecture satisfactory if more than two conditions, one major of 100 hours one minor of 50 hours, are allowed students for promotion from one year's s to the next.

*Taken from the Rules of the New York State Board of Examiners and Registration Architects. As schools may be added to the accredited lists, these lists must be sed from time to time.

REGENTS' RULES

Schools of Architecture *

440. Definitions. SCHOOL OF ARCHITECTURE means any college or sch of architecture, or school, department or course of architecture in a col or university, whatever the corporate title.

441. Requirements. A SCHOOL OF ARCHITECTURE, legally incorpora may be registered as maintaining proper standards. It must afford sa factory instruction in such technical and professional courses as are establis by the board of examiners, for admission to the examinations in the hist of architecture, architectural composition, architectural engineering and arc tectural practice.

442. General Education. A. PRELIMINARY. For admission to a sch of architecture, evidence shall be required showing the satisfactory complet of a four-year course in a secondary school approved by the Board of Regent or the equivalent, 72 counts in the academic examinations. B. HIGH For admission to the examinations for the certificate of R. A. evidence sh be required of such courses in mathematics, history and modern languages are included in the first two years of the curriculum leading to the degree bachelor in arts, or the equivalent, graduation from a junior college appro by the Board of Regents.

SCHOOLS OF THE UNITED STATES AND CANADA REGISTERED OR ACCREDITED.† JUNE, (1918)

Alphabetically Arranged by States

United States

California. REGISTERED: School of Architecture, University of Califor Berkeley. (Graduate course, one or two years.)

District of Columbia. REGISTERED: Department of Architecture, Geo Washington University, Washington. (Course, four years.)

Georgia. REGISTERED: Department of Architecture, Georgia School Technology, Atlanta. (Course, four years.)

Illinois. REGISTERED: Chicago School of Architecture, Armour Institute Technology, Chicago. (Course, four years.)

Department of Architecture, University of Illionis, Urbana. (Course, fo years.)

Indiana. REGISTERED: College of Architecture, University of Notre Dam Notre Dame. (Course, four years.)

Department of Architectural Engineering, Rose Polytechnic Institute, Ter Haute. (Course, four years.)

Kansas. Department of Architecture, Kansas State Agricultural Colleg Manhattan. (Course, four years.)

Department of Architectural Engineering, University of Kansas, Lawren (Course, four years.)

* Taken from the Rules of the New York State Board of Examiners and Registratio of Architects. As schools may be added to the accredited lists, these lists must b revised from time to time.

† This is the list of Schools or Departments of Architecture in the United States an Canada, registered or accredited by the New York State Board of Examiners and Regi tration of Architects, and must be added to from time to time.

Louisiana. REGISTERED: School of Architecture and Architectural Engi-
ering, Tulane University, New Orleans. (Courses, four years.)

Massachusetts. REGISTERED: Departments of Architecture and Archi-
tural Engineering, Massachusetts Institute of Technology, Cambridge.
ourses, four years.)

School of Architecture, Harvard University, Cambridge. (Graduate Course,
ee years.)

Michigan. REGISTERED: College of Architecture, University of Michigan,
n Arbor. (Course, four years.)

Minnesota. REGISTERED: Department of Architecture, University of
nnesota, Minneapolis. (Course, four years.)

Missouri. REGISTERED: School of Architecture, Washington University,
Louis. (Course, four years.)

Nebraska. REGISTERED: Department of Architectural Engineering, Uni-
sity of Nebraska, Lincoln. (Course, four years.)

New York. REGISTERED: College of Architecture, Cornell University,
aca. (Course, four or five years.)

Department of Architecture, Syracuse University, Syracuse. (Course, four
rs.)

School of Architecture, Columbia University, New York. (Course, four
rs.)

Ohio. REGISTERED: Department of Architecture, Ohio State University,
umbus. (Course, four years.)

Oklahoma. REGISTERED: Department of Architecture, Oklahoma Agri-
tural and Mechanical College, Stillwater. (Courses, four years.)

Pennsylvania. REGISTERED: Department of Architectural Engineering,
nsylvania State College, State College. (Course, four years.)

Department of Architecture, University of Pennsylvania, Philadelphia
ourses, four years.)

Department of Architecture, Carnegie Institute of Technology, Pittsburgh
ourse, four years.)

Texas. REGISTERED: Departments of Architecture and Architectural
gineering, Agricultural and Mechanical College of Texas, College Station.
ourses, four years.)

School of Architecture, University of Texas, Austin. (Course, four years.)

Canada

Ontario. REGISTERED: Department of Architecture, University of Toronto,
ronto. (Course, four years.)

Quebec. Department of Architecture, McGill University, Montreal.
ourse, five years.)

SYNOPSIS OF REGISTRATION LAWS *

This study † is made for those who would see at a glance the statutory
uirements for the practice of architecture throughout the United States.

* As States are added to the list of those which have laws for the Registration of
hitects, these lists must be revised from time to time. Georgia, Michigan, Penn-
rania, Virginia, and Washington have been added to the list, up to January, 1921.

† Taken from Handbook No. 35, published annually by The University of the State
New York, and containing information relating to the Registration of Architects.

There are four distinct lines of statutory requirements: (1) Preliminary e tion; (2) professional training; (3) licensing test; (4) registry. The items with (5) the title of the executive officer and the administrative are given uniformly in this synopsis.* If there are no statutory requirem the word "none" covers the item.

California. (1) None; (2) none; (3) examination; (4) with the recor of the county of residence annually; (5) secretary, State Board Architect San Francisco.

Colorado. (1) None; (2) none; (3) examination or certificate from similarly constituted board of another state; (4) with the secretary of state annually with the board; (5) Secretary, State Board of Examiners of Archi tects, Denver.

Idaho. (1) Approved high school course or its equivalent and in addition two-year course in English and mathematics such as is required in an approv B. A. course; (2) three years' practical experience in the office of a reputab architect; (3) examination or in lieu of all examinations, graduation from approved architectural school or registartion as an architect in another sta whose standard equals that of this board; (4) with the secretary of state; (Secretary, State Board of Examiners of Architects.

Illinois. (1) None; (2) none; (3) examination; (4) with the clerk of t county of practice, annually; (5) Secretary, Department of Registration a Examination, Springfield.

Louisiana. (1) Good primary education; (2) none; (3) examination diploma from an approved school of architecture; (4) with the district co clerk of the parish of residence and annually with the board; (5) Secreta Board of Architectural Examiners, New Orleans.

Montana. (1) None; (2) none; (3) examination or a license from anoth state board; (4) with the clerk and recorder of the county of residence a annually with the state treasurer; (5) Secretary, Board of Architectural Exam ners.

New Jersey. (1) None; (2) none; (3) examination or a license from similarly constituted board of another state or membership in the Americ Institute of Architects; (4) with the board, annually and with the secreta of state; (5) Secretary, State Board of Architects, Trenton.

New York. (1) Approved high school course or the equivalent and i addition such course in mathematics, history and one modern language as a included in an approved two-year B. A. course; (2) at least five years' practic experience in the office of a reputable architect; (3) examination or graduati from an approved architectural school with three years' experience or regi tration in another state or country having standards equal to that of this boar (4) with the Board of Regents; (5) Secretary, State Board of Examiners a Registration of Architects, New York.

North Carolina. (1) Prescribed by the board; (2) prescribed by t board; (3) examination or a certificate from a similarly constituted board i another state or membership in the American Institute of Architects; (with the clerk of the superior court of the county of residence; (5) Secretary the Board of Architectural Examination and Registration.

North Dakota. (1) Approved high school course or its equivalent; (three years' practical experience in the office of a reputable architect; (

* The names of the executive officers, Secretaries of the Boards, etc., are omitt here, as the personnel is constantly changing.

amination or a license from another state board whose standard equals that this board or membership in the American Institute of Architects; (4) with e secretary of state and annually with the board; Secretary, State Board of rchitecture, Bismarck.

South Carolina. (1) None; (2) at least two years' experience in archictural work; (3) examination or graduation from an approved school of chitecture; (4) with the board, annually; (5) Secretary, State Board of rchitectural Examiners, Columbia.

Utah. (1) None; (2) none; (3) examination; (4) with the board, annually;) Secretary, State Board of Architecture.

Wisconsin. (1) None; (2) at least five years' practical experience in the fice of a reputable architect; (3) examination or a satisfactory certificate om a recognized architectural school with three years' experience or registraon with the board of another state or country whose standards are not lowe an those of this board; (4) with the Industrial Commission; (5) Secretary the Board of Examiners of Architects, Madison.

DUCATIONAL INSTITUTIONS IN THE UNITED STATES AND CANADA OFFERING COURSES IN ARCHITECTURE. TRAVELLING FELLOWSHIPS AND SCHOLARSHIPS

1. Association of Collegiate Schools of Architecture

Association of Collegiate Schools of Architecture. Organized in 1912 advance the standards of architectural education in the United States. lembership (1921) represents fifteen architectural schools in Columbia, ornell, Harvard, Syracuse, Yale, and Washington Universities; the Universities f California, Illinois, Kansas, Michigan, Minnesota, Oregon and Pennsylvania, nd the Carnegie and Massachusetts Institutes of Technology. (Officers 1921: resident Emil Lorch; Vice-President, William Emerson; Secretary-Treasurer, larence A. Martin, Cornell University, Ithaca, N. Y. The Association equires for the admission of an institution to membership the attainment of ertain MINIMUM CONDITIONS in its course in architecture, a detailed list of which will be furnished upon application to the secretary. They are here roadly summarized as follows: (1) Collegiate rating under the Carnegie oundation; (2) A course of at least 120 CREDIT-HOURS of both general and rofessional studies of certain minimum range and approved method of presenation, leading to a degree not less than BACCALAUREATE; (3) Such character f staff and administration, standing of course and adequacy of equipment s will reasonably assure quality of performance; (4) A demonstration of sucess in operation through a period of at least four years. The Association olds an annual conference on architectural education to which representatives f all American schools are welcomed.

2. Educational Institutions, Fellowships, and Scholarships

Academy of Architecture and Industrial Science, St. Louis, Mo. This s a private school founded by Mr. Maack in 1885, and designed more paricularly to meet the wants of building tradesmen, offering them such instruction s is necessary to attain the highest proficiency in their trade and a thorough

understanding of the plans and details of complicated buildings. The also a special course for those desiring to fit themselves for positions as draug men in architects' offices. Tuition for the regular course is $50 for a th months' term, or $300 for the full course of eight terms, or $100 for the y Several special courses with varying tuition.

Alabama Polytechnic Institute, Auburn, Ala. DEPARTMENT ARCHITECTURE. (1) Full four-year course leading to the degree of Bach of Science in Architecture. (2) Full four-year course leading to the deg of Bachelor of Science in Architectural Engineering. (3) Two-year speci course for draftsmen and college graduates. Tuition free to residents Alabama; $20 per year for others. About two dozen LOAN-SCHOLARSHIPS $100 or more per annum. Limited number of FELLOWSHIPS of $250 for p graduates. Illustrated Announcement giving details, sent on request.

American Academy in Rome, Fellowship in Architecture. RO PRIZE. The fellowship is awarded annually and is of the value of $1 000 a y for three years. The award is made on competitions which are open only unmarried male citizens of the United States, who comply with the regulati of the Academy. Candidates are required to be (1) graduates of one of t architectural schools included in the accepted list of the Academy; or (2) gr uates of a college or university of high standing who hold certificates of at le two years' study in one of such architectural schools; or (3) Americans w are pupils of the first class of the School of Fine Arts at Paris, and who ha obtained at least three values in that class. There is no age-limit. Informati as to the terms and conditions of the competitions may be obtained from t Secretary of the Academy, 101 Park Avenue, New York City.

American School of Correspondence, Chicago, Ill. Correspondenc courses in Architecture, Architectural Engineering, Contracting and Building Reinforced Concrete, Architectural Design, and Structural Draughting. Bul tin sent on application.

Armour Institute of Technology, Chicago, Ill. Full four-year cou leading to the degree of Bachelor of Science in Architecture. Applicants f admission must have completed the regular four-year high-school cours A HOME TRAVELING-SCHOLARSHIP, four prizes, and a medal are awarded ann ally. Tuition, $180 per year.

Beaux Arts Institute of Design, 126 East 75th Street, New York, N.Y. DEPARTMENT OF ARCHITECTURE. (Address all communications to this depart ment.) The course, established in 1893, consists (1920) of a series of thirty-fi competitions, issued annually, for the study of architectural design and the sty of architecture, open to the draughtsmen and students in architectural schoo in the United States and Canada, and modeled on the system of instructi adopted by the École des Beaux Arts in Paris. The course is free, except fo the annual fee of $2 for registration of each student. There are no restrictio as to the age, nationality, or sex of the students. No preliminary examinatio are given, but new students are expected to have a knowledge of the five orde of architecture. BRONZE AND SILVER MEDALS are awarded for excellence i design and money-prizes are offered in special prizes for decoration, grou planning of buildings, etc. CERTIFICATES are presented to all students o Class A completing the course as defined in the circular of information, which is furnished on request. During the season 1917–1918 the work was carri on by one hundred and eleven correspondents of the Institute in eighty-eigh different cities, with a total of seven hundred and seventy-four students.

DEPARTMENT OF INTERIOR DECORATION (Address all communications to thi

partment): The course consists of programmes for competitions issued ery six weeks to those who apply for them. These may be executed by idents situated in any locality and sent in to the Institute where they will criticized and judged on fixed dates by a jury of experts. BRONZE AND VER MEDALS are awarded for excellence. An atelier for male students under instruction of several decorators exists in the building of the Institute. ere are no fees of any kind. No formalities or examinations are necessary admission to the atelier. A circular is furnished on request.

DEPARTMENT OF SCULPTURE. (Address all communications to this depart-nt.) Ateliers for male students for each one of the three courses (Archi-tural Ornament, Life Drawing, and Modeling and Composition) exist in building of the Institute. No examinations, formalities, or fees of any id. Open all day all the year round. Instructors visit their classes twice veek. Judgments by expert juries every four weeks on work of preceding nth. BRONZE AND SILVER MEDALS awarded. Circular furnished.

DEPARTMENT OF MURAL PAINTING. (Address all communications to this partment.) The course consists of problems, programmes of which are ied every month to those who apply for them. Judgments by a jury of ists every month on the designs handed in. BRONZE AND SILVER MEDALS arded. No examinations, formalities, or fees of any kind. No atelier this department at the Institute. Students work up their problems under ir own instructors wherever they may be situated. Circular furnished.

BEAUX ARTS ARCHITECTS, SOCIETY OF. 126 EAST 75TH STREET, NEW RK, N. Y. The course in Architectural Design established in 1893 and merly conducted by the Committee on Education of this Society, is now ried on by the Beaux Arts Institute of Design. (See Beaux Arts Institute Design.)

PARIS PRIZE. THIS SCHOLARSHIP-PRIZE is usually conducted annually by Society of Beaux Arts Architects. Under its conditions the winner re-ves $1 200, per annum for two years and a half, to study architecture in ris at the Ecole des Beaux Arts, into the upper class of which he is received thout further examinations. The competition beginning January 10th, 20, for this scholarship consisted of two preliminaries and one final com-tition and was open to all male citizens of the United States under thirty-two ars of age on July 1st, 1920. A circular is furnished on request.

Carnegie Institute of Technology, Pittsburgh, Pa. DIVISION OF THE TS; SCHOOL OF ARCHITECTURE. (1) A complete course in architecture for day-idents for which the degree of Bachelor of Architecture in Design is awarded those specializing in design and allied subjects (Option 1), and the degree of chelor of Architecture in Construction to those in construction and allied bjects (Option 2). From four to five years are required for the completion of escribed work. (2) For graduate day-students a course of advanced studies design and allied subjects, scheduled to cover one year, and leading to the gree of Master of Arts. (3) A partial day-course, scheduled to cover two ars, for experienced draughtsmen and designers, for which a certificate of oficiency is awarded. (4) A course for night-students for which a Certificate Proficiency is awarded. This course includes the same work as is required day-students in design, freehand drawing and modeling. Tuition: For day-hool, $75; for night-school, $20 per year.

Catholic University of America, Washington, D. C.

Clemson Agricultural College of South Carolina, Clemson College, S. C.

Columbia University, New York, N. Y. SCHOOL OF ARCHITECTURE.) Full four-year course leading to the degree of Bachelor of Architecture.

Receives only students with at least two years of college training. In connection with Columbia College, there is a six-year course giving the d of A.B., at the end of four years and B.Arch. at the end of six years. Advanced courses leading to the degree of Master of Science in Architec Tuition $6 per "tuition-point," totaling about $250 per year. There are th TRAVELING-FELLOWSHIPS, awarded as follows: One is available each y with a stipend of about $1 500; the McKIM FELLOWSHIP every third y beginning 1916–17; the SCHERMERHORN FELLOWSHIP, every third year, beg ning 1918–19; and the PERKINS FELLOWSHIP, every third year, begin 1920–21. Each of these requires the winner to devote one year to for travel and study.

EXTENSION-TEACHING, evening and afternoon courses. A course lead to a Certificate of Proficiency in Architecture is offered. This covers roug six years, depending on how much is taken each year. Equivalent of day-co in instruction. Tuition, $6 per "tuition-point," each course having a st point-value. Graduation accepted in lieu of examinations for state lice There are Special Students, also, under Extension-Teaching who select th own course of study in subjects for which they are qualified. All informati may be obtained from the Curator.

Cornell University, Ithaca, N. Y., COLLEGE OF ARCHITECTURE. (1) four-year general course in architecture, leading to the degree of Bach of Architecture, and a similar course with engineering electives, leading to th degree of Bachelor of Science in Architecture. (2) Five-year courses in arc tecture, the same as the above, but with additional work in the arts and scienc leading to the same degrees. (3) Six-year courses in arts and sciences an architecture, or in engineering and architecture, leading to the degrees of A and B.Arch., or C.E. and B.S.Arch. (4) A two-year special course in arc tecture, leading to a certificate. (5) Graduate courses in architecture, lead to the degree of Master of Architecture. Tuition, $200 a year.

George Washington University, Washington, D. C. DEPARTME OF ARTS AND SCIENCES. Course in Architecture. Four-year course in arc tecture, leading to the degree of Bachelor of Science in Architecture. Courses instruction open to qualified special students, without reference to any degr Full tuition $180; part-time students pay $6 for each semester-hour credit.

Georgia School of Technology, Atlanta, Ga. DEPARTMENT OF ARCH TECTURE. (1) Full four-year course leading to the degree of Bachelor Science in Architecture. (2) Two-year special course leading to a certificate proficiency. Tuition, $25 per year for residents of Georgia; $100 for no residents. The Georgia Chapter of the American Institute of Architects ha provided a loan-fund in this department for one or two students needi assistance.

Harvard University, Faculty of Architecture, Cambridge, Mas SCHOOL OF ARCHITECTURE. Professional training in architecture. (1) Ope to graduates of colleges, scientific schools and professional schools of good stan ing, leading to the degree of Master in Architecture, or Master in Architectu in Architectural Engineering. Length of period of study for men with professional preparation, commonly three years, depending on ability and pr vious training. (2) Open to competent special students, who must be ov twenty-one years of age, and must have had at least three years of offic experience; admitted to special course leading to certificate. Tuition $20 per year.

Howard University, Washington, D. C.

chool of Landscape-Architecture. (1) Professional training in landscape-hitecture, open to graduates of colleges and technical schools of good standing, ling to the degree of Master in Landscape-Architecture. (2) Special lents admitted to courses for which their training fits them. Tuition, $200. 'wo Traveling-Fellowships, the Julia Amory Appleton and the Robin-, are offered for competition in alternate years, each having an annual ıe of $1 100, tenable for two years, for travel and study in Europe under direction of the School of Architecture. The Charles Eliot Fellow-› in Landscape-Architecture (stipend $1 100) is offered for travel and ly in landscape-architecture, under the direction of the School of Landscape-hitecture. These fellowships are open for competition to graduates in ıitecture and in landscape-architecture, respectively.

esident Scholarships. Two Austin Scholarships in Architecture and in Landscape-Architecture, annual value, $350. The Cummings olarship in Landscape-Architecture, annual value, $350. One Eveleth olarship in Architecture, annual value, $250. Three Scholarships Special Students in Architecture, open to competition to properly lified draughtsmen, annual value, $200. Six University Scholarships open egular students in Architecture or Landscape-Architecture, annual value, o. Other scholarships available to candidates of special claims as to resi-ce, college, or descent.

nternational Correspondence Schools, Scranton, Pa. A corporation ıed to furnish instruction by correspondence and to hold examinations to blish proficiency. The architectural course is designed particularly to meet wants of those already engaged in the building trades or drafting-room. ıcludes sixty-one subjects covering the elements of building-construction, onry, carpentry, plumbing, etc., and the principles of design, drawing, ering, and specification-writing. The tuition includes text-books and uction, that is, criticisms on written lessons, sent to the schools, and also vers to questions on subjects connected with the course, that may be asked the students. Information regarding fees can be obtained on inquiry. ter courses are available for building-contractors, building-foremen, and special courses in structural engineering.

wa State College of Agriculture and Mechanic Arts, Ames, Iowa.

ansas State, Agricultural College of, Manhattan, Kan. Department rchitecture. Full four-year course in architecture, leading to a degree in elor of Science. Tuition free to residents of the state. Incidental fees unt to about $12 a semester.

lassachusetts Institute of Technology, Boston, Mass. Two four-year ses are offered in architecture, leading to the degree of Bachelor of Science: Course in general architecture; (2) Course in architectural engineering. ortunities are offered in each course for advanced professional work leading e degree in (1) of Master in Architecture and in (2) of Master of Science. ial students must be college-graduates, or twenty-one years of age, with not than two years of office-experience. In all cases they must demonstrate r fitness for the work of the department by personal conference with the l of the department, or his representative, and by the presentation of rs from former employers, together with drawings covering their experience ılly as possible. All special students must take in their first year of residence e Institute courses in descriptive geometry and mechanical drawing, unless e subjects have been passed at the September examinations for advanced ding, or excuse from one or both has been obtained on the basis of equivalent

work accomplished elsewhere. Tuition, $250 per year. An ANNUAL TRAVEL FELLOWSHIP amounting to $1 000 is given solely on the basis of disting merit, candidates being received from both regular and special students. prizes, varying from $10 to $200 each, are equally divided between the re and the special students. Certain funds are available for the assistance of qualified regular students for undergraduate and for post-graduate work.

McGill University, Montreal, Canada. DEPARTMENT OF ARCHITECTU (1) Full five-year course leading to the degree of Bachelor of Architec (2) Competent special students are admitted to take a partial course, but university certificate is granted for this work. Tuition, $150 per year.

North Dakota Agricultural College, Fargo, N. D. DEPARTMENT ENGINEERING. Draughtsmen's and builders' course of three years (six mo each). Full four-year course in architecture, leading to Bachelor of Scienc Architecture. Full four-year course in Architectural Engineering, lea to Bachelor of Science in Architectural Engineering. Tuition free. amounting to $35 per year.

Ohio Mechanics' Institute, Cincinnati, Ohio. DEPARTMENT OF ARC TECTURE. Technical high-school course preparatory to architecture, co ing four years. Two-year intensive course in architecture. Evening cl in architectural drawing and allied building-trade subjects. Graduates grammar-schools are trained in draughting and elementary architect subjects simultaneously with their high-school subjects. Graduates of hi schools are trained intensively in technical architectural work, including co giate mathematics and sciences, and receive a Certificate of Proficiency Architecture. Tuition, $75 per year.

Ohio State University, Columbus, Ohio. COURSE IN ARCHITECTU Two four-year courses, leading to the degrees of Bachelor of Architecture Bachelor of Architectural Engineering. Tuition free.

Oklahoma Agricultural and Mechanical College, Stillwater, Ok DEPARTMENTS OF ARCHITECTURE AND ARCHITECTURAL ENGINEERING. F year course in Architecture and Architectural Engineering, leading to a deg of Bachelor of Science. Two-year special course for draftsmen, leading to certificate of completion in this work. Tuition free. The registration-fee $2 a semester.

Pennsylvania State College, State College, Pa. Course in Archi tural Engineering. Full four-year course, leading to the degree of Bach of Science in Architectural Engineering. Tuition is free. Incidental amount to about $30 per semester, these fees including the college fees course in architectural design.

Pratt Institute, Brooklyn, N. Y. Course in Architecture. SCHOOL FINE AND APPLIED ARTS. (1) Two-year course in architectural design. Two-year course in architectural construction. (3) Full three-year course architectural design and architectural construction. The course in ar tectural design aims to give students a general training that will prepare th to pursue the profession of architecture as competent assistants in archite offices, and leads to positions of responsibility and independence. The co in architectural construction aims to fit the student for general draughting builders' offices, or for general detailing and construction-work in an archit office, and leads to the position of superintendent of construction-work. Tuiti $80 per year.

Princeton University, Princeton, N. J. SCHOOL OF ARCHITECTU

e courses in Architecture: (1) For students enrolled as candidates for egree of Bachelor of Arts on graduation and for the degree of Master of Arts in Architecture after two years of graduate work. (2) For students have not begun the study of architecture in the sophomore year, but wish to receive the degree of Bachelor of Arts on graduation and the degree aster of Fine Arts in Architecture after two years of graduate work. 'or students entering the School as candidates for the degree of Master ne Arts in Architecture without previous study in architecture. For the ge student, three years and a half are required for this course. Tuition, a year for students on full time, and $40 for those on part time. Annual $15. The GRADUATE FELLOWSHIP AND SCHOLARSHIPS of the University pen to members of the School. They are over fifty in number, and range pend from $150 to $1 000 per annum.

ce Institute, Houston, Tex. ARCHITECTURAL DEPARTMENT. Full year course leading to the degree of Bachelor of Science in Architecture. on free.

chester Athenaeum and Mechanics Institute, Rochester, N. Y. RTMENT OF APPLIED ARTS. Three-year courses in Architectural Drawing Design, and Architectural Construction, leading to Diplomas. There lso courses for properly prepared students who do not wish to take the ma-courses. Tuition for full courses, $90 per year; for part-time students, r term of twelve weeks for one session per week.

se Polytechnic Institute, Terre Haute, Ind. DEPARTMENT OF ARCHI-TRAL ENGINEERING. Full four-year course, designed to give a thorough ing in architectural engineering, together with systematic instruction in tectural design. Tuition and incidental fees, $110.

tch Traveling-Scholarship, Inc. (For particulars address the Secretary, eacon Street, Boston, Mass.) Candidates must be under thirty years of t the date of the beginning of the preliminary examinations. At that they must have been engaged in professional work during two years assachusetts in the employ of a practicing architect resident in Massa-tts, and will be required to pass preliminary examinations upon the follow-subjects: (1) History of architecture; (2) Freehand drawing from the (3) Construction, theory and practice; (4) An elementary knowledge e French language. Holders of a degree in Architecture from the Massa-tts Institute of Technology, Columbia University, University of Penn-nia, Cornell University, Harvard University, or University of Illinois be allowed to present such diploma which will be accepted in lieu of the inations in the preliminaries. Candidates who pass in these preliminary inations are admitted to a competition in design, the successful can-e in which is awarded the scholarship and receives annually, for two , $1 400, to be expended in foreign travel and study. The Boston Society chitects, through a committee, has complete charge of the examinations, supervises the work of the scholar. The Society of Architects awards um of $75 as a second prize.

racuse University, Syracause, N. Y., College of Fine Arts. DEPART-OF ARCHITECTURE. This school offers: Four-year courses in (1) Archi-re, (2) Architectural Design, (3) Architectural Engineering, all leading e degree of Bachelor of Architecture (B.Ar.); (4) Special two-year course rchitectural draughtsmen of two or more years' experience; (5) Graduate e in architecture; (6) Interior architectural design and decoration.

Tuition, $150 per year. Bulletins and full information available fr… Registrar.

University of Minnesota, Minneapolis, Minn. DEPARTMENT OF ARC… TECTURE. Full four-year course, leading to the degree of Bachelor of Sci… in Architecture. Fifth year, leading to the degree of Master of Scienc… Architecture. Special students of maturity and practical experience… admitted. Instruction is provided in Architectural Engineering. Tuition f… Incidental fee, $60 per year.

University of Nebraska, Lincoln, Neb. COLLEGE OF ENGINEER…

four-year course in architectural engineering, leading to Bachelor of Science rchitectural Engineering. Tuition free. Total fees for four years, $110.

niversity of Notre Dame, Notre Dame, Ind. DEPARTMENT OF ARCHI-URE. (1) Full four-year course in design leading to the degree of Bachelor cience in Architecture. (2) Full four-year course in architectural enging leading to the degree of Bachelor of Science in Architectural Engineering. Two-year special course leading to a Certificate of Proficiency. Tuition, per year; room $60 and upwards; board, $180 and upwards.

niversity of Oregon, Eugene, Ore. SCHOOL OF ARCHITECTURE AND ED ARTS. Two architectural options in design and structural work. Four-year course leading to the degree of Bachelor in Architecture. Five-year course leading to the degree of Master in Architecture. (3) Exon-courses in Portland, Ore., in design, etc. (4) Special courses for exnced draughtsmen. Tuition free for university-courses; $5 a term for nsion-courses.

niversity of Pennsylvania, Philadelphia, Pa. SCHOOL OF FINE ARTS, ARTMENT OF ARCHITECTURE. (1) Four-year course leading to the degree achelor of Architecture. (2) Graduate course of one year, with choice een major subjects, leading to the degree of Master of Architecture. Two-year special course leading to a professional certificate. (4) Six-year ngement of courses in liberal arts and architecture leading to the degrees . B. and also B. Arch. (5) Option in Architectural Engineering leading to degree of Bachelor of Architecture. Summer school providing instruction any architectural subjects of the regular session. The degree and certificate accepted by the American Institute of Architects in satisfaction of its ational requirements for membership and are credited by State Boards for sing of architects. Tuition $300 per year. Circular, including information ll courses in the School of Fine Arts, on application to the Dean of the School ine Arts, University of Pennsylvania, Philadelphia, Pa.

HE WOODMAN SCHOLARSHIP IN ARCHITECTURE of the University of Pennania, for one year of foreign travel and study, is open to graduates of this ol, they being also eligible to the general competition for the FELLOWSHIP HE AMERICAN ACADEMY IN ROME. The PARIS PRIZE OF THE BEAUX-ARTS ITUTE OF DESIGN is open to seniors and graduates and the STEWARDSON VELING-SCHOLARSHIP is available to students who are residents of Pennania. The MEDALS OF THE AMERICAN INSTITUTE OF ARCHITECTS and the ÉTÉ DES ARCHITECTES DIPLÔMÉS are conferred in this school as well as ER MEDALS AND PRIZES open to its students alone.

niversity of Santa Clara, Santa Clara, Cal.

niversity of Southern California, Los Angeles, Cal. Four-year general se in architecture, leading to the degree of B.S. in Architecture.

niversity of Texas, Austin, Tex. SCHOOL OF ARCHITECTURE. (1) Four- and five-year courses leading, respectively, to the degrees of Bachelor cience in Architecture, and Master of Science in Architecture. (2) Four- course leading to the degree of Bachelor of Science in Architectural Enering. Tuition free.

niversity of Toronto, Toronto, Canada. DEPARTMENT OF ARCHI-TURE. Full four-year course leading to the degree of Bachelor of Applied nce (B.A.Sc.) with an option of architectural engineering, replacing archiural design in the fourth year. The fees are, first year, $100; second year, o; third and fourth years, $120. The university is supported by the vince of Ontario.

University of Virginia. McIntire School of Fine Arts. Fo[ur-year] course in architecture, leading to the degree of Bachelor of Science in [Archi]tecture. Annual average of tuition and laboratory fees: For non-Virg[inians,] $180; for Virginians, $75.

University of Washington, Seattle, Wash. Course in Archite[cture]. Four-year course, leading to the degree of Bachelor of Architecture. Th[ere is] a fourth-year option in architectural engineering. Tuition, $20 per [year]. Entrance fee, $10; graduation fee, $5.

Washington, The State College of, Pullman, Wash. Departmen[t of] Architecture. (1) Full four-year course leading to the degree of Bach[elor] of Science in Architecture. (2) Two-year special course leading to a Certi[ficate] of Proficiency. (3) Special students, adequately prepared, are admitted t[o] classes. Tuition free.

Washington University, St. Louis, Mo. School of Architec[ture]. (1) Four-year courses in architecture and in architectural engineering le[ading] to the degrees of Bachelor of Architecture, and Bachelor of Science in A[rchi]tectural Engineering, respectively. (2) One-year course leading to the de[gree] of Master of Architecture. (3) Special two-year course with Certific[ate]. Tuition, $150 per year.

Wentworth Institute, Boston, Mass. Courses in architectural c[on]struction, carpentry and building, and twelve other technical trades or in[dus]tries. (1) Two-year course in architectural construction trains for posit[ions] of foremen, superintendents, detail-designers, etc. Tuition, $54 per year a[nd] $15 laboratory fee. (2) One-year course in carpentry and building pla[nned] for those wishing to enter the wood-working-trades and industries as advan[ced] apprentices or high-grade artisans. Tultion $30 per year and $15 laboratory f[ee].

Yale University, New Haven, Conn. Department of Architectu[re]. Regular course covers four years. Special degree, Bachelor of Fine Arts, [may] be competed for at end of course. Portions of the first-year's work, incl[uding] lectures on history of chief styles of architecture and principles of composi[tion] and practice in elementary design, may be taken as electives by juniors a[nd] seniors in the academic course. Alice Kimball English Scholarship, [sup]ported from fund of $11 000, for a year's travel abroad. William Wirt W[in]chester Scholarship, supported from fund of $20 000, for a year's t[ravel] abroad. Tuition, $180 per year.

GLOSSARY *

Technical Terms, Ancient and Modern, Used by Architects, Buil and Draughtsmen

Aaron's-Rod. An ornamental figure representing a rod with a serpent twi about it. It is sometimes confounded with the caduceus of Mercury. T distinction between the caduceus and the Aaron's-rod is that the former has tw serpents twined in opposite directions, while the latter has but one.

Abacus. The upper member of the capital of a column. It is sometim square and sometimes curved, forming on the plan segments of a circle called the arch of the abacus, and is commonly decorated with a rose or other ornament in the center, having the angles, called horns of the abacus, cut off in the direction of the radius or curve. In the Tuscan or Doric, it is a square tablet; in the Ionic, the edges are molded; in the Corinthian, its sides are concave and frequently enriched with carving. In Gothic pillars it has a great variety of forms.

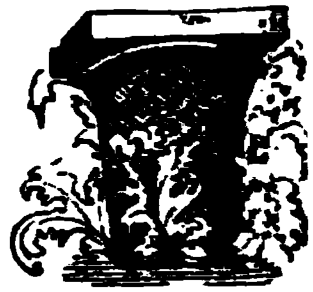
CORINTHIAN ABACUS

Abbey. A term for the church and other buildings used by conventual bodies presided over by an abbot or abbess, in contradistinction to cathedral, which is presided over by bishop; and priory, the head of which was a prior or prioress.

Abutment. That part of a pier from which the arch springs.

Abuttals. The boundings of a piece of land on other land, street, river, etc

Acanthus. A plant found in the south of Europe, representations of whose leaves are employed for decorating the Corinthian and Composite capitals. The leaves of the acanthus are used on the bell of the capital, and distinguish the two rich orders from the three others.



ACANTHUS

Acroteria. The small pedestals placed on the extremities and apex of a pediment. They are usually without bases or plinths, and were originally intended to receive statues.

Aile, Aisle. The wings; inward side porticos of a church; the inward latera corridors which enclose the choir, the presbytery, and the body of the church along its sides. Any one of the passages in a church or hall into which the pews or seats open.

Alcove. The original and strict meaning of this word, which is derived from the Spanish *alcoba*, is confined to that part of a bed-chamber in which the bed stands, separated from the other parts of the room by columns or pilasters. It is now commonly used to express any large recess in a room, generally separated by an arch.

Alipterion. In ancient Roman architecture, a room used by bathers fo anointing themselves.

* This Glossary was compiled by Mr. Kidder from various sources, and with th exception of some changes in typographical details to make it conform generally to th matter in the rest of the book it is left as published in the preceding editions.

lmonry. The place or chamber where alms were distributed to the poor in ırches, or other ecclesiastical buildings. At Bishopstone Church, Wiltshire, gland, it is a sort of covered porch attached to the south transept, but not nmunicating with the interior of the church. At Worcester Cathedral, Engd, the alms are said to have been distributed on stone tables, on each side, hin the great porch. In large monastic establishments, as at Westminster, eems to have been a separate building of some importance, either joining the e-house or near it, that the establishment might be disturbed as little as sible.

ltar. In ancient Roman architecture, a place on which offerings or sacris were made to the gods. In Protestant churches, the communion table is en designated as the Altar, and in Roman Catholic churches it is a square le placed at the east end of the church for the celebration of mass.

ltar of Incense. A small table covered with plates of gold on which was ced the smoking censer in the temple at Jerusalem.

ltar-piece. The entire decorations of an altar; a painting placed behind an ar.

ltar-screen. The back of the altar from which the canopy was suspended, l separating the choir from the lady chapel and presbytery. The Altar-screen s generally of stone, and composed of the richest tabernacle work of niches, als, and pedestals, supporting statues of the tutelary saints.

lto-rilievo. High relief. A sculpture, the figures of which project from the face on which they are carved.

mbo. A raised platform, a pulpit, a reading-desk, a marble pulpit — an ong enclosure in ancient churches, resembling in its uses and positions the dern choir.

mbry. A cupboard or closet, frequently found near the altar in ancient ırches to hold sacred utensils.

mbulatory. An alley — a gallery — a cloister.

mphiprostylos. A Grecian temple which has a columned portico on both ls.

mphitheater. A double theater, of an elliptical form on the plan, for the ibition of the ancient gladiatorial fights and other shows. Its arena or pit, in ich those exhibitions took place, was encompassed with seats rising above h other, and the exterior had the accommodation of porticos or arcades for public.

mphora. A Grecian vase with two handles, often seen on medals.

ncones. The consoles or ornaments cut on the key-stones of arches or on sides of door-cases. They are sometimes made use of to support busts or er figures.

ngle-bar. In joinery, an upright bar at the angles of polygonal windows; ıullion.

ngle-capital. In Greek architecture, those Ionic capitals placed on the flank umns of a portico, which have one of their volutes placed horizontally at an le of a hundred and thirty-five degrees with the plane of the frieze.

nnulated Columns. Columns clustered together by rings or bands; much d in English architecture.

nnular Vault. A vault rising from two parallel walls—the vault of a ridor. Same as *Barrel Vault.*

Annulet. A small square molding used to separate others. The fillet separates the flutings of columns is sometimes known by this term.

ANNULET

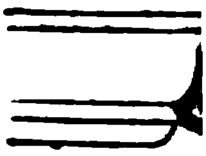
Anta, Antæ. A name given to a pilaster when attached to a wall. Vitruvius calls pilasters *parastatæ* when insulated. They are not usually diminished, and in all Greek examples their capitals are different from those of the columns they accompany.

Antechamber. An apartment preceded by a vestibule and from whic approached another room.

Antechapel. A small chapel forming the entrance to another. There examples at Merton College, Oxford, and at King's College, Cambridge, Engl besides several others. The antechapel to the lady-chapel in cathedral generally called the Presbytery.

Antechoir. The part under the rood loft, between the doors of the d and the outer entrance of the screen, forming a sort of lobby. It is also ca the Fore-choir.

Antefixa. In classical architecture (gargoyles, in Gothic architecture), ornaments of lions' and other heads below the eaves of a temple, through channels in which, usually by the mouth, the water is carried from the eaves. By some this term is applied to the upright ornaments above the eaves in ancient architecture, which hid the ends of the Harmi or joint tiles.



ANTEFIXA

Apophyge. The lowest part of the shaft of an Ionic or Corinthian colu or the highest member of its base if the column be considered as a whole. T Apophyge is the inverted cavetto or concave sweep, on the upper edge of wh the diminishing shaft rests.

Apron. A plain or molded piece of finish below the stool of a window, p on to cover the rough edge of the plastering.

Apse. The semicircular or polygonal termination to the chancel of a chur

Apteral. A temple without columns on the flanks or sides.

Aqueduct. An artificial canal for the conveyance of water, either above under ground. The Roman aqueducts are mostly of the former construction.

Arabesque. A building after the manner of the Arabs. Ornaments used the same people, in which no human or animal figures appear. Arabesque is sometimes improperly used to denote a species of ornaments composed of capricious fantastics and imaginary representations of animals and foliage so much employed by the Romans in the decorations of walls and ceilings.

Arabian Architecture. A style of architecture the rudiments of which appear to have been taken from surrounding nations, the Egyptians, Syrians, Chaldeans, and Persians. The best preserved specimens partake chiefly of the Græco-Roman, Byzantine, and Egyptian. It is supposed that they constructed many of their finest buildings from the ruins of ancient cities.

Aræostyle. That style of building in which the columns are distant from one another from four to five diameters. Strictly speaking, the term should be limited to intercolumniation of four diameters, which is only suited to the Tuscan order.

ARABESQ

Aræosystylos. That style of building in which four columns are used in the space of eight diameters and a half; the central

ercolumniation being three diameters and a half, and the others on each e being only half a diameter, by which arrangement coupled columns are roduced.

Arbores. Large bronze candelabra, in the shape of a tree, placed on the floor ancient churches, so as to appear growing out of it.

Arcade. A range of arches, supported either columns or on piers, and detached or attached the wall.

Arch. In building, a mechanical arrange-nt of building materials arranged in the form a curve, which preserves a given form when isting pressure, and enables them, supported piers or abutments, to carry weights and ist pressure.

ARCADE

Arch-buttress. Sometimes called a flying tress; an arch springing from a buttress or pier.

Architrave. That part of an entablature which rests upon the capital of a umn, and is beneath the frieze.

Architrave Cornice. An entablature consisting of an architrave and cor-, without the intervention of the frieze, sometimes introduced when incon-ient to give the entablature the usual height.

Architrave of a Door. The finished work surrounding the aperture; the er part of the lintel is called the traverse; and the sides, the jambs.

Archives. A repository or closet for the preservation of writings or records.

Archivolt. A collection of members forming the inner contour of an arch, a band or frame adorned with moldings running over the faces or the arch-nes, and bearing upon the imposts.

Area. The superficial contents of any figure; an open space or court within uilding; also, an uncovered space surrounding the foundation walls to give t to the basement.

Arena. The plain space in the middle of the amphitheater or other place of lic resort.

Arris. The meeting of two surfaces producing an angle.

Arsenal. A public storehouse for arms and ammunition.

Artificer, or **Artisan.** A person who works with his hands, and manufac-s any commodity in iron, brass, wood, etc.

Ashlar, or **Ashler.** A facing made of squared stones, or a facing made of slabs, used to cover walls of brick or rubble. *Coursed ashlar* is where the nes run in level courses all around the building, *random ashlar*, where the nes are of different heights, but level beds. Common freestones of small , as they come from the quarry, are also called ashlar.

Asphaltum. A kind of bituminous stone, principally found in the province Neufchatel. Mixed with stone, it forms an excellent cement, incorruptible ir and impenetrable by water.

Astragal. A small semicircular molding, sometimes plain and sometimes mented.

Asymptote. A straight line which continually approaches to a curve with-touching it.

Atlases, or **Atlantes.** Figures or half-figures of men, used instead of c umns or pilasters to support an entablature; called also Telamones.

ATLANTES

Atrium. A court in the interior division of Roman houses.

Attached Columns. Those which project three-fourths of their diameter from the wall.

Attic. A low story above an entablature, or above a cornice which limits the height of the main part of an elevation. Although the term is evidently derived from the Greek, we find nothing exactly answering to it in Greek architecture; but it is very common in both Roman and Italian practice. What are otherwise called tholobates in St. Peter's and St. Paul's Cathedrals are frequently termed attics.

Attic Order. A term used to denote the low pilasters employed in t decoration of an attic story.

Attributes. In painting and sculpture, symbols given to figures and stat to indicate their office and character.

Auditory. In ancient churches, that part of the church where the peo usually stood to be instructed in the Gospel, now called the nave.

Aula. A court or hall in ancient Roman houses.

Aviary. A large apartment for breeding birds.

Axis. The spindle or center of any rotative motion. In a sphere, an im inary line through the center.

Back-choir. A place behind the altar in the principal choir, in which th is, or was, a small altar standing back to back with the former.

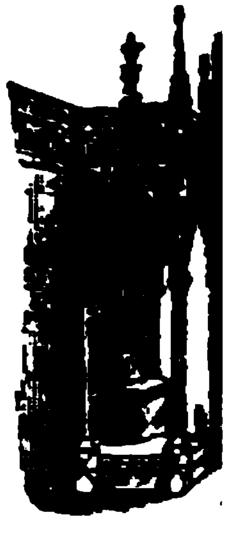
Backing of a Rafter or Rib. The forming of an upper or outer surfa that it may range with the edges of the ribs or rafters on either side.

Backing of a Wall. The rough inner face of a wall; earth deposited beh a retaining wall, etc.

Back of a Window. That piece of wainscoting which is between the bott of the sash frame and the floor.

Balcony. A projection from the face of a wall, supported by columns or c soles, and usually surrounded by a balustrade.

Baldachin. A building in the form of a canopy, supported with columns, a serving as a crown or covering to an altar.



BALDACHI

Baluster. A small pillar or column, supporting a rail, of various forms, used in balustrades.

Baluster Shaft. The shaft dividing a window in Saxon architecture. At St. Albans are some of these shafts, evidently out of the old Saxon church, which have been fixed up with Norman capitals.

Balustrade. A series of balusters connected by a rail.

Band. A sort of flat frieze or fascia running horizontally round a tower or other parts of a building, particularly the base tables in perpendicular work, commonly used with the long shafts characteristic of the thirteenth century. It generally has a bold, projecting molding above

ıd below, and is carved sometimes with foliages, but in general with cusped rcles, or quatrefoils, in which frequently are shields of arms.

Band of a Column. A series of annulets and hollows going round the middle the shafts of columns, and sometimes of the entire pier. They are often beau-fully carved with foliages, etc., as at Amiens. In several cathedrals there are ıgs of bronze apparently covering the junction of the frusta of the columns. : Worcester and Westminster they appear to have been gilt; they are there ore properly called Shaft-rings.

Baptistery. A separate building to contain the font, for the rite of baptism. ıey are frequent on the Continent; that at Rome, near St. John Lateran, and ose at Florence, Pisa, Pavia, etc., are all well-known examples. The only ex-ıples in England are at Cranbrook and Canterbury; the latter, however, is pposed to have been originally part of the treasury.

Barbican. An outwork for the defence of a gate or drawbridge; also, a sort pent-house or construction of timber to shelter warders or sentries from arrows other missiles.

Barge Board. See *Verge Board.*

Bartizan.. A small turret, corbeled out at the angle of a wall or tower, to pro-ct a warder and enable him to see around him. ıey generally are furnished with oylets or arrow-ts.

BARTIZAN

Basement. The lower part of a building, usu-y in part below the grade of the lot or street.

Base Moldings. The moldings immediately ove the plinth of a wall, pillar, or pedestal.

Base of a Column. That part which is between e shaft and the pedestal, or, if there be no pedes-l, between the shaft and the plinth. The Grecian Doric had no base, and the ıscan has only a single torus, or a plinth.

Basilica. A term given by the Greeks and Romans to the public buildings voted to judicial purposes.

Bas-relief. See *Basso-rilievo.*

Basse-cour. A court separated from the principal one, and destined for ıbles, etc.

Basso-rilievo, or **Bas-relief.** The representations of figures projected from background without being detached from it. It is divided into three parts: to-rilievo, when the figure projects more than one-half; Mezzo-rilievo, that in ıich the figure projects one-half; and Basso-rilievo, when the projection of the ıre is less than one-half, as in coins.

Bat. A part of a brick.

Batten. Small scantlings, or small strips of boards, used for various purposes. ıall strips put over the joints of sheathing to keep out the weather.

Batten-door. A door made of sheathing, secured by strips of board, put ssways, and nailed with clinched nails.

Batter. A term used by bricklayers, carpenters, etc., to signify a wall, piece timber, or other material, which does not stand upright, but inclines from you ıen you stand before it; but when, on the contrary, it leans toward you, it is d to overhang.

Battlement. A parapet with a series of notches in it, from which arrows may be shot, or other instruments of defence hurled on besiegers. The raised portions are called merlons; and the notches, embrasures or crenelles. The former were intended to cover the soldier while discharging his weapon through the latter. Their use is of great antiquity; they are found in the sculptures of Nineveh, in the tombs of Egypt, and on the famous François vase, where there is a delineation of the siege of Troy. In ecclesiastical architecture the early battlements have small shallow embrasures at some distance apart. In the Decorated period they are closer together, and deeper, and the moldings on the top of the merlon and bottom of the embrasure are richer. During this period, and the early part of the Perpendicular, the sides or cheeks of the embrasures are perfectly square and plain. In later times the moldings were continued round the sides, as well as at top and bottom, mitring at the angles, as over the doorway of Magdalen College, Oxford, England. The battlements of the Decorated and later periods are often richly ornamented by paneling, as in the last example. In castellated work the merlons are often pierced by narrow arrow-slits. (See *Oylet.*) In South Italy some battlements are found strongly resembling those of old Rome and Pompeii; in the Continental ecclesiastical architecture, the parapets are very rarely embattled.

BATTLEMENT

Bay. Any division or compartment of an arcade, roof, etc. Thus each space from pillar to pillar, in a cathedral, is called a bay, or severy.

Bay Window. Any window projecting outward from the wall of a building, either square or polygonal on plan, and commencing from the ground. If they are carried on projecting corbels, they are called Oriel windows. Their use seems to have been confined to the later periods. In the Tudor and Elizabethan style they are often semicircular in plan, in which case some think it more correct to call them Bow Windows.

Bazaar. A kind of Eastern mart, of Arabic origin.

Bead. A circular molding. When several are joined, it is called Reeding; when flush with the surface, it is called Quirk-bead; and when raised, Cock-bead.

Beam. A piece of timber, iron, stone, or other material, placed horizontally, or nearly so, to support a load over an opening, or from post to post.

Bearing. The portion of a beam, truss, etc., that rests on the supports.

Bearing Wall, or **Partition.** A wall which supports the floors and roofs in a building.

Beaufet, or **Buffet.** A small cupboard, or cabinet, to contain china. It may either be built into a wall, or be a separate piece of furniture.

Bed. In bricklaying and masonry, the horizontal surfaces on which the stones or bricks of walls lie in courses.

Bed of a Slate. The lower side.

Bed Moldings. Those moldings in all the orders between the corona and frieze.

Belfry. Properly speaking, a detached tower or campanile containing bells, as at Evesham, England, but more generally applied to the ringing-room or loft of the tower of a church. See *Tower*.

Bell-cot, Bell-gable, or **Bell-turret.** The place where one or more bells are ıung in chapels, or small churches which have no towers. Bell-cots are some- :imes double, as at Northborough and Coxwell, England; a very common form n France and Switzerland admits of three bells. In these countries, also, they ıre frequently of wood, and attached to the ridge. Those which stand on the gable, dividing the nave from the chancel, are generally called Sanctus Bells. A /ery curious and, it is believed, unique example at Cleves Abbey, England, juts ›ut from the wall. In later times bell-turrets were much ornamented; these are ›ften called Flèches.

Bell of a Capital. In Gothic work, immediately above the necking is a deep, ıollow curve; this is called the bell of a capital. It is often enriched with foli- ıges. It is also applied to the body of the Corinthian and Composite capitals.

Belt. A course of stones or brick projecting from a brick or stone wall, gen- ›rally placed in a line with the sills of the windows; it is either molded, fluted, ›lane, or enriched with patras at regular intervals. Sometimes called Stone ›tring.

Belvedere, or **Look-out.** A turret or lantern raised above the roof of an ›bservatory for the purpose of enjoying a fine prospect.

Bema. The semicircular recess, or hexedra, in the basilica, where the judges at, and where in after-times the altar was placed. It generally is roofed with a ıalf-dome or concha. The seats of the priests were against the wall, looking into he body of the church, that of the bishop being in the center. The bema ; generally ascended by steps, and railed off by cancelli.

Bench Table. The stone seat which runs round the walls of large churches, ınd sometimes round the piers; it very generally is placed in the porches.

Bevel. An instrument for taking angles. One side of a solid body is said to e beveled with respect to another, when the angle contained between those two ides is greater or less than a right angle.

Bezantee. A name given to an ornamental molding much used in the Nor- ıan period, resembling bezants, coins struck in Byzantium.

Billet. A species of ornamented molding much used in Norman, and some- imes in Early English work, like short pieces of stick cut off and arranged alter- ately.

Blocking, or **Blocking-course.** In masonry, a course of stones placed on he top of a cornice crowning the walls.

Bond. In bricklaying and masonry, that connection between bricks or stones ›rmed by lapping them upon one another in carrying up the work, so as to form n inseparable mass of building, by preventing the vertical joints falling over ach other. In brickwork there are several kinds of bond. In common brick alls in every sixth or seventh course the bricks are laid crossways of the wall, alled Headers. In face work, the back of the face brick is clipped so as to get a diagonal course of headers behind. In Old English bond, every alternate ›urse is a header course. In Flemish bond, a header and stretcher alternate each course.

Bond-stones. Stones running through the thickness of the wall at right ıgles to its face, in order to bind it together.

Bond-timbers. Timbers placed in a horizontal direction in the walls of a ick building in tiers, and to which the battens, laths, etc., are secured. In rub- e work, walls are better plugged for this purpose.

Border. Useful ornamental pieces around the edge of anything.

Boss. An ornament, generally carved, forming the key-stone at the intersetion of the ribs of a groined vault. Early Norman vaults have no bosses. The carving is generally foliage, and resembles that of the period in capitals, etc. Sometimes they have human heads, as at Notre Dame at Paris, and sometimes grotesque figures. In Later Gothic vaulting there are bosses at every intersection.

Boutell. The mediæval term for a round molding, or torus. When it follows a curve, as round a bench end, it is called a Roving Boutell.

Bow. Any projecting part of a building in the form of an arc of a circle. A bow, however, is sometimes polygonal.

Bow Window. A window placed in the bow of a building.

Brace. In carpentry, an inclined piece of timber, used in trussed partitions or in framed roofs, in order to form a triangle, and thereby stiffen the framing. When a brace is used by way of support to a rafter, it is called a strut. Braces in partitions and span-roofs are, or always should be, disposed in pairs, and introduced in opposite directions.

Brace Mold. [{] Two ressaunts or ogees united together like a brace in printing, sometimes with a small bead between them.

Bracket. A projecting ornament carrying a cornice. Those which support vaulting shafts or cross springers of a roof are more generally called Corbels.

Break. Any projection from the general surface of a building.

Breaking Joint. The arrangement of stones or bricks so as not to allow two joints to come immediately over each other. See *Bond*.

Breast of a Window. The masonry forming the back of the recess and the parapet under the window-sill.

CROSS-BRIDGING

Bressummer. A lintel, beam, or iron tie, intended to carry an external wall and itself supported by piers or posts; used principally over shop windows. This term is now seldom used, the word *beam*, or *girder*, taking its place.

Bridging. A method of stiffening floor joist and partition studs, by cutting pieces in between. Cross bridging of floor joist is illustrated in cut.

Bulwark. In ancient fortification, nearly the same as Bastion in modern.

Burse, or **Bourse.** A public edifice for the assembly of merchant traders; an exchange.

Bust. In sculpture, that portion of the human figure which comprises the head, neck, and shoulders.

BUTTRESS

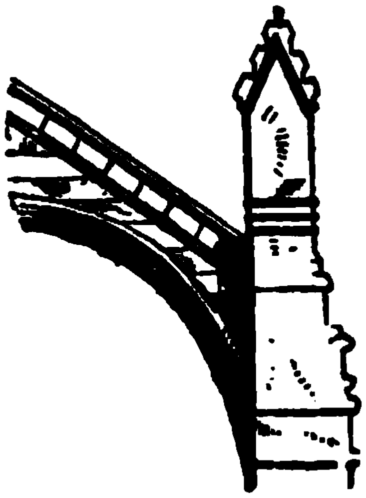
Buttery. A store-room for provisions.

Butt-joint. Where the ends of two pieces of timber or molding butt together.

Buttress. Masonry projecting from a wall, and intended to strengthen the same against the thrust of a roof or vault. Buttresses are no doubt derived from the classic pilasters which serve to strengthen walls where there is a pressure of a girder or roof-timber. In very early work they have little projection, and, in fact, are "strippilasters." In Norman work they are wider, with very little projection, and generally stop under a cornice or corbel table. Early English buttresses project considerably, sometimes with deep sloping weatherings in several

stages, and sometimes with gabled heads. Sometimes they are chamfered, and sometimes the angles have jamb shafts. At Wells and Salisbury, England, they are richly ornamented with canopies and statues. In the Decorated period they became richly paneled in stages, and often finish with niches and statues and elegantly carved and crocketed gablets, as at York, England. In the Perpendicular period the weatherings became waved, and they frequently terminate with niches and pinnacles.

Buttress, Flying. A detached buttress or pier of masonry at some distance from a wall, and connected therewith by an arch or portion of an arch, so as to discharge the thrust of a roof or vault on some strong point.



FLYING BUTTRESS

Buttress Shafts. Slender columns at the angle of buttresses, chiefly used in the Early English period.

Byzantine Architecture. A style developed in the Byzantine Empire. The capitals of the pillars are of endless variety and full of invention; some are founded on the Greek Corinthian, some resemble the Norman and the Lombard style, and are so varied that no two sides of the same capital are alike. They are comprised under the style Romanesque, which comprehends the round-arch style. Byzantine architecture reached its height in the Church of St. Sophia at Constantinople.

Cabinet. A highly ornamented kind of buffet or chest of drawers set apart for the preservation of things of value.

Cabling. The flutes of columns are said to be cabled when they are partly occupied by solid convex masses, or appear to be refilled with cylinders after they had been formed.

Caduceus. Mercury's rod, a wand entwined by two serpents and surmounted by two wings. The rod represents power; the serpents, wisdom; and the wings, diligence and activity.

CADUCEUS

Caisson. A panel sunk below the surface in flat or vaulted ceilings. See *Cassoon*

Caisson. In bridge building, a chest or vessel in which the piers of a bridge are built, gradually sinking as the work advances till its bottom comes in contact with the bed of the river, and then the sides are disengaged, being so constructed as to allow of their being thus detached without injury to its floor or bottom.

Caliber, or **Caliper.** The diameter of any round body; the width of the mouth of a piece of ordnance.

Camber. In carpentry, the convexity of a beam upon the surface, in order to prevent its becoming concave by its own weight, or by the burden it may have to sustain.

Campanile. A name given in Italy to the bell-tower of a town-hall or church. In that country this is almost always detached from the latter.

Candelabrum. Stand or support on which the ancients placed their lamps. Candelabra were made in a variety of shapes and with much taste and elegance. The term is also used to denote a tall ornamental candlestick with several arms, or a bracket with arms for candles.

Canopy. The upper part or cover of a niche, or the projection or ornament over an altar, seat, or tomb. The word is supposed to be derived from cono-

peum, the gauze covering over a bed to keep off the gnats; a mosquito curtain. Early English canopies are generally simple, with trefoiled or cinque-foiled heads, but in the later styles they are very rich, and divided into compartments with pendants, knots, pinnacles, etc. The triangular arrangement over an Early English and Decorated doorway is often called a canopy. The triangular canopies in the North of Italy are peculiar. Those in England are generally part of the arrangement of the arch moldings of the door, and form, as it were, the hood-molds to them, as at York. The former are above and independent of the door moldings, and frequently support an arch with a tympanum, above which is a triangular canopy, as in the Duomo at Florence. Sometimes the canopy and arch project from the wall, and are carried on small jamb shafts, as at San Pietro Martiro at Verona. Canopies are often used over windows, as at York Minster over the great west window, and lower tiers in the towers. These are triangular, while the upper windows in the towers have ogee canopies.

Capital. The upper part of a column, pilaster, pier, etc. Capitals have been used in every style down to the present time. That mostly used by the Egyptians was bell-shaped, with or without ornaments. The Persians used the double-headed bell, forming a kind of bracket capital. The Assyrians apparently made use of the Ionic and Corinthian, which were developed by the Greeks, Romans and Italians into their present well-known forms. The Doric was apparently an invention or adaptation by the Greeks, and was altered by the Romans and Italians. But in all these examples, both ancient and modern, the capitals of an order are all of the same form throughout the same building, so that if one be seen the form of all the others is known. The Romanesque architects altered all this, and in the carving of their capitals often introduced such figures and emblems as helped to tell the story of their building. Another form was introduced by them in the curtain capital, rude at first, but afterward highly decorated. It evidently took its origin from the cutting off of the lower angles of a square block, and then rounding them off. The process may be distinctly seen, in its several stages, in Mayence Cathedral. But this form of capital was more fully developed by the Normans, with whom it became a marked feature. In the early English capitals a peculiar flower of three or more lobes was used spreading from the necking upward in most graceful forms. In Decorated and Perpendicular styles this was abandoned in favor of more realistic forms of crumpled leaves, enclosing the bell like a wreath. In each style bold abacus moldings were always used, whether with or without foliage.

Caravansary. A huge, square building, or inn, in the East, for the reception of travelers and lodging of caravans.

Carriage. The timber or iron joist which supports the steps of a wooden stair.

CARYATID

Carton, or Cartoon. A design made on strong paper, to be transferred on the fresh plaster wall to be afterward painted in fresco; also, a colored design for working in mosaic tapestry.

Cartouche. An ornament which like an escutcheon, a shield or an oval or oblong panel has the central part plain, and usually slightly convex, to receive an inscription, armorial bearings, or an ornamental or significant piece of painting or sculpture. Frequently used in French Renaissance and Modern Architecture.

Caryatides. Human female figures used as piers, columns, or supports. *Caryatic* is applied to the human figure generally, when used in the manner of caryatides.

Cased. Covered with other materials, generally of a better quality.

Casement. A glass frame which is made to open by turning on hinges fixed to its vertical edges.

Cassoon, or Caisson. A deep panel or coffer in a soffit or ceiling. This rm is sometimes written in the French form, *caisson;* sometimes derived irectly from the Italian *cassone,* the augmentative of cassa, a chest or coffer.

Cast. A term used in sculpture for the impression of any figure taken in laster of Paris, wax, or other substances.

Catacombs. Subterranean places for burying the dead. Those of Egypt, nd near Rome, are believed to be the most important.

Catafalco. An ornamental scaffold used in funeral solemnities.

Cathedral. The principal church, where the bishop has his seat as diocesan.

Cauliculus. The inner scroll of the Corinthian capital. It is not uncommon, owever, to apply this term to the larger scrolls or volutes also.

Causeway. A raised or paved way.

Cavetto. A concave ornamental molding, opposed in effect to the ovolo — ne quadrant of a circle.

Ceiling. That covering of a room which hides the joists of the floor above, the rafters of the roof Most European churches either have open roofs, or re groined in stone. At Peterborough and St. Albans, England, there are very d flat ceilings of boards curiously painted. In later times the boarded ceilings, nd, in fact, some of those of plaster, have molded ribs, locked with bosses at ne intersection, and are sometimes elaborately carved. In many English hurches there are ceilings formed of oak ribs, filled in at the spandrels ith narrow, thin pieces of board, in exact imitation of stone groining. In ne Elizabethan and subsequent periods the ceilings are enriched with ost elaborate ornaments in stucco. Matched and beaded boards, planed nd smoothed, used for wainscoting. In the New England States it is called heathing.

Cenotaph. An honorary tomb or monument, distinguished from monuments being empty, the individual it is to memorialize having received interment sewhere.

Centaur. A poetical imaginary being of heathen mythology, half-man and alf-horse.

Centring. In building, the frames on which an arch is turned.

Chamfer, Champfer, or Chaumfer. When the edge or arris of any work is ut off at an angle of 45° in a small degree, it is said to be chamfered; if a large scale, it is said to be a canted corner. The chamfer is much used in ediæval work, and is sometimes plain, sometimes hollowed out, and sometimes olded.

Chamfer Stop. Chamfers sometimes simply run into the arris by a plane ce; more commonly they are first stopped by some ornament, as by a bead; ey are sometimes terminated by trefoils, or cinque-foils, double or single, and general form very pleasing features in mediæval architecture.

Chancel. A place separated from the rest of a church by a screen. The word now generally used to signify the portion of an Episcopal or Catholic church ontaining the altar and communion table.

Chantry. A small chapel, generally built out from a church. They generally ontain a founder's tomb, and are often endowed places where masses might

be said for his soul. The officiator, or mass priest, being often unconnected with the parochial clergy. The chantry has generally an entrance from the outside.

Chapel. A small, detached building used as a substitute for a church in a large parish; an apartment in any large building, a palace, a nobleman's house, a hospital or prison, used for public worship; or an attached building running out of and forming part of a large church, generally dedicated to different saints, each having its own altar, piscina, etc., and screened off from the body of the building.

Chapter House. The chamber in which the chapter or heads of the monastic bodies assembled to transact business. They are of various forms; some are oblong apartments, some octagonal, and some circular.

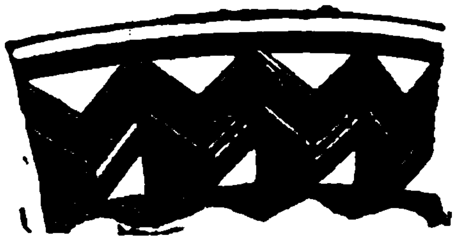
Chaptrel. In Gothic architecture, the capital of a pier or column which receives an arch.

CHAPTREL

Charnel House. A place for depositing the bones which might be thrown up in digging graves. Sometimes it was a portion of the crypt; sometimes it was a separate building in the church-yard; sometimes chantry chapels were attached to these buildings. M. Viollet-le-Duc has given two very curious examples of *ossuaires* — one from Fleurance, the other from Faouet.

Cherub — Gothic. A representation of an infant's head joined to two wings, used in the churches on key-stones of arches and corbels.

Chevron — Gothic. An ornament turning this and that way, like a zigzag, or letter Z.



CHEVRON

Chiaro-oscuro. The effects of light and shade in a picture.

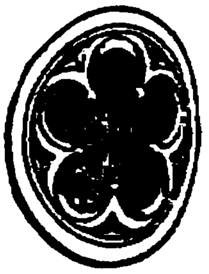
Choir. That part of a church or monastery where the breviary service, or "horæ," is chanted.

Church. A building for the performance of public worship. The first churches were built on the plan of the ancient basilicæ, and afterward on the plan of a cross: a church is said to be in Greek cross when the length of the transverse is equal to that of the nave; in Latin cross, when the nave is longer than the transverse part; in rotundo, when it is a perfect circle; simple, when it has only a nave and choir; with aisles, when it has a row of porticos in form of vaulted galleries, with chapels in its circumference.

Ciborium. A tabernacle or vaulted canopy supported on shafts standing over the high altar.

Cincture. A ring, list, or fillet at the top and bottom of a column, serving to divide the shaft of the column from its capital and base.

Cinque-foil. A sinking or perforation, like a flower, of five points or leaves, as a quatre-foil is of four. The points are sometimes in a circle, and sometimes form the cusping of a head.



CINQUE-FOIL

Civic Crown. A garland of oak-leaves and acorns, given as honorary distinction among the Romans to such as had preserved the life of a fellow-citizen.

Clere-story, Clear-story. When the middle of the nave of a church rises bove the aisles and is pierced with indows, the upper story is thus illed. Sometimes these windows e very small, being mere quatreils, or spherical triangles. In large uildings, however, they are importunt objects both for beauty and tility. The window of the clerecories of Norman work, even in large hurches, are of less importance than 1 the later styles. In Early English ney became larger; and in the Decoated they are more important still, eing lengthened as the triforium iminishes. In Perpendicular work he latter often disappears altogether, nd in many later churches the clerestories are close ranges of windows. 'he word *clere-story* is also used to enote a similar method of lighting ther buildings besides churches, especially factories, depots, sheds, etc.

Bath Abbey

FLYING BUTTRESS AND CLERE-STORY

A, buttress with pinnacle; B, flying buttress supporting clere-story; C, vaulted roof of aisle; D D, pier dividing nave from aisle; E, vaulted roof of nave.

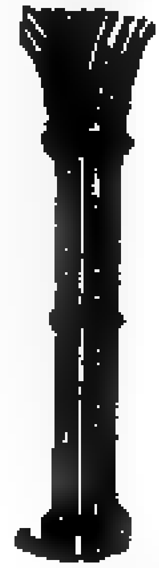
Cloister. An enclosed square, like he atrium of a Roman house, with a alk or ambulatory around, sheltered y a roof, generally groined, and by racery windows, which were more r less glazed.

Close. The precinct of a cathedral r abbey. Sometimes the walls are raceable, but now generally the oundary is only known by tradion.

Close String, or **Box String.** A ıethod of finishing the outer edge of airs, by building up a sort of curb ring on which the balusters set, nd the treads and risers stop against it.

Clustered. In architecture, the coalition of several members 'hich penetrate each other.

Clustered Column. Several slender pillars attached to each ther so as to form one. The term is used in Roman architecture denote two or four columns which appear to intersect each other the angle of a building to answer at each return.



CLUSTERED COLUMN

Coat. A thickness or covering of paint, plaster, or other work, one at one time. The first coat of plastering is called the scratch at, the second coat (when there are three coats) is called the brown at, and the last coat is variously known as the slipped coat, imcoat, or white coat. It varies in composition in different calities.

Coffer. A deep panel in a ceiling.

Coffer Dam. A frame used in the building of a bridge in deep water similar to a caisson.

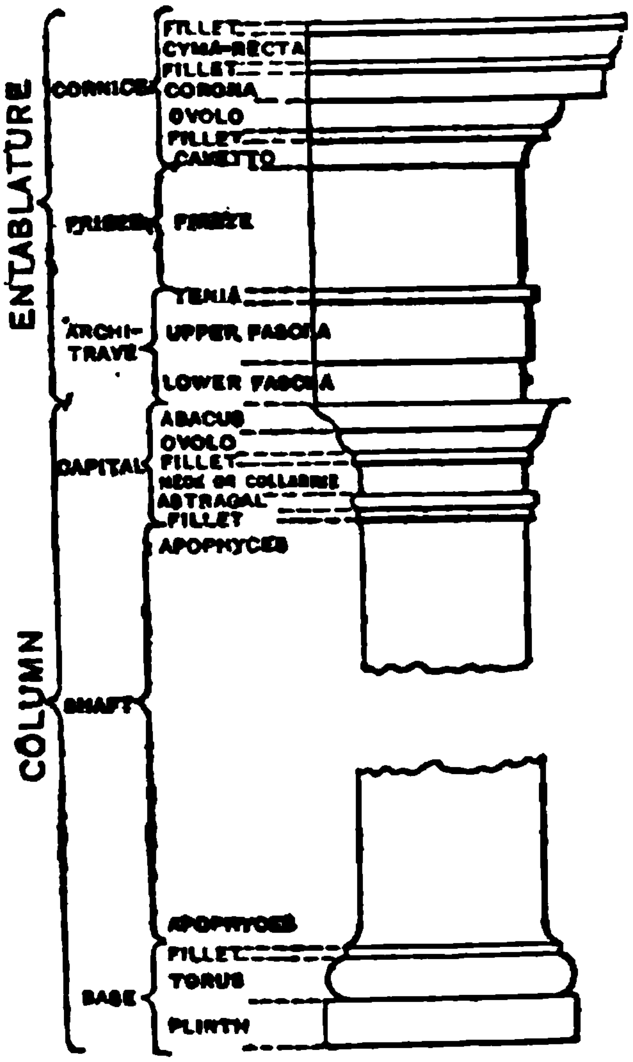
Collar Beam. A beam above the lower ends of the rafters, and spiked to them.

Colonnade. A row of columns. The colonnade is termed, according to the number of columns which support the entablature: Tetrastyle, when there are four; hexastyle, when six; octostyle, when eight, etc. When in front of a building they are termed porticos; when surrounding a building, peristyle; and when double or more, polystyle.

Colosseum, or Coliseum. The immense amphitheater built at Rome by Flavius Vespasian, A D. 72, after his return from his victories over the Jews. It would contain ninety thousand persons sitting, and twenty thousand more standing. The name is now employed to denote an unusually large audience building, generally of a temporary nature.

Colossus. The name of a brazen statue which was erected at the entrance of the harbor at Rhodes, one hundred and five feet in height. Vessels could sail between its legs.

Column. A round pillar. The parts are the base, on which it rests; its body, called the shaft; and the head, called the capital. The capital finishes with a horizontal table, called the abacus, and the base commonly stands on another, called the plinth. Columns may be either insulated or attached. They are said to be attached or engaged when they form part of a wall, projecting one-half or more, but not the whole, of their substance.



SECTION OF COLUMN AND ENTABLATURE

(Divided according to the Tuscan Order)

Common. A line, angle, surface, etc., which belongs equally to several objects. Common centring is a centring without trusses, having a tie beam at bottom. Common joists are the beams in naked flooring to which the joists are fixed. Common rafters in a roof are those to which the laths are attached.

Composite Arch. Is the pointed or lancet arch.

Composite Order. The most elaborate of the orders of classical architecture.

Compound Arch. A usual form of medieval arch, which may be resolved into a number of concentric archways, successively placed within and behind each other.

Conduit. A long narrow passage between two walls or underground for secret communication between different apartments; also, a canal or pipe for the conveyance of water.

Confessional. The seat where a priest or confessor sits to hear confessions

Conge. Another name for the echinus or quarter round.

Conservatory. A building for the protection and rearing of tender plants, ften attached to a house as an apartment. Also, a public place of instruction, esigned to preserve and perfect the knowledge of some branch of learning or he fine arts; as, a *conservatory* of music.

Consistory. The judicial hall of the College of Cardinals at Rome.

Consol, or Console. A bracket or truss, generally with scrolls or volutes at he two ends, of unequal size and contrasted, but onnected by a flowing line from the back of the pper one to the inner convolving face of the lower.

CONSOLES

Coping. The capping or covering of a wall. This of stone, weathered to throw off the wet. In Noran times, as far as can be judged from the little there left, it was generally plain and flat, and projected ver the wall with a floating to form a drip. Afterard it assumed a torus or bowtell at the top, and beame deeper, and in the Decorated period there were enerally several sets-off. The copings in the Perpendicular period assumed omething of the wavy section of the buttress caps, and mitred round the sides f the embrasure, as well as the top and bottom.

Corbel. The name, in medieval architecture, for a piece of stone jutting out f a wall to carry any superincumbent weight. A piece of timber projecting in he same way was called a tassel or a bragger. Thus, the carved ornaments from hich the vaulting shafts spring at Lincoln are corbels. Norman corbels are enerally plain. In the Early English period they are sometimes elaborately arved. They sometimes end with a point, apparently growing into the wall, r forming a knot, and often are supported by angles and other figures. In the ater periods the foliage or ornaments resemble those in the capitals. In modern rchitecture, a short piece of stone or wood projecting from a wall to form a upport, generally ornamented.

Corbel Out. To build out one or more courses of brick or stone from the face f a wall, to form a support for timbers.

Corbel Table. A projecting cornice or parapet, supported by a range of orbels a short distance apart, which carry a molding, above which is a plain iece of projecting wall forming a parapet, and covered by a coping. Sometimes mall arches are thrown across from corbel to corbel, to carry the projection.

Cornice. The projection at the top of a wall finished by a blocking-course, ommon in classic architecture. In Norman times, the wall finished with a corel table, which carried a portion of plain projecting work, which was finished y a coping, and the whole formed a parapet. In Early English times the paraet was much the same, but the work was executed in a much better way, espeially the small arches connecting the corbels. In the Decorated period the corbel able was nearly abandoned, and a large hollow, with one or two subordinate oldings, substituted; this is sometimes filled with the ball-flowers, and someimes with running foliages. In the Perpendicular style the parapet frequently lid not project beyond the wall-line below; the molding then became a string though often improperly called a cornice), and was ornamented by a quatre-foil, r small rosettes, set at equal intervals immediately under the battlements. In nany French examples the molded string is very bold, and enriched with foliage rnaments

Corona. The brow of the cornice which projects over the bed moldings to throw off the water.

Corridor. A long gallery or passage in a mansion connecting various apartments and running round a quadrangle. Any long passage-way in a building.

Countersink. To make a cavity for the reception of a plate of iron, or the head of a screw or bolt, so that it shall not project beyond the face of the work.

Coupled Columns. Columns arranged in pairs.

Course. A continued layer of bricks or stones in buildings; the term is also applicable to slates, shingles, etc.

Court. An open area behind a house, or in the center of a building and the wings. Courts admit of the most elegant ornamentations, such as arcades, etc.

Cove — Coving. The molding called the cavetto, or the scotia inverted, on a large scale, and not as a mere molding in the composition of a cornice, is called a cove or a coving.

Cove-bracketing. The wooden skeleton mold or framing of a cove, applied chiefly to the bracketing of a cove ceiling.

Cove Ceiling. A ceiling springing from the walls with a curve.

Coved and Flat Ceiling. A ceiling in which the section is the quadrant of a circle, rising from the walls and intersecting in a flat surface.

Cradling. Timber work for sustaining the lath and plaster of vaulted ceilings.

Cresting. An ornamental finish in the wall or ridge of a building, which is common on the Continent of Europe. An example occurs at Exeter Cathedral, the ridge of which is ornamented with a range of small fleurs-de-lis in lead.

Crocket. An ornament running up the sides of gablets, hood-molds, pinnacles, spires; generally, a winding stem like a creeping plant, with flowers or leaves projecting at intervals, and terminating in a finial.

CROCKET

Cross. This religious symbol is almost always placed on the ends of gables, the summit of spires, and other conspicuous places of old churches. In early times it was generally very plain, often a simple cross in a circle. Sometimes they take the form of a light cross, crosslet, or a cross in a square. In the Decorated and later styles they became richly floriated, and assumed an endless variety of forms. Of memorial crosses the finest examples are the Eleanor crosses, erected by Edward I. Of these a few yet remain, one of which has recently been reërected at Charing Cross. Preaching crosses were often set up by the wayside as stations for preaching; the most noted is that in front of St. Paul's, England. The finest remaining sepulchral crosses are the old elaborately carved examples found in Ireland.

Cross-aisle. An old name for a transept.

Cross-springer. The transverse ribs of a vault.

Cross-vaulting. A common name given to groins and cylindrical vaults.

Crown. In architecture the uppermost member of the cornice; called also Corona and Larmier.

Crypt. A vaulted apartment of greater or less size, usually under the choir.

Cupola. A small room, either circular or polygonal, standing on the top of a dome. By some it is called a Lantern.

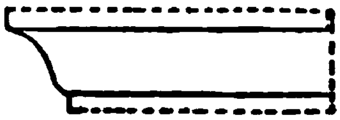
:urb **Roof,** or **Mansard Roof.** A roof formed of four contiguous planes, h two having an external inclination.

:urtail **Step.** The first step in a stair, which is generally finished in the form a scroll.

:**usp.** The point where the foliations of tracery intersect. The earliest ample in England of a plain cusp is probably that at Pythagoras School, at mbridge, of an ornamental cusp, at Ely Cathedral, where a small roll, with a ette at the end, is formed at the termination of a cusp. In the later styles the minations of the cusps were more richly decorated; they also sometimes minate not only in leaves or foliages, but in rosettes, heads, and other fanciful aments.

Cyclostyle. A structure composed of a circular range of columns without a e is cyclostylar; with a core, the range would be a peristyle. This is the spe-s of edifice called by Vitruvius monopteral.

Cyma. The name of a molding of very frequent use. It is a simple, waved e, concave at one end and convex at the other, like an lic *f*. When the concave part is uppermost it is called yma recta, but if the convexity appear above, and the acavity below, it is then a cyma reversa.



CYMA RECTA

Cymatium. When the crowning molding of an en-blature is of the cyma form, it is termed the Cyma-m.

CYMA REVERSA

Cyrtostyle. A circular projecting portico. Such are ose of the transept entrances to St. Paul's Cathedral, London.

Dado, or **Die.** The vertical face of an insulated pedestal between the base d cornice, or surbase. It is extended also to the similar part of all stereobates ich are arranged like pedestals in Roman and Italian architecture.

Dais. A part of the floor at the end of a mediæval hall, raised a step above e rest of the floor. On this the lord of the mansion dined with his friends at e great table, apart from the retainers and servants. In mediæval halls there is generally a deep recessed bay window at one or at each end of the dais, pposed to be for retirement, or greater privacy than the open hall could afford. France the word is understood as a canopy or hanging over a seat; probably e name was given from the fact that the seats of great men were then sur-ounted by such an ornament.

Darby. A flat tool used by plasterers in working, especially on ceilings. It generally about seven inches wide and forty-two inches long, with two handles the back.

Decastyle. A portico of ten columns in front.

Decorated Style. The second stage of the Pointed or Gothic style of archi-cture, considered the most complete and perfect development of Gothic archi-cture, the best examples of which are found in England.

Demi-metope. The half of a metope, which is found at the retiring or pro-cting angles of a Doric frieze.

Dentil. The cogged or toothed member, common in the bed-mold of a Corin-ian entablature, is said to be dentiled, and each cog or tooth is called a dentil.

Depressed Arches, or **Drop Arches.** Those of less pitch than the equilateral.

Design. The plans, elevations, sections, and whatever other drawings may e necessary for an edifice, exhibit the design, the term plan having a restricted oplication to a technical portion of the design.

Detail. As used by architects, detail means the smaller parts into which composition may be divided. It is applied generally to moldings and other enrichments, and again to their minutiæ.

Diameter. The line in a circle passing through its center, or thickest part, which gives the measure proportioning the intercolumniation in some of the orders.

Diameters. The diameters of the lower and upper ends of the shaft of a column are called its inferior and superior diameters, respectively; the former is the greatest, the latter the least diameter of the shaft.

Diaper. A method of decorating a wall, panel, stained glass, or any plain surface, by covering it with a continuous design of flowers, rosettes, etc., either in squares or lozenges, or some geometrical form resembling the pattern of a diapered table-cloth, from which, in fact, the name is supposed by some to have been derived.

Diastyle. A spacious intercolumniation, to which three diameters are assigned.

Dipteros. A double-winged temple. The Greeks are said to have constructed temples with two ranges of columns all around, which were called dipteroi. A portico projecting two columns and their interspaces is of dipteral or pseudo-dipteral arrangement.

Discharging Arch. An arch over the opening of a door or window, to discharge or relieve the superincumbent weight from pressing on the lintel.

Distemper. Term applied to painting with colors mixed with size or other glutinous substance. All the cartoons of the ancients, previous to the year 1410, are said to be done in distemper.

Distyle. A portico of two columns. This is not generally applied to the mere porch with two columns, but to describe a portico with two columns in antis.

Ditriglyph. An intercolumniation in the Doric order, of two triglyphs.

Dodecastyle. A portico of twelve columns in front. The lower one of the west front of St. Paul's Cathedral, London, is of twelve columns, but they are coupled, making the arrangement pseudo-dodecastyle. The Chamber of Deputies in Paris has a true dodecastyle.

Dog-tooth. A favorite enrichment used from the latter part of the Norman period to the early part of the Decorated. It is in the form of a four-leaved flower, the center of which projects, and probably was named from its resemblance to the dog-toothed violet.

Dome. A cupola or inverted cup on a building. The application of this term to its generally received purpose is from the Italian custom of calling an archepiscopal church, by way of eminence, Il Duomo, the temple; for to one of that rank, the Cathedral of Florence, the cupola was first applied in modern practice. The Italians themselves never call a cupola a dome; it is on this side of the Alps the application has arisen, from the circumstance, it would appear, that the Italians use the term with reference to those structures whose most distinguishing feature is the cupola, tholus, or (as we now call it) dome.

Domestic Architecture. That branch which relates to private buildings.

Donjon. The principal tower of a castle, generally containing the prison.

Door Frame. The surrounding case into and out of which the door shuts and opens. It consists of two upright pieces, called jambs, and a head, generally fixed together by mortices and tenons, and wrought, rebated, and beaded.

Doric Order. The oldest of the three orders of Grecian architecture.

Dormer Window. A window belonging to a room in a roof, which conse- uently projects from it with a valley gutter on each side. They are said not to e earlier than the fourteenth century. In Germany there are often several rows f dormers, one above the other. In Italian Gothic they are very rare; in fact, e former have an unusually steep roof, while in the latter country, where the :alian tile is used, the roofs are rather flat.

Dormitory. A room, suite of rooms, or building used to sleep in. The name as first applied to the place where the monks slept at night. It was sometimes ne long room like a barrack, and sometimes divided into a succession of small ambers or cells. The dormitory was generally on the first floor, and connected ith the church, so that it was not necessary to go out-of-doors to attend the octurnal services. In the large houses of the Perpendicular period, and also in me of the Elizabethan, the entire upper story in the roof formed one large partment, said to have been a place for exercise in wet weather, and also for a ormitory for the retainers of the household, or those of visitors.

Double Vault. Formed by a duplicate wall; wine cellars are sometimes so rmed.

Dovetailing. In carpentry and joinery, the method of fastening boards or ther timbers together, by letting one piece into another in the form of the xpanded tail of a dove.

Dowel. A pin let into two pieces of wood or stone, where they are joined gether. A piece of wood driven into a wall so that other pieces may be nailed it. This is also called plugging.

Draw-bridge. A bridge made to draw up or let down, much used in fortified laces. In navigable rivers, the arch over the deepest channel is made to draw r revolve, in order to let the masts of ships pass through.

Drawing-room. A room appropriated for the reception of company; a room which company withdraws from the dining-room.

Dresser. A cupboard or set of shelves to receive dishes and cooking utensils.

Dressing. Is the operation of squaring and smoothing stones for building; lso applied to smoothing lumber.

Dressing-room. An apartment appropriated for dressing the person.

Drip. A name given to the member of a cornice which has a projection eyond the other parts for throwing off water by small portions, drop by drop. t is also called Larmier.

Drip-stone. The label molding which serves on a canopy for an opening, nd to throw off the rain. It is also called Weather Molding.

Drop-scene. A curtain suspended by pulleys, which descends or drops in ont of the stage in a theater.

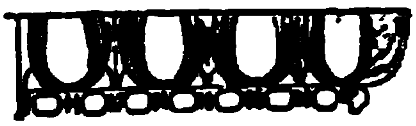
Drum. The upright part of a cupola over a dome; also, the solid part or vase f the Corinthian and Composite capitals.

Dry-rot. A rapid decay of timber, by which its substance is converted into dry powder, which issues from minute cavities resembling the borings of orms.

Dungeon. The prison in a castle keep, so called because the Norman name r the latter is donjon, and the dungeons, or prisons, are generally in its lowest ory.

Dwarf Wall. The walls enclosing courts above which are railings of iron; w walls, in general, receive this name.

Eaves. In slating and shingling, the margin or lower part of the slating hanging over the wall, to throw the water off from the masonry or brickwork.



ECHINUS

Echinus. A molding of eccentric curve, generally cut (when it is carved) into the forms of eggs and anchors alternating, whence the molding is called by the name of the more conspicuous. It is the same as Ovolo.

Edifice. Is synonymous with the terms building, fabric, erection, but is more strictly applicable to architecture distinguished for size, dignity, and grandeur.

Efflorescence. In architecture, the formation of a whitish loose powder, or crust, on the surface of stone or brick walls.

Egyptian Architecture. The earliest civilization and cultivation of the arts was in Upper Egypt. The most remarkable and most ancient monuments of the Egyptians, with the exception of the pyramids, are nearly all included in Upper Egypt. The buildings of Egypt are characterized by solidity and massiveness of construction, originality of conception, and boldness of form. The walls, the pillars, and the most sacred places of their religious buildings were ornamented with hieroglyphics and symbolical figures, while the ceilings of the porticos exhibited zodiacs and celestial planispheres. The temples of Egypt were generally without roofs, and, consequently, the interior colonnades had no pediments, supporting merely an entablature, composed of only architrave, frieze, and cornice, formed of immense blocks united without cement and ornamented with hieroglyphics.

Element. The outline of the design of a Decorated window, on which the centers for the tracery are formed. These centers will all be found to fall on points which, in some way or other, will be equimultiples of parts of the openings. To draw tracery well, or understand even the principles of its composition, much attention should be given to the study of the element.

Elevation. The front façade, as the French term it, of a structure; a geometrical drawing of the external upright parts of a building.

Embattlement. An indented parapet; battlement.

Emblazon. To adorn with figures of heraldry, or ensigns armorial.

Embossing. Sculpture in rilievo, the figures standing partly out from the plane.

Embrasure. The opening in a battlement between the two raised solid portions or merlons, sometimes called a crenelle.

Encaustic. Pertaining to the art of burning in colors, applied to painting on glass, porcelain, or tiles, where colors are fixed by heat; hence, encaustic tiles, bricks, etc.

Engaged Columns. Are those attached to, or built into walls or piers, a portion being concealed.

Enrichment. The addition of ornament, carving, etc., to plain work; decoration; embellishment.

Ensemble. Means the whole work or composition considered together, and not in parts.

Entablature. The assemblage of parts supported by the column. It consists of three parts: the architrave, frieze, and cornice.

Entail. In Gothic architecture, delicate carving.

Entasis. The swelling of a column, etc. In mediæval architecture, some pires, particularly those called "broach spires," have a slight swelling in the ides, but no more than to make them look straight; for, from a particular deceptio visus," that which is quite straight, when viewed at a height, looks ollow.

Entry. A hall without stairs or vestibule.

Epistyle. This term may with propriety be applied to the whole entablature, ith which it is synonymous; but it is restricted in use to the architrave, or west member of the entablature.

Escutcheon. (Her.) The field or ground on which a coat-of-arms is repre- nted. (Arch.) The shields used on tombs, in the spandrels of doors, or in ring-courses; also, the ornamented plates from the centre of which door rings, nockers, etc., are suspended, or which protect the wood of the key-hole from e wear of the key. In mediæval times these were often worked in a very autiful manner.

Etching. A mode of engraving on glass or metal (generally copper) by means lines, eaten in or corroded by means of some strong acid.

Eustyle. A species of intercolumniation to which a proportion of two diam- ers and a quarter is assigned. This term, together with the others of similar port — pycnostyle, systyle, diastyle, and aræostyle — referring to the distance columns from one another in composition, is from Vitruvius, who assigns to ch the space it is to express. It will be seen, however, by reference to them dividually, that the words themselves, though perhaps sufficiently applic- le convey no idea of an exactly defined space, and, by reference to the lumnar structures of the ancients, that no attention was paid by them to ch limitations. It follows, then, that the proportions assigned to each are rely conventional, and may or may not be attended to without vitiating the wer of applying the terms. Eustyle means the best or most beautiful ar- ngement; but, as the effect of a columnar composition depends on many ings besides the diameter of the columns, the same proportioned inter- lumniation would look well or ill according to those other circumstances, that the limitation of Eustyle to two diameters and a quarter is absurd.

Extrados. The exterior or convex curve forming the upper line of the arch nes; the term is opposed to the intrados, or concave side.

Eye of a Dome. The aperture at its summit.

Eye of a Volute. The circle in its center.

Façade, or **Face.** The whole exterior side of a building that can be seen at e view; strictly speaking, the principal front.

Face Mold. The pattern for marking the plank or board out of which namental hand-railings for stairs and other works are cut.

Fan Tracery. The very complicated mode of roofing used in the Perpen- cular style, in which the vault is covered by ribs and veins of tracery.

Fascia. A flat, broad member in the entablature of columns or other parts of ildings, but of small projection. The architraves in some of the orders are mposed of three bands, or fasciæ; the Tuscan and the Doric ought to have only e. Ornamental projections from the walls of brick buildings over any of the ndows, except the uppermost, are called Fasciæ.

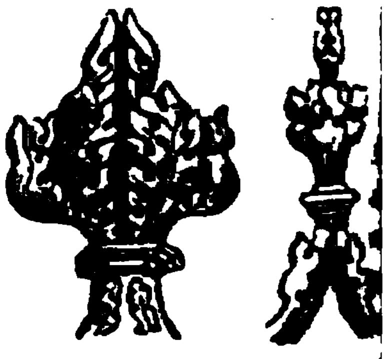
Fenestral. A frame, or "chassis," on which oiled paper or thin cloth was ained to keep out wind and rain when the windows were not glazed.

Festoon. An ornament of carved work, representing a wreath or garland of flowers or leaves, or both, interwoven with each other. It is thickest in the middle, and small at each extremity, where it is tied, a part often hanging down below the knot.

FESTOON

Fillet. A narrow vertical band or listel of frequent use in congeries of moldings, to separate and combine them, and also to give breadth and firmness to the upper edge of a crowning cyma or cavetto, as in an external cornice. The narrow slips or breadth between the flutes of Corinthian and Ionic columns are also called fillets. In mediæval work the fillet is a small, flat, projecting square, chiefly used to separate hollows and rounds, and often found in the outer parts of shafts and boutels. In this situation the center fillet has been termed a keel, and the two side ones, wings, but, apparently, this is not an ancient usage.

Finial. The flower, or bunch of flowers, with which a spire, pinnacle, gable, canopy, etc., generally terminates. Where there are crockets, the finial generally bears as close a resemblance as possible to them in point of design. They are found in early work where there are no crockets. The simplest form more resembles a bud about to burst than an open flower. They soon became more elaborate, as at Lincoln, and still more, as at Westminster and the Hôtel Cluny at Paris. Many perpendicular finials are like four crockets bound together. Almost every known example of a finial has a sort of necking separating it from the parts below



FINIALS

Fish-joint. A splice where the pieces are joined butt end to end, and are connected by pieces of wood or iron placed on each side and firmly bolted to the timbers, or pieces joined.

Flags. Flat stones, from 1 to 3 inches thick, for floors.

Flamboyant. A name applied to the Third Pointed style in France, which seems to have been developed from the Second, as the English Perpendicular was from the Decorated. The great characteristic is, that the element of the tracery flows upward in long wavy divisions like flames of fire. In most cases, also, every division has only one cusp on each side, however long the division may be. The moldings seem to be as much inferior to those of the preceding period as the Perpendicular moldings were to the Early English, a fact which seems to show that the decadence of Gothic architecture was not confined to one country.

Flange. A projecting edge, rib, or rim. Flanges are often cast on the top or bottom of iron columns, to fasten them to those above or below; the top and bottom of I-beams and channels are called the flange.

Flashings. Pieces of lead, tin, or copper, let into the joints of a wall so as to lap over gutters or other pieces; also, pieces worked in the slates or shingles around dormers, chimneys, and any rising part, to prevent leaking.

Flatting. Painting finished without leaving a gloss on the surface.

Flèche. A general term in French architecture for a spire, but more particularly used for the small, slender erection rising from the intersection of the nave and transepts in cathedrals and large churches, and carrying the sanctus bell.

Fleur-de-lis. The royal insignia of France, much used in decoration.

light. A run of steps or stairs from one landing to anotner.

loating. The equal spreading of plaster or stucco on the surface of walls, means of a board called a float; as a rule, only rough plastering is floated.

loriated. Having florid ornaments, as in Gothic pillars.

lue. The space or passage in a chimney through which the smoke ascends. ch passage is called a flue, while all together make the chimney.

lush. The continued surface, in the same plane, of two contiguous masses.

lute. A concave channel. Columns whose shafts are channeled are said be fluted, and the flutes are collectively called Flutings.

lying Buttress. An arched buttress used when extra strength was required the upper part of the wall of the nave, etc., to resist the outward thrust of a ulted ceiling. The flying buttress generally rests on the wall and buttress of aisle.

oils. The small arcs in the tracery of Gothic windows, panels, etc.

oliage. An ornamental distribution of leaves on various parts of buildings.

oliation. The use of small arcs or foils in forming tracery.

ont. The vessel used in the rite of baptism. The earliest extant is supposed be that in which Constantine is said to have been baptized; this is a porphyry rum from a Roman bath. Those in the baptisteries in Italy are all large, and re intended for immersion; as time went on, they seem to have become aller. Fonts are sometimes mere plain hollow cylinders, generally a little aller below than above; others are massive squares, supported on a thick stem, nd which sometimes there are smaller shafts. In the Early English this form still pursued, and the shafts are detached; sometimes, however, they are hex- onal and octagonal, and in this and the later styles assume the form of a vessel a stem. Norman fonts frequently have curious carvings on them, approach- the grotesque; in later times the foliages, etc., partook absolutely of the aracter of those used in other architectural details of their respective periods. e font in European churches is usually placed close to a pillar near the en- ance, generally that nearest but one to the tower in the south arcade; or, in ge buildings, in the middle of the nave, opposite the entrance porch, and netimes in a separate building. In Protestant churches in this country, the t is generally placed inside the communion rail, or on the steps of the chancel.

Footings. The spreading courses at the base or foundation of a wall. When ayer of different material from that of the wall (as a bed of concrete) is used, is called the Footing.

Foundation. That part of a building or wall which is below the surface of e ground.

Foxtail Wedging. Is a peculiar mode of mortising, in which the end of the on is notched beyond the mortise, and is split and a wedge inserted, which, ing forcibly driven in, enlarges the tenon and renders the joint firm and im- ovable.

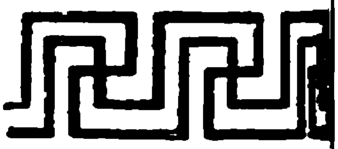
Frame. The name given to the wood-work of windows, doors, etc.; and in rpentry, to the timber works supporting floors, roofs, etc.

Framing. The rough timber work of a house, including the flooring, roofing, rtitioning, ceiling, and beams thereof.

Freestone. Stone which can be used for moldings, tracery, and other work quired to be executed with the chisel. The oölitic and sandstones are those nerally included by this term.

Fresco. The method of painting on a wall while the plastering is wet. color penetrates through the material, which, therefore, will bear rubbing or ing to almost any extent. The transparency, the chiaro-oscuro, and lucidity well as force, which can be obtained by this method, cannot be conceived the frescos of Fra Angelico or Raphael are studied. The word, however, is applied improperly to painting on the surface in distemper or body color, with size or white of egg, which gives an opaque effect.

Fret. An ornament consisting of small fillets intersecting each other at right angles.



FRET

Frieze. That portion of an entablature between the cornice above and architrave below. It derives its name from being the recipient of the sculptured enrichments either of foliage or figures which may be relevant to the object of the sculpture. The frieze is also called the Zoopho

Frigidarium. An apartment in the Roman bath, supplied with cold water

Furniture. A name given to the metal trimmings of doors, windows, other similar parts of a house. In this country the word "hardware" is generally used to denote the same thing.

Furrings. Flat pieces of timber used to bring an irregular framing to an surface.

Gable. When a roof is not hipped or returned on itself at the ends, its are stopped by carrying up the walls under them in the triangular form of roof itself. This is called the gable, or, in the case of the ornamental and mented gable, the pediment. Of necessity, gables follow the angles of the of the roof, and differ in the various styles. In Norman work they are gener about half-pitch; in Early English, seldom less than equilateral, and often In Decorated work they become lower, and still more so in the Perpendicul style. In all important buildings they are finished with copings or parapets. the Later Gothic styles gables are often surmounted with battlements, or enrich with crockets; they are also often paneled or perforated, sometimes very rich The gables in ecclesiastical buildings are mostly terminated with a cross; others, by a finial or pinnacle. In later times the parapets or copings were brok into a sort of steps, called corbic steps. In buildings of less pretension the or other roof covering passed over the front of the wall, which then, of cour had no coping. In this case, the outer pair of rafters were concealed by mold or carved verge boards.

Gable Window. A term sometimes applied to the large window under a gab but more properly to the windows in the gable itself.

Gabled Towers. Those which are finished with gables instead of parapet Many of the German Romanesque towers are gabled.

Gablets. Triangular terminations to buttresses, much in use in the Ea English and Decorated periods, after which the buttresses generally terminate pinnacles. The Early English gablets are generally plain, and very sharp pitch. In the Decorated period they are often enriched with paneling and crockets. They are sometimes finished with small crosses, but oftener with finials.

Gain. A beveled shoulder on the end of a mortised brace, for the purpose giving additional resistance to the shoulder.

Gallery. Any long passage looking down into another part of a building into the court outside. In like manner, any stage erected to carry a rood or organ, or to receive spectators, was latterly called a gallery, though originally

. In later times the name was given to any very long rooms, particularly se intended for purposes of state, or for the exhibition of pictures.

ambrel Roof. A roof with two pitches, similar to a mansard or curb roof.

argoyle, or Gurgoyle. The carved termination spout which conveyed away the water from the ters, supposed to be called so from the gurgling e made by the water passing through it. Gar- les are mostly grotesque figures.

ate-house. A building forming the entrance to own, the door of an abbey, or the enceinte of a le or other important edifice. They generally had rge gateway protected by a gate, and also a port- is, over which were battlemented parapets with s (machicolations) for throwing down darts, melted l, or hot sand on the besiegers. Gate-houses ays had a lodge, with apartments for the porter, . guard-rooms for the soldiers; and, generally, ms over for the officers, and often places for prisoners beneath. The name is r commonly applied to the gate-keeper's lodge on large estates.

GARGOYLE

auge. To mix plaster of Paris with common plaster to make it set quick, ed gauged mortar. A tool used by carpenters, to strike a line parallel to the e of a board.

irder. A large timber or iron beam, either single or built up, used to sup- t joists or walls over an opening.

lyph. A vertical channel in a frieze.

othic Style. The name of Gothic was given to the various Mediæval styles a period in the sixteenth century when a great classic revival was going on, l everything not classic was considered barbarian, or Gothic. The term was s originally intended as one of stigma, and, although it conveys a false idea of character of the Mediæval styles, it has long been used to distinguish them m the Grecian and Roman. The true principle of Gothic architecture is the tical division, relation and subordination of the different parts, distinct and at unity with each other, and while this principle was adhered to, Gothic hitecture may be said to have retained its vitality.

range. A word derived from the French, signifying a large barn or granary. anges were usually long buildings with high wooden roofs, sometimes divided posts or columns into a sort of nave and aisles, with walls strongly buttressed. England the term was applied not only to the barns, but to the whole of the ldings which formed the detached farms belonging to the monasteries; in st cases there was a chapel either included among these or standing apart as a arate edifice.

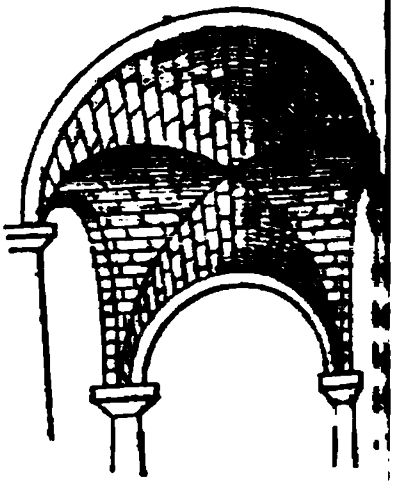
rillage. A framework of beams laid longitudinally and crossed by similar ms notched upon them, used to sustain walls to prevent irregular settling.

rille. The iron-work forming the enclosure screen to a chapel, or the pro- ting railing to a tomb or shrine; more commonly found in France than in gland. They are of wrought iron, ornamented by the swage and punch, and t together either by rivets or clips. In modern times grilles are used exten- ely for protecting the lower windows in city houses, also the glass opening in tside doors.

roin. By some described as the line of intersection of two vaults where they et each other, which others call the groin point; by others the curved section

or spandrel of such vaulting is called a groin, and by others the whole syst vaulting is so named.

Groin Arch. The cross-rib in the later styles of groining, passing at right angles from wall to wall, and dividing the vault into bays or travees.



GROINED VAULTING

Groin Ceiling. A ceiling to a building composed of oak ribs, the spandrels of which are filled in with narrow, thin slips of wood. There are several in England; one at the Early English church at Warmington, and one at Winchester Cathedral, exactly resembling those of stone.

Groin Centring. In groining without ribs, the whole surface is supported by centring during the erection of the vaulting. In ribbed work the stone ribs only are supported by timber ribs during the progress of the work, any light stuff being used while filling in the spand

Groin Point. The name given by workmen to the arris or line of intersecti of one vault with another where there are no ribs.

Groin Rib. The rib which conceals the groin point or joints, where the sp drels intersect.

Groined Vaulting. The system of covering a building with stone va which cross and intersect each other, as opposed to the barrel vaulting, or ser of arches placed side by side. The earliest groins are plain, without any ri except occasionally a sort of wide band from wall to wall, to strengthen the con struction. In later Norman times ribs were added on the line of intersection the spandrels, crossing each other, and having a boss as a key common to bo these ribs the French authors call *nerfs en ogive*. Their introduction, howev caused an entire change in the system of vaulting; instead of arches of unif thickness and great weight, these ribs were first put up as the main constructi and spandrels of the lightest and thinnest possible material placed upon them, haunches only being loaded sufficiently to counterbalance the pressure from crown. Shortly after, half-ribs against the walls (formerets) were introduced carry the spandrels without cutting into the walling, and to add to the appeara The work was now not treated as continued vaulting, but as divided into ba and it was formed by keeping up the ogive, or intersecting ribs and their bos a sort of construction having some affinity to the dome was formed, which ad much to the strength of the groining. Of course, the top of the soffit or ridge the vault was not horizontal, but rose from the level of the top of the formerets to the boss and fell again; but this could not be perceived from below. As t system of construction got more into use, and as the vaults were required to be greater span and of higher pitch, the spandrels became larger, and required m support. To give this, another set of ribs was introduced, passing from springers of the ogive ribs, and going to about half-way between these and ogive, and meeting on the ridge of the vault; these intermediate ribs are ca by the French *tiercerons*, and began to come into use in the transition from E English to Decorated. About the same period a system of vaulting came i use called *hexpartite*, from the fact that every bay is divided into six comp ments instead of four. It was invented to cover the naves of churches of unu width. The filling of the spandrels in this style is very peculiar, and, wher different compartments meet at the ridge, some pieces of harder stone ha been used, which give rather a pleasing effect. The arches against the wa being of smaller span than the main arches, cause the centre springers to be

dicular and parallel for some height, and the spandrels themselves are very ow. As styles progressed, and the desire for greater richness increased, ther series of ribs, called *liernes*, was introduced; these passed crossways from *ogives* to the *tiercerons*, and thence to the *doubleaux*, dividing the spandrels rly horizontally. These various systems increased in the Perpendicular od, so that the walls were quite a net-work of ribs, and led at last to the lor, or, as it is called by many, fan-tracery vaulting. In this system the ribs no part of the real construction, but are merely carved upon the voussoirs, ch form the actual vaulting. Fan Tracery is so called because the ribs iate from the springers, and spread out like the sticks of a fan. These later hods are not strictly groins, for the pendentives are not square on plan, but ular, and there is, therefore, no arris intersection or groin point.

roins, Welsh, or **Underpitch.** When the main longitudinal vault of any ning is higher than the cross or transverse vaults which run from the windows, system of vaulting is called underpitch groining, or, as termed by the workn, Welsh groining. A very fine example is at St. George's Chapel, Windsor, gland.

roove. In joinery, a term used to signify a sunk channel whose section is angular. It is usually employed on the edge of a molding, stile, or rail, , into which a tongue corresponding to its section, and in the substance of wood to which it is joined, is inserted.

rotesque. A singular and fantastic style of ornament found in ancient ldings.

rotto. An artificial cavern.

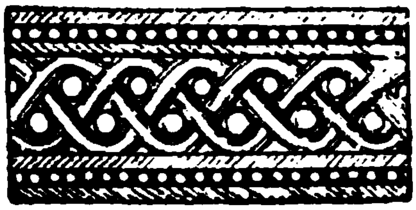
round Floor. The floor of a building on a level, or nearly so, with the und.

round Joist. Joist that is blocked up from the ground.

rounds. Pieces of wood embedded in the plastering of walls to which ting and other joiner's work is attached. They are also used to stop the tering around door and window openings.

rouped Columns. Three, four, or more columns put together on the same estal. When two are placed together, they are said to be coupled.

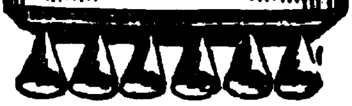
rout. Mortar made so thin by the addition of er that it will run into all the joints and cavities he mason-work, and fill it up solid.



GUILLOCHE

uilloche, or Guillochos. An interlaced ornat like net-work, used most frequently to enrich torus.

uttæ. The small cylindrical drops used to en- the mutules and regulæ of the Doric entabla- are so called.



GUTTÆ

utter. The channel for carrying off rain-water. mediæval gutters differed little from others, except t they are often hollows sunk in the top of stone nices, in which case they are generally called chan- in English, and *cheneaux* in French.

ymnasium. A building classed in the first rank by the Greeks; it was in m they instructed the youth in all the arts of peace and war; a building for letic exercises.

Hall. The principal apartment in the large dwellings of the Mi used for the purposes of receptions, feasts, etc. In the Norman cas was generally in the keep above the ground floor, where the retainer basement being devoted to stores and dungeons for confining prison halls — indeed, some Norman halls (not in castles) — are generally on floor, as at Westminster, approached by a porch either at the end, as example, or at the side, as at Guildhall, London, having at one end a or estrade. The roofs are generally open and more or less ornament middle of these was an opening to let out the smoke, though in later halls have large chimney-places with funnels or chimney-shafts for th At this period there were usually two deeply recessed bay windows of the dais, and doors leading into the withdrawing-rooms, or the b ments; they are also generally wainscoted with oak, in small panels, to of five or six feet, the panels often being enriched. Westminster originally divided into three parts, like a nave and side aisles, as are Continent of Europe. A room or passage-way at the entrance of a suite of chambers. A place of public assembly, as a town-hall, a m

Halving. The junction of two pieces of timber, by letting one into

Hammer Beam. A beam in a Gothic roof, not extending to th side; a beam at the foot of a rafter.

Hanging Buttress. A buttress not rising from the ground, but sup a corbel, applied chiefly as a decoration and used only in the Deco Perpendicular style.

Hanging Stile. Of a door, is that to which the hinges are fixed.

Hangings. Tapestry; originally invented to hide the coarseness of of a chamber. Different materials were employed for this purpose, them exceedingly costly and beautifully worked in figures, gold and s

Hatching. Drawing parallel lines close together for the purpose o ing a section of anything. The lines are generally drawn at an angle of a horizontal.

Haunches. The sides of an arch, about half-way from the springing crown.

Headers. In masonry, are stones or bricks extending over the thickness of a wall. In carpentry, the large beam into which the common joists are framed in framing openings for stairs, chimneys, etc.

Heading Courses. Courses of a wall in which the stone or brick are all headers.

Head-way. Clear space or height under an arch, or over a stairway, and the like.

Heel. Of a rafter, the end or foot that rests upon the wall plate.

Height. Of an arch, a line drawn from the middle of the chord to the intrados.

Helix. A small volute or twist like a stalk, representing the twisted tops of the acanthus, placed under the abacus of the Corinthian capital.

Hermes. A rough quadrangular stone or pillar, having a head, usually of Hermes or Mercury, sculptured on the top, without arms or body, placed by the Greeks in front of buildings.

HERMES

ing-bone Work. Bricks, tile, or other materials arranged diagonally ling.

astyle. A portico of six columns in front is of this description.

Altar. The principal altar in a cathedral or church. Where there is a it is generally at the end of the choir or chancel, not in the lady chapel.

knob. The finial on the hip of a roof, or between the barge boards of a

roof. A roof which rises by equally inclined planes from all four sides building.

podrome. A place appropriated by the ancients for equestrian exercises.

s. Those pieces of timber placed in an inclined position at the corners or of a hip-roof.

d-mold. A word used to signify the drip-stone for label over a window r opening, whether inside or out.

el de Ville. The town-hall, or guild-hall, in France, Germany, and ern Italy. The building, in general, serves for the administration of justice, ceipt of town dues, the regulation of markets, the residence of magistrates, ks for police, prisons, and all other fiscal purposes. As may be imagined, liffer very much in different towns, but they have almost invariably ed to them, or closely adjacent, a large clock-tower containing one or bells, for calling the people together on special occasions.

tel Dieu. The name for a hospital in mediæval times. In England there it few remains of these buildings, one of which is at Dover; in France there any. The most celebrated is the one at Angers, described by Parker. do not seem to differ much in arrangement of plan from those in modern the accommodation for the chaplain, medicine, nurses, stores, etc., being the same in all ages, except that in some of the earlier, instead of the sick placed in long wards like galleries, as is now done, they occupied large ings, with naves and side aisles, like churches.

using. The space taken out of one solid to admit the insertion of another. ase on a stair is generally housed into the treads and risers; a niche for a e.

pæthros. A temple open to the air, or uncovered. The term may be the easily understood by supposing the roof removed from over the nave of a h in which columns or piers go up from the floor to the ceiling, leaving the still covered.

pogea. Constructions under the surface of the earth, or in the sides of a r mountain.

nography. A horizontal section of a building or other object, showing its dimensions according to a geometric scale, a ground plan.

pluvium. The central part of an ancient Roman court, which was unred.

post. A term in classic architecture for the horizontal moldings of piers ilasters, from the top of which spring the archivolts or moldings which go d the arch.

Antis. When there are two columns between the antæ of the lateral walls the cella.

cise. To cut in; to carve; to engrave.

dented. Toothed together.

Inlaying. Inserting pieces of ivory, metal, or choice woods, or the like, in a groundwork of some other material, for ornamentation.

Insulated. Detached from another building. A church is insulated, when not contiguous to any other edifice. A column is said to be insulated, when standing free from the wall; thus, the columns of peripteral temples were insulated.

Intaglio. A sculpture or carving in which the figures are sunk below the general surface, such as a seal the impression of which in wax is in bas-relief; opposed to Cameo.

Intercolumniation. The distance from column to column, the clear space between columns.

Interlaced Arches. Arches where one passes over two openings, and they consequently cut or intersect each other.

Intrados. Of an arch, the inner or concave curve of the arch stones.

Inverted Arches. Those whose key-stone or brick is the lowest in the arch.

Ionic Order. One of the orders of Classical architecture.

Iron Work. In mediæval architecture, as an ornament, is chiefly confined to the hinges, etc., of doors and of church chests, etc. In some instances not only do the hinges become a mass of scroll work, but the surface of the doors is covered by similar ornaments. In almost all styles the smaller and less important doors had merely plain strap hinges, terminating in a few bent scrolls, and latterly in fleurs-de-lis. Escutcheon and ring handles, and the other furniture, partake more or less of the character of the time. On the Continent of Europe the knockers are very elaborate. At all periods doors have been ornamented with nails having projecting heads, sometimes square, sometimes polygonal, and sometimes ornamented with roses, etc. The iron work of windows is generally plain and the ornament confined to simple fleur-de-lis heads to the stanchions. The iron work of screens enclosing tombs and chapels is noticed under *Grille*, q.v.

Jack. An instrument for raising heavy loads, either by a crank, screw and pinion, or by hydraulic power, and in all cases worked by hand.

Jack Rafter. A short rafter, used especially in hip-roofs.

Jamb. The side-post or lining of a doorway or other aperture. The jambs of a window outside the frame are called Reveals.

Jamb-shafts. Small shafts to doors and windows with caps and bases; when in the inside arris of the jamb of a window they are sometimes called Escoinsons.

Joggle. A joint between two bodies so constructed by means of jogs or notches as to prevent their sliding past each other.

Joinery. That branch in building confined to the nicer and more ornamental parts of carpentry.

Joist. A small timber to which the boards of a floor or the laths of ceilings are nailed. It rests on the wall or on girders.

Keep. The inmost and strongest part of a mediæval castle, answering to the citadel of modern times. The arrangement is said to have originated with Gundulf, the celebrated Bishop of Rochester. The Norman keep is generally a very massive square tower, the basement or stories partly below ground being used for stores and prisons. The main story is generally a great deal above ground level, with a projecting entrance, approached by a flight of steps and drawbridge. This floor is generally supposed to have been the guard-room or place for the soldiery; above this was the hall, which generally extended over the whole area of the building, and is sometimes separated by columns; above this are other apartments for the residents. There are winding staircases in the angles of

uildings, and passages and small chambers in the thickness of the walls. The eep was intended for the last refuge, in case the outworks were scaled and the ther buildings stormed. There is generally a well in a mediæval keep, ingenusly concealed in the thickness of a wall, or in a pillar. The most celebrated f Norman times are the White Tower in London, the castles at Rochester, rundel, and Newcastle, Castle Hedingham, etc. The keep was often circular.

Key-stone. The stone placed in the center of the top of an arch. The charcter of the key-stone varies in different orders. In the Tuscan and Doric it is nly a simple stone projecting beyond the rest; in the Ionic it is adorned with oldings in the manner of a console; in the Corinthian and Composite it is a ch-sculptured console.

King-post. The middle post of a trussed piece of framing for supporting the e-beam at the middle and the lower ends of the struts.

Knee. A piece of timber naturally or artificially bent to receive another to lieve a weight or strain.

Knob, Knot. The bunch of flowers carved on a corbel, or on a Boss.

Kremlin. The Russian name for the citadel of a town or city.

Label. Gothic: the drip or hood-molding of an arch, when it is returned to e square.

Label Terminations. Carvings on which the labels terminate near the pringing of the windows. In Norman times those were frequently grotesque eads of fish, birds, etc., and sometimes stiff foliage. In the Early English and ecorated periods they are often elegant knots of flowers, or heads of kings, ueens, bishops, and other persons supposed to be the founders of churches. In e Perpendicular period they are often finished with a short square, mitred return knee, and the foliages are generally leaves of square or octagonal form.

Lacunar. A paneled or coffered ceiling or soffit. The panels or cassoons of ceiling are by Vitruvius called lacunaria.

Lady-chapel. A small chapel dedicated to the irgin Mary, generally found in ancient cathedrals.

Lancet. A high and narrow window pointed like lancet, often called a lancet window.

Landing. A platform in a flight of stairs between o stories; the terminating of a stair.

LACUNARS IN CEILING

Lantern. A turret raised above a roof or tower d very much pierced, the better to transmit light. modern practice this term is generally applied to y raised part in a roof or ceiling containing vertical ndows, but covered in horizontally. The name was also often applied to the uver or femerell on a roof to carry off the smoke; sometimes, too, to the open nstructions at the top of towers, as at Ely Cathedral, probably because lights re placed in them at night to serve as beacons.

Lanterns of the Dead. Curious small slender towers, found chiefly in the ntre and west of France, having apertures at the top, where a light was expited at night to mark the place of a cemetery. Some have supposed that the and towers in Ireland may have served for this purpose.

Lath. A slip of wood used in slating, tiling, and plastering.

Lattice. Any work of wood or metal made by crossing laths, rods, or bars, d forming a net-work. A reticulated window, made of laths or slips of iron,

separated by glass windows, and only used where air rather than light is to be admitted, as in cellars and dairies.

Lavabo. The lavatory for washing hands, generally erected in cloisters of monasteries. A very curious one at Fontenay, surrounding a pillar, is given by Viollet-le-Duc. In general, it is a sort of trough, and in some places has an almry for towels, etc.

Lavatory. A place for washing the person.

Lean-to. A small building whose rafters pitch or lean against another building, or against a wall.

Lectern. The reading-desk in the choir of churches.

Ledge, or Ledgement. A projection from a plane, as slips on the side of window and door frames to keep them steady in their places.

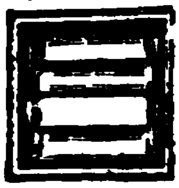
Ledgers. The horizontal pieces fastened to the standard poles or timbers of scaffolding raised around buildings during their erection. Those which rest on the ledgers are called putlogs, and on these the boards are laid.

Lewis. An iron clamp dovetailed into a large stone to lift it by.

Lich-gate. A covered gate at the entrance of a cemetery, under the shelter of which the mourners rested with the corpse, while the procession of the clergy came to meet them. There are several examples in England.

Light. A division or space in a sash for a single pane of glass; also a pane of glass.

Linen Scroll. An ornament formerly used for filling panels, and so called from its resemblance to the convolutions of a folded napkin.



LINEN SCROLL

Lining. Covering for the interior, as casing is covering for the exterior surface of a building; also, such as linings of a door for windows, shutters, and similar work.

Lintel. The horizontal piece which covers the opening of a door or window.

Lip Mold. A molding of the Perpendicular period like a hanging lip.

List, or Listel. A little square molding, to crown a larger; also termed a fillet.

Lithograph. A print from a drawing on stone.

Lobby. An open space surrounding a range of chambers, or seats in a theater; a small hall or waiting room.

Lodge. A small house in a park.

Loft. The highest room in a house, particularly if in the roof; also, a gallery raised up in a church to contain the rood, the organ, or singers.

Loggia. An outside gallery or portico above the ground, and contained within the building.

Loop-hole. An opening in the wall of a building, very narrow on the outside and splayed within, from which arrows or darts might be discharged on an enemy. They are often in the form of a cross, and generally have round holes at the ends.

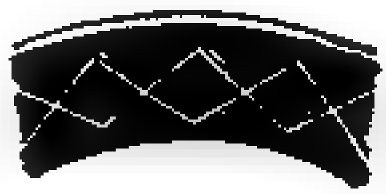
Lombard Architecture. A name given to the round-arched architecture of Italy, introduced by the conquering Goths and Ostrogoths, and which superseded the Romanesque. It reigned between the eighth and twelfth centuries during the time that the Saxon and Norman styles were in vogue in England, and corresponded with them in its development into the Continental Gothic.

Lotus. A plant of great celebrity amongst the ancients, the leaves and lossoms of which generally form the capitals of Egyptian columns.

Louver. A kind of vertical window, frequently in the peaks of gables, and in he top of towers, and provided with horizontal slats which ermit ventilation and exclude rain.

Lozenge Molding. A kind of molding used in Norman rchitecture, of many different forms, all of which are charcterized by lozenge-shaped ornaments.

Lunette. The French term or the circular opening in the roining of the lower stories of owers, through which the bells re drawn up.



LOZENGE MOLDING

LOUVER WINDOW

Machicolation. A parapet r gallery projecting from the upper part of the wall of a house or fortificaion, supported by brackets or corbels, and perforated in the lower part so that he defenders of the building might throw down darts, stones, and sometimes ot sand, molten lead, etc., upon their assailants below.

Man-hole. A hole through which a man may creep into a drain, cesspool, team-boiler, etc.

Manor-house. The residence of the suzerain or lord of the manor; in France e central tower or keep of a castle is often called the *manoir.*

Mansard Roof. Curb roof, invented by François Mansard, a distinguished rench architect, who died in 1666.

Mansion. A residence of considerable size and pretension.

Mantel. The work over a fireplace in front of a chimney; especially, a shelf, sually ornamented, above the fireplace.

Marquetry. Inlaid work of fine hard pieces of wood f different colors, also of shells, ivory, and the like.

Mausoleum. A magnificent tomb or sumptuous sepulhral monument.

Medallion. Any circular tablet on which are embossed gures or busts.

MACHICOLATION

Mediæval Architecture. The architecture of England, France, Germany, etc., during the Middle Ages, including the Norman and arly Gothic styles. It comprises also the Romanesque, Byzantine and Saraenic, Lombard, and other styles.

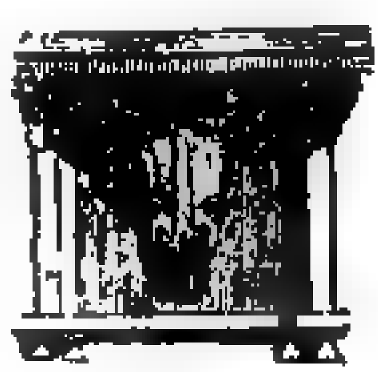
Members. The different parts of a building, the different parts of an entabtture, the different moldings of a cornice, etc.

Merlon. That part of a parapet which lies between wo embrasures.

Metope. The square recess between the triglypus in Doric frieze. It is sometimes occupied by sculptures.

Mezzanine. A low *story* between two lofty ones. t is called by the French *entresol*, or inter-story.

Mezzo-rilievo. Or mean relief, in comparison with lto-rilievo, or high relief.

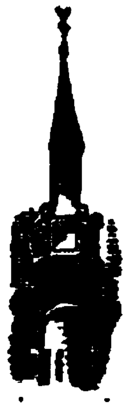


METOPE

Minaret. Turkish: a circular turret rising by different stages or divisions, each of which has a balcony.

Minster. Probably a corruption of monasterium — the large church attached to any ecclesiastical fraternity. If the latter be presided over by a bishop, it is generally called a Cathedral; if by an abbot, an Abbey; if by a prior, a Priory.

Minute. The sixtieth part of the lower diameter of a column; it is the measure used by architects to determine the proportions of an order.



MINARET

Miserere. A seat in a stall of a large church made to turn up and afford support to a person in a position between sitting and standing. The under side is generally carved with some ornament, and very often with grotesque figures and caricatures of different persons.

Miter. A molding returned upon itself at right angles is said to miter. In joinery, the ends of any two pieces of wood of corresponding form, cut off at 45°, necessarily abut upon one another so as to form a right angle, and are said to miter.

Modillion. So called because of its arrangement in regulated distances; the enriched block or horizontal bracket generally found under the cornice of the Corinthian entablature. Less ornamented, it is sometimes used in the Ionic.

MODILLION

Module. This is a term which has been generally used by architects in determining the relative proportions of the various parts of a columnar ordinance. The semi-diameter of the column at its base is the module, which being divided into thirty parts called minutes, any part of the composition is said to be of so many modules and minutes, or minutes alone, in height, breadth, or projection. The whole diameter is now generally preferred as a module, it being a better rule of proportion than its half.

Monastery. A set of buildings adapted for the reception of any of the various orders of monks, the different parts of which are described in the separate article, *Abbey*.

Monotriglyph. The intercolumniations of the Doric order are determined by the number of triglyphs which intervene, instead of the number of diameters of the column, as in other cases; and this term designates the ordinary intercolumniation of one triglyph.

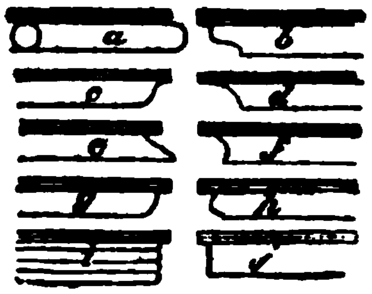
Monument. A name given to a tomb, particularly to those fine structures recessed in the walls of mediæval churches.

Mosaic. Pictorial representations, or ornaments, formed of small pieces of stone, marble, or enamel of various colors. In Roman houses the floors are often entirely of mosaic, the pieces being cubical. The best examples of mosaic work are found in St. Mark's, at Venice.

Mosque. A Mahometan temple, or place of worship.

Molding. When any work is wrought into long regular channels or projections, forming curves or rounds, hollows, etc., it is said to be molded, and each separate member is called a molding. In mediæval architecture the principal moldings are those of the arches, doors, windows, piers, etc. In the Early English style, the moldings, for some time, formed groups set back in square, and frequently very deeply undercut. The scroll molding is also common

all fillets now become very frequent in the keel molding, from its resemblance ection to the bottom of a ship; sometimes, also, it has a peculiar hollow on h side, like two wings. Later in the Decorated le the moldings are more varied in design, though lows and rounds still prevail. The undercutting is so deep, fillets abound, ogees are more frequent, the wave mold, double ogee, or double ressaunt, is n seen. In many places the strings and labels are und, the lower half of which is cut off by a plain mfer. The moldings in the later styles in some ree resemble those of the Decorated, flattened and nded; they run more into one another, having er fillets, and being, as it were, less grouped. of the principal features of the change is the stitution of one, or perhaps two (seldom more), large hollows in the set of moldings. These hol- s are neither circular nor elliptical, but obovate, an egg cut across, so that one half is larger the other. The brace mold also has a small l, where the two ogees meet. Another sort of ding, which has been called a lip mold, is common in parapets, bases, and therings.



MOLDINGS

a, astragal; *b*, ogee; *c*, cymatium; *d*, cavetto; *e*, scotia, or casement; *f*, apophyges; *g*, ovolo, or quarter round; *h*, torus; *i*, reeding; *j*, band.

Ioldings, Ornamented. The Saxon and early Norman moldings do not n to have been much enriched, but the complete and later styles of Norman remarkable for a profusion of ornamentation, the most usual of which is t is called the zigzag. This seems to be to Norman architecture what the nder or fret was to the Grecian; but it was probably derived from the ons, as it is very frequently found in their pottery. Bezants, quatrefoils, ages, crescents, billets, heads of nails, are very common ornaments. Besides e, battlements, cables; large ropes round which smaller ropes are turned, or, ur sailors say, "wormed"; scallops, pellets, chains, a sort of conical barrels, nt stiff foliages, beaks of birds, heads of fishes, ornaments of almost every con- ible kind, are sculptured in Norman moldings; and they are used in such usion as has been attempted in nc other style. The decorations on Early ish moldings are chiefly the dog-tooth, which is one of the great charac- tics of this style, though it is to be found in the Transition Norman. It is rally placed in a deep hollow between two projecting moldings, the dark ow in the hollow contrasting in a very beautiful way with the light in these ings. In this period and in the next the tympanum over doorways, par- urly if they are double doors, is highly ornamented. Those of the Decorated d resemble the former, except that the foliage is more natural and the dog- gives way to the ball-flower. Some of the hollows, also, are ornamented rosettes set at intervals, which are sometimes connected by a running tendril, e ball-flowers are frequently. Some very pleasing leaf-like ornaments in the s of windows are often found in Continental architecture. In the Perpen- ar period the moldings are ornamented very frequently by square four- d flowers set at intervals, but the two characteristic ornaments of the time unning patterns of vine leaves, tendrils, and grapes in the hollows, which d writers are called "vignettes in casements," and upright stiff leaves, ally called the Tudor leaf. On the Continent moldings partook much of ame character.

illion, Munion. The perpendicular pieces of stone, sometimes like col- , sometimes like slender piers, which divide the bays or lights of windows

o · screen-work from each other. In all styles, in less important work, the m lions are often simply plain chamfered, and more commonly have a very fla low on each side. In larger buildings there is often a bead or boutell on the and often a single very small column with a capital. As tracery grew richer, windows were divided by a larger order of mullion, between which came a l or subordinate set of mullions, which ran into each other. The term is applied to a wood or iron division between two windows.

Multifoil. A leaf ornament consisting of more than five divisions, applied foils in windows.

Mutule. The rectangular impending block under the corona of the Do cornice, from which guttæ or drops depend. Mutule is equivalent to modil but the latter term is applied more particularly to enriched blocks or bracke such as those of Ionic and Corinthian entablatures.

Narthex. The long arcaded porch forming the entrance into the Christi basilica. Sometimes there was an inner narthex, or lobby, before entering t church. When this was the case, the former was called exo-narthex, and t latter eso-narthex. In the Byzantine churches this inner narthex forms part the solid structure of the church, being marked off by a wall or row of colum whereas in the Latin churches it was usually formed only by a wooden or ot temporary screen.

Natural Beds. In stratified rocks, the surface of a stone as it lies in t quarry. If not laid in walls in their natural bed the laminæ separate.

Nave. The central part between the arches of a church, which formerly w separated from a chancel or choir by a screen. It is so called from its fanci resemblance to a ship. In the nave were generally placed the pulpit and fo In continental Europe it often also contains a high altar, but this is of ra occurrence in England.

Necking. The annulet or round, or series of horizontal moldings, whi separate the capital of a column from the plain part or shaft.

Newel. In mediæval architecture, the circular ends of a winding stairca which stand over each other, and form a sort of cylindrical column.

Newel Post. The post, plain or ornamented, placed at the first, or la step, to receive or start the hand-rail upon.

Niche. A recess sunk in a wall, generally for the reception of a sta Niches sometimes terminate by a simple label, but more commonly by a can and with a bracket or corbel for the figure, in which case they are often ca tabernacles.

Norman Style. Was that species of Romanesque which was practised by t Normans, and which was introduced and fully developed in England after th had established themselves in it. The chief features of this style are pla and massiveness. The arches, windows, and doorways were semicircular. pillars were very massive, and often built up of small stones laid like brick

Nosings. The rounded and projecting edges of the treads of a stair, or edge of a landing.

Obelisk. Lofty pillars of stone, of a rectangular form, diminishing towa top, and generally ornamented with inscriptions and hieroglyphics amo ancient Egyptians.

Observatory. A building erected on an elevated spot of ground for ma astronomical observations.

Octostyle. A portico of eight columns in front.

)ffsets. When the face of a wall is not one continued surface, but sets in by izontal jogs, as the wall grows higher and thinner, the jogs are called offsets.

)gee. The name applied to a molding, partly a hollow and partly a round, derived no doubt from its resemblance to an O placed over a G. It is rarely ıd in Norman work, and is not very common in Early English. It is of fre-nt use in Decorated work, where it becomes sometimes double, and is called a /e molding; and later still, two waves are connected with a small bead, which hen called a brace molding. In ancient MSS. it is called a Ressaunt.

)rchestra. In ancient theaters, where the chorus used to dance; in modern ıters, where the musicians sit.

)rder. A column with its entablature and stylobate is so called. The term is result of the dogmatic laws deduced from the writings of Vitruvius, and has ı exclusively applied to those arrangements which they were thought to rant.

)riel Window. Gothic: a projecting angular window, commonly of a tri-ıal or pentagonal form, and divided by mullions and transoms into different s and compartments.

)rthography. A geometrical elevation of a building or other object in which represented as it actually exists or may exist, and not perspectively, or as it ıld appear.

)rthostyle. A columnar arrangement in which the columns are placed in a ight line.

)volo. Same as *Echinus*.

'agoda. A name given to temples in India and China.

'alace. The dwelling of a king, prince, or bishop.

'ale. A fence picket, sharpened at the upper end.

'ane. Probably a diminutive of panneau, a term applied to the different es of glass in a window; same as *Light*.

'anel. Properly a piece of wood framed within four other pieces of wood, as he styles and rails of a door, filling up the aperture, but often applied both to whole square frame and the sinking itself; also to the ranges of sunken com-ments in wainscoting, cornices, corbel tables, groined vaults, ceilings, etc.

antograph, or **Pentagraph.** An instrument for copying on the same, or an rged or reduced scale.

antry. An apartment or closet in which bread and other provisions are t.

apier-maché. A hard substance made of a pulp from rags or paper mixed ı size or glue, and molded into any desired shape. Much used for architec-l ornaments.

arapet. A dwarf wall along the edge of a roof, or round a terrace walk, etc., revent persons from falling over, and as a protection to the defenders in case siege. Parapets are either plain, embattled, perforated, or paneled. The two are found in all styles except the Norman. Plain parapets are simply ions of the wall generally overhanging a little, with coping at the top and el table below. Embattled parapets are sometimes paneled, but oftener ed for the discharge of arrows, etc. Perforated parapets are pierced in ous devices — as circles, trefoils, quatrefoils, and other designs — so that the is seen through. Paneled parapets are those ornamented by a series of ls, eitner oblong or square, and more or less enriched, but are not perforated. e are common in the Decorated and Perpendicular periods.

Pargeting. A species of plastering decorated by impressing patterns when wet. These seem generally to have been made by sticking a number of pins in a board in certain lines or curves, and then pressing on the wet plaster in various directions, so as to form geometrical figures. Sometimes these devices are in relief, and in the time of Elizabeth represent figures, birds, foliage, etc. Rough plastering, commonly adopted for the interior surface of chimneys.

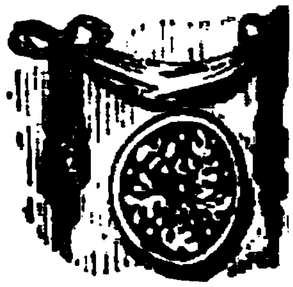
Parlor. A room in a house which the family usually occupy for society and conversation, and for receiving visitors. The apartment in a monastery or nunnery where the inmates are permitted to meet and converse with each other, or with visitors and friends from without.

Parochial. Belonging or relating to a parish.

Parquetry, or **Marquetry.** A kind of inlaid floor composed of small pieces of wood either square or triangular, which are capable of forming, by their position, various combinations of figures; this description of joinery is very suitable for the floors of libraries, halls, and public apartments.

Party Walls. Partitions of brick or stone between buildings on two adjoining properties.

Patera. A circular ornament resembling a dish, often worked in relief on friezes, etc.



PATERA

Pavement. Tessellated, a pavement of mosaic work, used by the ancients, made of square pieces of stone, etc., called Tessera.

Pavilion. A turret or small insulated building, and comprised beneath a single roof; also, the projecting part in front of a building which marks the centre, and which sometimes flanks a corner, when it is termed an angular pavilion.

Pedestal. The square support of a column, statue, etc.; and the base or lower part of an order of columns: it consists of a plinth for a base, the die, and a talon crowned for a cornice. When the height and width are equal, it is termed a square pedestal; one which supports two columns a double pedestal; and if it supports a row of columns without any break, it is a continued pedestal.

Pediment. A low triangular crowning, ornamented, in front of a building and over doors and windows. Pediments are sometimes made in the form of a segment; the space enclosed within the triangle is called the tympanum. Also the gable ends of classic buildings, where the horizontal cornice is carried across the front, forming a triangle with the end of the roof.

Pendent. A name given to an elongated boss, either molded or foliated, such as hang down from the intersection of groins, especially in fan tracery, or at the end of hammer beams. Sometimes long corbels, under the wall pieces, have been so called. The name has also been given to the large masses depending from enriched ceilings, in the later works of the Pointed style.

Pendent Posts. A name given to those timbers which hang down the side of a wall from the plate in hammer beam trusses, and which receive the hammer braces.

Pendentive. A name given to an arch which cuts off, as it were, the corners of a square building internally, so that the superstructure may become an octagon or a dome. In mediæval architecture these arches, when under a spire in the interior of a tower, are called Squinches.

Pendentive Bracketing, or Cove Bracketing. Springing from the rec-ngular walls of an apartment upward to the ceiling, and forming the horizon-l part of the ceiling into a circle or ellipse.

Pentastyle. Having five columns in front.

Pent-roof. A roof with a slope on one side only.

Perch. A measure used in measuring stone work, being 24¾ cu ft and 16½ ft, according to locality and custom.

Periptery. An edifice or temple surrounded by a peristyle.

Peristyle. A range of columns encircling an edifice, such as that which sur-unds the cylindrical drum under the cupola of St. Paul's. The columns of a eek peripteral temple form a peristyle also, the former being a circular, and e latter a quadrilateral peristyle.

Perpendicular Style. The third and last of the Pointed or Gothic styles; o called the Florid style.

Perspective Drawing. The art of making such a representation of an object on a plane surface as shall present precisely the same appearance that the ject itself would to the eye situated at a particular point.

Pews. A word of uncertain origin, signifying fixed seats in churches, com-sed of wood framing, mostly with ornamented ends. They seem to have come to general use early in the reign of Henry VI, and to have been rented and rell paid for" before the Reformation. Some bench ends are certainly of a corated character, and some have been considered to be of the Early English riod. They are sometimes of plain oak board, two and a half to three inches ick, chamfered, and with a necking and finial, generally called a poppy head; hers are plainly paneled with bold cappings; in others the panels are orna-nted with tracery or with the linen pattern, and sometimes with running iages. The divisions are filled in with thin chamfered boarding, sometimes ching to the floor, and sometimes only from the capping to the seat.

Picket. A narrow board, often pointed, used in making fences; a pale or ling.

Pier-glass. A mirror hanging between windows.

Piers. The solid parts of a wall between windows, and between voids gener-y. The term is also applied to masses of brick-work or masonry which are ulated to form supports to gates or to carry arches, posts, girders, etc.

Pilasters. Are flat square columns, attached to a wall, behind a column, or ng the side of a building, and projecting from the wall about a fourth or a th part of their breadth. The Greeks had a slightly different design for the pitals of pilasters, and made them the same width at top as at bottom, but the mans gave them the same capitals as the columns, and made them of di-nished width at the top, similar to the columns.

Pile. A large stake or trunk of a tree, driven into soft ground, as at the ttom of a river, or in made land, for the support of a building. (See p. 188.)

Pillar, or Pyller. A word generally used to express the round or polygonal rs, or those surrounded with clustered columns, which carry the main arches a building. Saxon and Early Norman pillars are generally stout cylindrical ifts built up of small stones. Sometimes, however, they are quite square, netimes with other squares breaking out of them (this is more common in nch and German work), sometimes with angular shafts, and sometimes they plain octagons. In Romanesque Norman work the pillar is sometimes iare, with two or more semicircular or half-columns attached. In the Early

English period the pillars become loftier and lighter, and in most important buildings are a series of clustered columns, frequently of marble, placed side by side, sometimes set at intervals round a circular centre, and sometimes almost touching each other. These shafts are often wholly detached from the central pillar, though grouped round it, in which case they are almost always of Purbeck or Bethersden marbles. In Decorated work the shafts on plan are very often placed round a square set anglewise, or a lozenge, the long way down the nave; the centre or core itself is often worked into hollows or other moldings, to show between the shafts, and to form part of the composition. In this and the latter part of the previous style there is generally a fillet on the outer part of the shaft, forming what has been called a keel molding. They are also often, as it were, tied together by bands formed of rings of stone and sometimes of metal. The small pillars at the jambs of doors and windows, and in arcades, and also those slender columns attached to pillars, or standing detached, are generally called shafts.

Pin. A cylindrical piece of wood, iron, or steel, used to hold two or more pieces together, by passing through a hole in each of them, as in a mortise and tenon joint, or a pin joint of a truss.

Pinnacle. An ornament originally forming the cap or crown of a buttress or small turret, but afterwards used on parapets at the corners of towers and in many other situations. It was a weight to counteract the thrust of the groining of roofs, particularly where there were flying buttresses; it stopped the tendency to slip of the stone copings of the gables, and counterpoised the thrust of spires; it formed the piers to steady the elegant perforated parapets of later periods; and in France, especially, served to counterbalance the weight of overhanging corbel tables, huge gargoyles, etc. In the Early English period the smaller buttresses frequently finished with gablets, and the more important with pinnacles supported with clustered shafts. At this period the pinnacles were often supported on these shafts alone, and were open below; and in larger work in this and the subsequent periods they frequently form niches and contain statues. In France, pinnacles, like spires, seem to have been in use earlier than in England. There are small pinnacles at the angles of the tower in the Abbey of Saintes. At Roullet there are pinnacles in a similar position, each composed of four small shafts, with caps and bases surmounted with small pyramidal spires. In all these examples the towers have semicircular headed windows.

PINNACLE.

Pitch of a Roof. The proportion obtained by dividing the height by the span; thus, we speak of its being one-half, one-third, one-fourth. When the length of the rafters is equal to the breadth of the building it is denominated Gothic.

Pitching-piece. A horizontal timber, with one of its ends wedged into the wall at the top of a flight of stairs, to support the upper end of the rough string.

Place. An open piece of ground surrounded by buildings, generally decorated with a statue, column, or other ornament.

Plan. A horizontal geometrical section of the walls of a building; or indications, on a horizontal plane, of the relative positions of the walls and partitions with the various openings, such as windows and doors, recesses and projections, chimneys and chimney-breasts, columns, pilasters, etc. This term is often incorrectly used in the sense of Design.

Planceer. Is sometimes used in the same sense as soffit, but is more correctly plied to the soffit of the corona in a cornice.

Plastering. A mixture of lime, hair, and sand, to cover lath-work between nbers or rough walling, used from the earliest times, and very common in man work. In the Middle Ages, too, it was used not only in private, but in blic constructions. On the inside face of old rubble walls it was not only used purposes of cleanliness, rough work holding dirt and dust, but as a ground distemper painting (tempera, or, as it is often improperly called, fresco), a ecies of ornament often used in the Middle Ages. At St. Albans Abbey, Engd, the Norman work is plastered, and covered with lines imitating the joints stone. The same thing is found in English Perpendicular work. On the outle of rubble walls, and often of wood framing, it was used as roughcast; when namented in patterns outside, it is called pargeting.

Plate. The piece of timber in a building which supports the end of the ters.

Plinth. The square block at the base of a column or pedestal. In a wall, the m plinth is applied to the projecting base or water table, generally at the level the first floor.

Plumb. Perpendicular; that is, standing according to a plumb line, as, the st of a house or wall is plumb.

Plumbing. The lead and iron pipes and other apparatus employed in conying water, and for toilet purposes in a building; originally the art of casting d working in lead.

Ply. Used to denote the number of thicknesses of roofing paper, as three ply, r ply, etc.

Podium. A continued pedestal; a projection from a wall, forming a kind of llery.

Polytriglyph. An intercolumniation in the Doric order of more than two glyphs.

Poppy Heads. Probably from the French *poupès:* the finials or other ornants which terminate the tops of bench ends, either to pews or lls. They are sometimes small human heads, sometimes richly rved images, knots of foliage, or finials, and sometimes fleurs-lis simply cut out of the thickness of the bench end and chamed.

POPPY HEAD

Porch. A covered erection forming a shelter to the entrance or of a large building. The earliest known are the long arcaded rches in front of the early Christian basilicas, called Narthex. later times they assume two forms—one, the projecting erection vering the entrance at the west front of cathedrals, and divided to three or more doorways, etc.; and the other, a kind of covered ambers open at the ends, and having small windows at the sides a protection from rain.

Portal. A name given to the deeply recessed and richly decorated entrance ors to the cathedrals in Continental Europe.

Portcullis. A strong-framed grating of oak, the lower points shod with iron, d sometimes entirely made of metal, hung so as to slide up and down in grooves th counterbalances, and intended to protect the gateways of castles, etc.

Portico. An open space before the door or other entrance to any building, nted with columns. A portico is distinguished as prostyle or *in antis* accord-

ing as it projects from or recedes within the building, and is further designated by the number of columns its front may consist of.

Post. Square timbers set on end. The term is especially applied to those which support the corners of a building, and are framed into bressummers or crossbeams under the walls.

Posticum. A portico behind a temple.

Presbytery. A word applied to various parts of large churches in a very ambiguous way. Some consider it to be the choir itself; others, what is now named the sacrarium. Traditionally, however, it seems to be applied to the vacant space between the back of the high altar and the entrance to the lady-chapel, as at Lincoln and Chichester; in other words, the back- or retro-choir.

Priming. The laying on of the first shade of color, in oil paint, and generally consisting mostly of oil, to protect and fill the wood.

Priory. A monastic establishment, generally in connection with an abbey, and presided over by a prior, who was a subordinate to the abbot, and held much the same relation to that dignitary as a dean does to a bishop.

Profile. The outline; the contour of a part, or the parts composing an order, as of a base, cornice, etc.; also, the perpendicular section. It is in the just proportion of their profiles that the chief beauties of the different orders of architecture depend. The ancients were most careful of the profiles of their moldings.

Proscenium. The front part of the stage of ancient theaters, on which the actors performed.

Prostyle. A portico in which the columns project from the building to which it is attached.

Protractor. A mathematical instrument for laying down and measuring angles on paper, used in drawing or plotting.

Pseudo-dipteral. False double-winged. When the inner row of columns of a dipteral arrangement is omitted and the space from the wall of the building to the columns is preserved, it is pseudo-dipteral.

Puddle. To settle loose dirt by turning on water, so as to render it firm and solid.

Pugging. A coarse kind of mortar laid on the boarding, between floor joists, to prevent the passage of sound; also called deafening.

Pulpit. A raised platform with enclosed front, whence sermons, homilies, etc., were delivered. Pulpits were probably derived in their modern form from the ambones in the early Christian church. There are many old pulpits of stone, though the majority are of wood. Those in the churches are generally hexagonal or octagonal; and some stand on stone bases, and others on slender wooden stems, like columns. The designs vary according to the periods in which they were erected, having paneling, tracery, cuspings, crockets, and other ornaments then in use. Some are extremely rich, and ornamented with color and gilding. A few also have fine canopies or sounding boards. Their usual place is in the nave, mostly on the north side, against the second pier from the chancel arch. Pulpits for addressing the people in the open air were common in the Medieval period, and stood near a road or cross. Thus, there was one at Spitalfields, and one at St. Paul's, London. External pulpits still remain at Magdalen College, Oxford, and at Shrewsbury, England.

Purlins. Those pieces of timbers which support the rafters to prevent them from sinking.

Putlog. Horizontal pieces for supporting the floor of a scaffold, one end being serted into putlog holes, left for that purpose in the masonry.

Putty in Plastering. Lump lime slacked with water to the consistency of eam, and then left to harden by evaporation till it becomes like soft putty. It then mixed with plaster of Paris, or sand, for the finishing coat.

Puzzolana. A grayish earth used for building under water.

Pyramid. A solid, having one of its sides, called a base, a plane figure, and ne other sides triangles, these points joining in one point at the top, called the ertex. Pyramids are called triangular, square, etc., according to the form of eir bases.

Pyx. In Roman Catholic churches, the box in which the host, or consecrated afer, is kept.

Quadrangle. A square or quadrangular court surrounded by buildings, as as often done formerly in monasteries, colleges, etc.

Quarry. A pane of glass cut in a diamond or lozenge form.

Quarry-face. Ashlar as it comes from the quarry, squared off for the joints nly, with split face. In distinction from Rock-face, in that the latter may be eather-worn, while Quarry-face should be fresh split. The terms are often sed indiscriminately.

Quatrefoil. Any small panel or perforation in the form of a four-leaved flower. ometimes used alone, sometimes in circles and over the aisle windows, but more requently in square panels. They are generally cusped, and the cusps are often eathered.

Queen Truss. A truss framed with two vertical tie-posts, in distinction from he king-post, which has but one. The upright ties are called Queen-posts.

Quirk Moldings. The convex part of Grecian moldings when they recede at he top, forming a reëntrant angle, with the surface which covers the moldings.

Quoins. Large squared stones at the angles of buildings, buttresses, etc., enerally used to stop the rubble or rough stone work, and that the angles may e true and stronger. Saxon quoin stones are said to have been composed of ne long and one short stone alternately. Early quoins are generally roughly xed; in later times they had a draught tooled by the chisel round the outside dges, and later still were worked fine from the saw.

Rafters. The joist to which the roof boarding is nailed. *Principal rafters* are the upper timbers in a truss, having the same inclination as the common rafters.

Rail. A piece of timber or metal extending from one post to another, as in fences, balustrades, staircases, etc. In framing and paneling, the horizontal pieces are called rails, and the perpendicular, *stiles.*

Raking. Moldings whose arrises are inclined to the horizon.

Ramp. A concavity on the upper side of hand railings formed over risers, made by a sudden rise of the steps above. Any concave bend or slope in the cap or upper member of any piece of ascending or descending workmanship.

Rampant. A term applied to an arch whose abutments spring from an inclined plane.

Random Work. A term used by stone-masons for stones fitted together at random without any attempt at laying them in courses. *Random Coursed Work* is a like term applied to work coursed in horizontal beds, but the stones are of any height, and fitted to one another.

Range Work. Ashlar laid in horizontal courses; same as coursed ashlar.

Rebate. A groove on the edges of a board.

Recess. A depth of some inches in the thickness of a wall, as a niche, etc.

Refectory. The hall of a monastery, convent, etc., where the religious took their chief meals together. It much resembled the great halls of mansions, castles, etc., except that there frequently was a sort of ambo, approached by steps, from which to read the Legenda Sanctorum, etc., during meals.

Reglet. A flat, narrow molding, used to separate from each other the parts or members of compartments and panels, to form frets, knots, etc.

Renaissance (a new birth). A name given to the revival of Roman architecture which sprang into existence in Italy as early as the beginning of the fifteenth century, and reached its zenith in that country at the close of the century. There are several divisions of this style as developed in different localities: viz.,

The Florentine Renaissance, of which the Pitti Palace, by Brunelleschi, is one of the best examples.

The Venetian Renaissance, characterized by its elegance and richness.

The Roman Renaissance, which originated in Rome, under the architects known as Bronte, Vignola, and Michael Angelo. Of this style the Farnese Palace, St. Peter's, and the modern Capitol at Rome are the best examples.

The French Renaissance, introduced into France in the latter part of the fifteenth century, by Italian architects, where it flourished until the middle of the seventeenth century. The Renaissance style was introduced into Germany about the middle of the sixteenth century, and into England about the same time by John of Padua, architect to Henry VIII. This style in England is generally known under the name of Elizabethan.

Rendering. In drawing, finishing a perspective drawing in ink or color, to bring out the spirit and effect of the design. The first coat of plaster on brick or stone work.

Reredos, Dorsal, or **Dossel.** The screen or other ornamental work at the back of an altar. In some large English cathedrals, as Winchester, Durham, St. Albans, etc., this is a mass of splendid tabernacle work, reaching nearly to the groining. In smaller churches there are sometimes ranges of arcades or panelings behind the altars; but, in general, the walls at the back and sides of them were of plain masonry, and adorned with hangings or paraments. In the large churches of Continental Europe the high altar usually stands under a sort of canopy or ciborium, and the sacrarium is hung round at the back and sides with curtains on movable rods.

Reticulated Work. That in which the courses are arranged in a form like the meshes of a net. The stones or bricks are square and placed lozenge-wise.

Return. The continuation of a molding, projection, etc., in an opposite direction.

Return Head. One that appears both on the face and edge of a work.

Reveal. The two vertical sides of an aperture, between the front of a wall and the window or door frame.

Rib. A molding or projecting piece upon the interior of a vault, or used to form tracery and the like. The earliest groining had no ribs. In early Norman times plain flat arches crossed each other, forming ogive ribs. These by degrees became narrower, had greater projection, and were chamfered. In later Norman work the ribs were often formed of a large roll placed upon the flat band, and then of two rolls side by side with a smaller roll or a fillet between them.

uch like the lower member. Sometimes they are enriched with zigzags and ther Norman decorations, and about this time bosses became of very general se. As styles progressed, the moldings were more undercut, richer, and more laborate, and had the dog-tooth or ball-flower or other characteristic ornament the hollows. In all instances the moldings are of similar contours to those f arches, etc., of the respective periods. Later, wooden roofs are often formed nto cants or polygonal barrel vaults, and in these the ribs are generally a cluster f rounds, and form square or stellar panels, with carved bosses or shields at the ntersections.

Ridge. The top of a roof which rises to an acute angle.

Ridge-pole. The highest horizontal timber in a roof, extending from top to op of the several pairs of rafters of the trusses, for supporting the heads of the ack rafters.

Rilievo, or Relief. The projection of an architectural ornament.

Rise. The distance through which anything rises, as the rise of a stair, or nclined plane.

Riser. The vertical board under the tread in stairs.

Rococo Style. A name given to that variety of the Renaissance which was in ogue during the seventeenth and the latter part of the sixteenth century.

Romanesque Style. The term Romanesque embraces all those styles of arhitecture which prevailed between the destruction of the Roman Empire and the eginning of Gothic architecture. In it are included the Early Roman Christian rchitecture, Byzantine, Mahometan, and the later Romanesque architecture roper, which was developed in Italy, France, England, and Germany. This ater Romanesque, which was quite different from the preceding, came into vogue luring the tenth century, and reached its height during the twelfth century, and n the thirteenth century gave way to the Pointed or Gothic style. In England, Romanesque architecture is known under the name of the Saxon, Norman, and Lombard styles, according to the different political periods.

Rood. A name applied to a crucifix, particularly to those which were placed n the rood-loft or chancel screens. These generally had not only the image of he crucified Saviour, but also those of St. John and the Virgin Mary standing ne on each side. Sometimes other saints and angels are by them, and the top of the screen is set with candlesticks or other decoration.

Rood-loft, Rood-screen, Rood-beam, Jube Gallery, etc. The arrangement to carry the crucifix or rood, and to screen off the chancel from the rest of the church during the breviary services, and as a place whence to read certain parts of those services. Sometimes the crucifix is carried simply on a strong transverse beam, with or without a low screen, with folding-doors below but forming no part of such support. In European churches the general construction of wooden screens is close paneling beneath, about 3 feet to 3 feet 6 inches high, on which stands screen work composed of slender turned balusters or regular wooden mullions, supporting tracery more or less rich, with cornices, cresting, etc., and often painted in brilliant colors and gilded. These not only enclose the chancels, but also chapels, chantries, and sometimes even tombs. In English mansions, and some private houses, the great halls were screened off by a low passage at the end opposite to the dais, over which was a gallery for the use of minstrels or spectators. These screens were sometimes close and sometimes glazed.

Rood-tower. A name given by some writers to the central tower, or that over the intersection of the nave and chancel with the transepts.

Roof. The covering or upper part of any building.

Roofing. The material put on a roof to make it water-tight.

Rose Window. A name given to a circular window with radiating tracery; called also wheel window.

Rostrum. An elevated platform from which a speaker addresses an audience.

Rotunda. A building which is round both within and without. A circular room under a dome in large buildings is also called the rotunda.

Roughcast. A sort of external plastering in which small sharp stones are mixed, and which, when wet, is forcibly thrown or cast from a trowel against the wall, to which it forms a coating of pleasing appearance. Roughcast work has been used in Europe for several centuries, where it was much used in timber houses, and when well executed the work is sound and durable. The mortar for roughcast work should always have cement mixed with it.

Rubble Work. Masonry of rough, undressed stones. When only the roughest irregularities are knocked off, it is called scabbled rubble, and when the stones in each course are rudely dressed to nearly a uniform height, ranged rubble.

Rudenture. The figure of a rope or staff, which is frequently used to fill up the flutings of columns, the convexity of which contrasts with the concavity of the flutings, and serves to strengthen the edges. Sometimes, instead of a convex shape, the flutings are filled with a flat surface; sometimes they are ornamentally carved, and sometimes on pilasters, etc. Rudentures are used in relief without flutings, as their use is to give greater solidity to the lower part of the shaft, and secure the edges. They are generally only used in columns which rise from the ground and are not to reach above one-third of the height of the shaft.

Rustic or **Rock Work.** A mode of building in imitation of nature. This term is applied to those courses of stone work the face of which is jagged or picked so as to present a rough surface. That work is also called rustic in which the horizontal and vertical channels are cut in the joinings of stones, so that when placed together an angular channel is formed at each joint. *Frosted rustic work* has the margins of the stones reduced to a plane parallel to the plane of the wall, the intermediate parts having an irregular surface. *Vermiculated rustic work* has these intermediate parts so worked as to have the appearance of having been eaten by worms. *Rustic chamfered work,* in which the face of the stones is smooth, and parallel to the face of the wall, and the angles beveled to an angle of one hundred and thirty-five degrees with the face so that two stones coming together on the wall, the beveling will form an internal right angle.

Sacristy. A small chamber attached to churches, where the chalices, vestments, books, etc., were kept by the officer called the sacristan. In the early Christian basilicas there were two semicircular recesses or apsides, one on each side of the altar. One of these served as a sacristy, and the other as the bibliotheca or library. Some have supposed the sacristy to have been the place where the vestments were kept, and the vestry that where the priests put them on; but we find from Durandus that the sacrarium was used for both these purposes. Sometimes the place where the altar stands enclosed by the rails has been called sacrarium.

Saddle Bars. Narrow horizontal iron bars passing from mullion to mullion, and often through the whole window, from side to side, to steady the stone work, and to form stays, to which the lead work is secured. When the bays of the windows are wide, the lead lights are further strengthened by upright bars passing through eyes forged on the saddle bars, and called stanchions. When

addle bars pass right through the mullions in one piece, and are secured to the ambs, they have sometimes been called stay bars.

Sagging. The bending of a body in the middle by its own weight, or the load upon it.

Salient. A projection.

Salon. A spacious and elegant apartment for the reception of company, or or state purposes, or for the reception of paintings, and usually extending hrough two stories of the house. It may be square, oblong, polygonal, or ircular.

Sanctuary. That part of a church where the altar is placed; also, the most acred or retired part of a temple. A place for divine worship; a church.

Sanctus Bell-cot, or **Turret.** A turret or enclosure to hold the small bell ounded at various parts of the service, particularly where the words "Sanctus," tc., are read. This differs but little from the common bell-cot, except that it is enerally on the top of the arch dividing the nave from the chancel. Sometimes, owever, the bell seems to have been placed in a cot outside the wall. In Engand sanctus bells have also been placed over the gables of porches. In Contiental Europe they run up into a sort of small slender spire, called *flèche* in rance, and *guglio* in Italy.

Saracenic Architecture. That Eastern style employed by the Saracens, and which distributed itself over the world with the religion of Mahomet. It is a nodification and combination of the various styles of the countries which they onquered.

Sarcophagus. A tomb or coffin made of stone, and intended to contain the ody.

Sash. The framework which holds the glass in a window.

Scabble. To dress off the rougher projections of stones for rubble masonry vith a stone axe or scabbling hammer.

Scagliola. An imitation of colored marbles in plaster work, made by a comination of gypsum, glue, isinglass, and coloring matter, and finished with a high olish, invented between 1600 and 1649.

Scantling. The dimensions of a piece of timber in breadth and thickness; lso, studding for a partition, when under five inches square.

Scarfing. The joining and bolting of two pieces of timber together transersely, so that the two appear as one.

Sconce. A fixed hanging or projecting candlestick.

Scotia. A concave molding, most commonly used in bases, which projects a leep shadow on itself, and is thereby a most effective molding under the eye, s in a base. It is like a reversed ovolo, or, rather, what the mold of an ovolo vould present.

Scratch Coat. The first coat of plaster, which is scratched to afford a bond or the second coat.

Screeds. Long narrow strips of plaster put on horizontally along a wall, and arefully faced out of wind, to serve as guides for plastering the wide intervals etween them.

Screen. Any construction subdividing one part of a building from another, s a choir, chantry, chapel, etc. The earliest screens are the low marble podia hutting off the chorus cantantium in the Roman basilicas, and the perforated ancelli enclosing the bema, altar, and seats of the bishops and presbyters. The chief screens in a church are those which enclose the choir or the place where

the breviary services are recited. In Continental Europe this is done not only by doors and screen work, but also, when these are of open work, by curtains, the laity having no part in these services. In England screens were of two kinds: one, of open wood-work, generally called rood-screens or jubes, and which the French call *grilles, clôtures du chœur;* the other, massive enclosures of stone work enriched with niches, tabernacles, canopies, pinnacles, statues, crestings, etc., as at Canterbury, York, Gloucester, and many other places.

Scribing. Fitting wood-work to an irregular surface.

Section. A drawing showing the internal heights of the various parts of a building. It supposes the building to be cut through entirely, so as to exhibit the walls, the heights of the internal doors and other apertures, the heights of the stories, thicknesses of the floors, etc. It is one of the species of drawings necessary to the exhibition of a Design.

Sedilia. Seats used by the celebrants during the pauses in the mass. They are generally three in number — for the priest, deacon, and sub-deacon — and are in England almost always a species of niches cut into the south wall of churches, separated by shafts or by a species of mullions, and crowned with canopies, pinnacles, and other enrichments more or less elaborate. The piscina and ambry sometimes are attached to them. In Continental Europe the sedilia are often movable seats; a single stone seat has rarely been found.

Set-off. The horizontal line shown where a wall is reduced in thickness, and, consequently, the part of the thicker portion appears projecting before the thinner. In plinths this is generally simply chamfered. In other parts of work the set-off is generally concealed by a projecting string. Where, as in parapets, the upper part projects before the lower, the break is generally hid by a corbel table. The portions of buttress caps which recede one behind another are also called set-offs.

Shaft. In Classical architecture that part of a column between the necking and the apophyge at the top of the base. In later times the term is applied to slender columns either standing alone or in connection with pillars, buttresses, jambs, vaulting, etc.

Shed Roof, or **Lean-to.** A roof with only one set of rafters, falling from a higher to a lower wall, like an aisle roof.

Shore. A piece of timber placed in an oblique direction to support a building or wall temporarily while it is being repaired or altered.

Shrine. A sort of ark or chest to hold relics. It is sometimes merely a small box, generally with a raised top like a roof; sometimes an actual model of churches; sometimes a large construction, like that of Edward the Confessor at Westminster, of St. Genevieve at Paris, etc. Many are covered with jewels in the richest way; that of San Carlo Borromeo, at Milan, is of beaten silver.

Sills. Are the timbers on the ground which support the posts and superstructure of a timber building. The term is most frequently applied to those pieces of timber or stone at the bottom of doors or windows.

Skewback. The inclined stone from which an arch springs.

Skirtings. The narrow boards which form a plinth around the margin of a floor, now generally called the base.

Sleeper. A piece of timber laid on the ground to receive floor joists.

Soffit. The lower horizontal face of anything as, for example, of an entablature resting on and lying open between the columns, or the under face of an arch where its thickness is seen.

ound Board. The covering of a pulpit to deflect the sound into a church.

all. Bad or broken brick; stone chips.

an. The distance between the supports of a beam, girder, arch, truss, etc.

andrel, or Spandril. The space between any arch or curved brace and the l label, beams, etc., over the same. The spandrels over doorways in Perpen-ilar works are generally richly decorated.

pecification. Architect's. The designation of the kind, quality, and ntity of work and material to go in a building, in conjunction with the working wings.

pire. A sharply pointed pyramid or large pinnacle, generally octagonal in gland, and forming a finish to the tops of towers. Timber spires are very nmon in England. Some are covered with lead in flat sheets, others with the ne metal in narrow strips laid diagonally. Very many are covered with ngles. In Continental Europe there are some elegant examples of spires of en timber work covered with lead.

Splayed. The jamb of a door, or anything else of which one side makes an lique angle with the other.

Springer. The stone from which an arch springs; in some cases this is a pital, or impost; in other cases the moldings continue down the pier. The west stone of the gable is sometimes called a springer.

Squinches. Small arches or corbeled set-offs running diagonally and, as it re, cutting off the corners of the interior of towers, to bring them from the uare to the octagon, etc., to carry the spire.

Squint. An oblique opening in the wall of a church; especially, in mediæval chitecture, an opening so placed as to afford a view of the high altar from the insept or aisles.

Staging. A structure of posts and boards for supporting workmen and aterial in building.

Stall. A fixed seat in the choir for the use of the clergy. In early Christian nes the thronus cathedra, or seat of the bishop, was in the center of the apsis bema behind the altar, and against the wall; those of the presbyters also were ainst the wall, branching off from side to side around the semicircle. In later nes the stalls occupied both sides of the choir, return seats being placed at the ds for the prior, dean, precentor, chancellor, or other officers. In general, in thedrals, each stall is surmounted by tabernacle work, and rich canopies, nerally of oak.

Stanchion. A word derived from the French *étançon*, a wooden post, applied the upright iron bars which pass through the eyes of the saddle bars or hori-ntal irons to steady the lead lights. The French call the latter *traverses*, the inchions *montants*, and the whole arrangement *armature*. Stanchions fre-iently finish with ornamental heads forged out of the iron.

Steeple. A general name for the whole arrangement of tower, belfry, spire, etc.

Stereobate. A basement, distinguished from the nearly equivalent term sty-bate by the absence of columns.

Stile. The upright piece in framing or paneling.

Stilted. Anything raised above its usual level. An arch is stilted when its ntre is raised above the line from which the arch appears to spring.

Stoop. A seat before the door; often a porch with a balustrade and seats on e sides.

Stoup. A basin for holy water at the entrance of Roman Catholic ch
Into which all who enter dip their fingers and cross themselves.

Straight Arch. A form of arch in which the intrados is straight, but w
joints radiating as in a common arch.

Strap. An iron plate for connecting two or more timbers, to which
screwed by bolts. It generally passes around one of the timbers.

Stretcher. A brick or block of masonry laid lengthwise of a wall.

String Board. A board placed next to the well-hole in wooden stairs, t
nating the ends of the steps. The string piece is the piece of board put
the treads and risers for a support, and forming the support of the stair.

String-course. A narrow, vertically faced and slightly projecting co
an elevation. If window-sills are made continuous, they form a string-c
but if this course is made thicker or deeper than ordinary window-sills, or c
a set-off in the wall, it becomes a blocking-course. Also, horizontal mold
running under windows, separating the walls from the plain part of the para
dividing towers into stories or stages, etc. Their section is much the sa
the labels of the respective periods; in fact, these last, after passing roun
windows, frequently run on horizontally and form strings. Like labels, the
often decorated with foliages, ball-flowers, etc.

Studs, or **Studding.** The small timbers used in partitions and outside wo
walls, to which the laths and boards are nailed.

Style. The term style in architecture has obtained a conventional mea
beyond its simpler one, which applies only to columns and columnar arra
ments. It is now used to signify the differences in the moldings, general
lines, ornaments, and other details which exist between the works of va
nations, and also those differences which are found to exist between the work
any nation at different times.

Stylobate. A basement to columns. Stylobate is synonymous with pedesta
but is applied to a continued and unbroken substructure or basement to column
while the latter term is confined to insulated supports. The Greek temples ge
erally had three or more steps all around the temple, the base of the colum
resting on the top step; this was the stylobate.

Subsellium. A name sometimes given to the seat in the stalls of churche
same as miserere.

Summer. A girder or main-beam of a floor; if supported on two-story pos
and open below, it is called a Brace-summer.

Surbase. A cornice or series of moldings on the top of the base of a pedesta
podium, etc.; a molding above the base.

Surface. To make plane and smooth.

Systyle. An intercolumniation to which two diameters are assigned.

Tabernacle. A species of niche or recess in which an image may be plac
They are generally highly ornamented and often surmounted with crocket
gables. The word tabernacle is also often used to denote the receptacle for rel
which was often made in the form of a small house or church.

Tabernacle Work. The rich ornamental tracery forming the canopy, e
to a tabernacle, is called tabernacle work; it is common in the stalls and scre
of cathedrals, and in them is generally open or pierced through.

Tail Trimmer. A trimmer next to the wall, into which the ends of joists a
fastened to avoid flues.

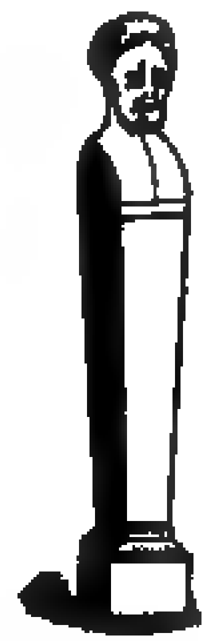
Tamp. To pound the earth down around a wall after it has been thrown in.

Tapestry. A kind of woven hangings of wool or silk, ornamented with figures, ıd used formerly to cover and adorn the walls of rooms. They were often of ɛ most costly materials and beautifully embroidered.

Temple. An edifice destined, in the earliest times, for the public exercise of ligious worship.

Templet, or **Template.** A mold used by masons for cutting or setting work. short piece of timber sometimes laid under a girder.

Terminal. Figures of which the upper parts only, or perhaps the head and oulders alone, are carved, the rest running into parallelopiped, and sometimes into a diminishing :destal, with feet indicated below, or even with- ıt them, are called terminal figures.



ANCIENT TERMINI

Terra-cotta. Baked clay of a fine quality. ıch used for bas-reliefs for adorning the friezes temples. In modern times employed for archi- ctural ornaments, statues, vases, etc.

Tessellated Pavements. Those formed of sseræ, or, as some write it, tesselle, or small ıbes from half an inch to an inch square, like ce, of pottery, stone, marble, enamel, etc.

Tetrastyle. A portico of four columns in front.

Tholobate. That on which a dome or cupola sts. This is a term not in general use, but it is not e less of useful application. What is generally rmed the attic above the peristyle and under the cupola of St. Paul's, London, ould be correctly designated the tholobate. A tholobate of a different descrip- ɔn, and one to which no other name can well be applied, is the circular sub- ructure to the cupola of the University College, London.

Throat. A channel or groove made on the under-side of a string-course, ping, etc., to prevent water from running inward toward the walls.

Tie. A timber, rod, chain, etc., binding two bodies together, which have a ndency to separate or diverge from each other. The *tie-beam* connects the ttom of a pair of principal rafters, and prevents them from bursting out the ıll.

Tiles. Flat pieces of clay burned in kilns, to cover roofs in place of slates or ıd. Also, flat pieces of burned clay, either plain or ornamented, glazed or ıglazed, used for floors, wainscoting, and about fireplaces, etc. Small square eces of marble are also called tile.

Tongue. The part of a board left projecting, to be inserted into a groove.

Tooth Ornament. One of the peculiar marks of the Early English period of othic architecture, generally inserted in the hollow moldings of doorways, ındows, etc.

Torso. A mutilated statue of which nothing remains but the trunk. Columns ıth twisted shafts have also this term. Of this kind there are several varieties.

Torus. A protuberance or swelling, a molding hose form is convex, and generally nearly approaches semicircle It is most frequently used in bases, and generally the lowest molding in a base.

TORUS

Tower. An elevated building originally designed for purposes of defense. Those buildings are of the remotest antiquity, and are, indeed, mentioned in the earliest Scriptures. In mediæval times they were generally attached to churches, to cemeteries, to castles, or used as bell-towers in public places of large cities. In churches, the towers of the Saxon period were generally square. Norman towers were also generally square. Many were entirely without buttresses; others had broad, flat, shallow projections which served for this purpose. The lower windows were very narrow, with extremely wide splays inside, probably intended to be defended by archers. The upper windows, like those of the preceding style, were generally separated into two lights, but by a shaft or short column, and not by a baluster. Early English towers were generally taller, and of more elegant proportions. They almost always had large projecting buttresses, and frequently stone staircases. The lower windows, as in the former style, were frequently mere arrow-slits; the upper were in couplets or triplets, and sometimes the tower top had an arcade all around. The spires were generally broach spires; but sometimes the tower tops finished with corbel courses and plain parapets, and (rarely) with pinnacles. There are a few Early English towers which break into the octagon from the square toward the top, and still fewer which finish with two gables. Both these methods of termination, however, are common in Continental Europe. At Vendôme, Chartres, and Senlis the towers have octagonal upper stages surrounded with pinnacles, from which elegant spires arise. In the North of Italy, and in Rome, they are generally tall square shafts in four to six stages, without buttresses, with couplets or triplets of semicircular windows in each stage, generally crenellated at top, and covered with a low pyramidal roof. The well-known leaning tower at Pisa is cylindrical, in five stories of arcaded colonnades. In Ireland there are in some of the churchyards very curious round towers.

Tracery. The ornamental filling in of the heads of windows, panels, circular windows, etc., which has given such characteristic beauty to the architecture of the fourteenth century. Like almost everything connected with mediæval architecture, this elegant and sometimes fairy-like decoration seems to have sprung from the smallest beginnings. The circular-headed window of the Normans gradually gave way to the narrow-pointed lancets of the Early English period, and, as less light was afforded by the latter system than by the former, it was necessary to have a greater number of windows; and it was found convenient to group them together in couplets, triplets, etc. When these couplets were assembled under one label, a sort of vacant space or spandrel was formed over the lancets and under the label. To relieve this, the first attempts were simply to perforate this flat spandrel, first by a simple lozenge-shaped or circular opening, and afterward by a quatrefoil. By piercing the whole of the vacant spaces in the window head, carrying moldings around the tracery, and adding cusps to it, the formation of tracery was complete, and its earliest result was the beautiful geometrical work such as is found at Westminster Abbey.

Transept. That portion of a church which passes transversely between the nave and choir at right angles, and so forms a cross on the plan.

Transom. The horizontal construction which divides a window into heights or stages. Transoms are sometimes simple pieces of mullions placed transversely as cross-bars, and in later times are richly decorated with cuspings, etc.

Traverse. To plane in a direction across the grain of the wood, as to traverse a floor by planing across the boards.

Tread. The horizontal part of a step of a stair.

Trefoil. A cusping the outline of which is derived from a three-leaved flower leaf, as the quatrefoil and cinque-foil are from those with four and five.

Trellis. Lattice-work of metal or wood for vines to run on.

Trestle. A movable frame or support for anything; when made of a cross ece with four legs it is called by carpenters a horse.

Triforium. The arcaded story between the lower range of piers and arches d the clere-story. The name has been supposed to be derived from *tres* and *es* — three doors, or openings — that being a frequent number of arches in ch bay.

Triglyph. The vertically channeled tablets of the Doric frieze are called glyphs, because of the three angular channels in them — two perfect and one vided — the two chamfered angles or hemiglyphs being reckoned as one. The uare sunk spaces between the triglyphs on a frieze are called metopes.

Trim. Of a door, sometimes used to denote the locks, knobs, and hinges.

Trimmer. The beam or floor joist into which a header is framed.

Trimmer Arch. An arch built in front of a fireplace, in the thickness of the or, between two trimmers. The bottom of the arch starting from the chimney d the top pressing against the header.

Tuck-pointing. Marking the joints of brickwork with a narrow parallel lge of fine putty.

Tudor Style. The architecture which prevailed in England during the reign the Tudors; its period is generally restricted to the end of the reign of Henry III.

Turret. A small tower, especially at the angles of larger buildings, sometimes erhanging and built on corbels, and sometimes rising from the ground.

Tuscan Order. The plainest of the five orders of Classic architecture.

Tympanum. The triangular recessed space enclosed by the cornice which ounds a pediment. The Greeks often placed sculptures representing subjects nnected with the purposes of the edifice in the tympana of temples, as at the arthenon and Ægina.

Under-croft. A vaulted chamber under ground.

Upset. To thicken, and shorten as by hammering a heated bar of iron on the id.

Vagina. The upper part of the shaft of a terminus, from which the bust or gure seems to rise.

Valley. The internal angle formed by two inclined sides of a roof.

Valley Rafters. Those which are disposed in the internal angle of a roof to orm the valleys.

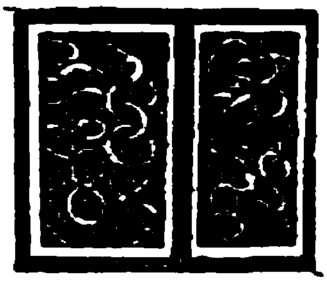
Vane. The weathercock on a steeple. In early times it seems to have been f various forms, as dragons, etc.; but in the Tudor period the favorite design as a beast or bird sitting on a slender pedestal, and carrying an upright rod, on hich a thin plate of metal is hung like a flag, ornamented in various ways.

Vault. An arched ceiling or roof. A vault is, indeed, a laterally conjoined eries of arches. The arch of a bridge is, strictly speaking, a vault. Intersecting aults are said to be groined. See *Groined Vaulting* for fuller description of aults.

Verge. The edge of the tiling, slate or shingles, projecting over the gable of a oof, that on the horizontal portion being called eaves.

Verge Board. Often corrupted into Barge Board; the board under the verge of gables, sometimes molded, and often very richly carved, perforated, and cusped, and frequently having pendants, and sometimes finials, at the apex.

Vermiculated. Stones, etc., worked so as to have the appearance of having been worked by worms.



VERMICULATED

Vestibule. An anti-hall, lobby, or porch.

Vestry. A room adjoining a church, where the vestments of the minister are kept and parish meetings held. In American Protestant churches, the Sunday-school room is often called the vestry.

Viaduct. A structure of considerable magnitude, and usually of masonry, for carrying a railway across a valley.

Vignette. A running ornament, representing, as its name imports, a little vine, with branches, leaves, and grapes. It is common in the Tudor period, and runs or roves in a large hollow or casement. It is also called Trayle.

Villa. A country house for the retreat of the rich.

Volute. The convolved or spiral ornament which forms the characteristic of the Ionic capital. Volute, scroll, helix, and cauliculus are used indifferently for the angular horns of the Corinthian capital.

Voussoir. One of the wedge-like stones which form an arch; the middle one is called the key-stone.

Wainscot. The wooden lining of walls, generally in panels.

Wall Plates. Pieces of timber which are placed on top of brick or stone walls so as to form the support to the roof of a building.

Warped. Twisted out of shape by seasoning.

Water Table. A slight projection of the lower masonry or brickwork on the outside of a wall a few feet above the ground as a protection against rain.

Weather Boarding. Boards lapped over each other to prevent rain, etc., from passing through.

Weathering. A slight fall on the top of cornices, window-sills, etc., to throw off the rain.

Wicket. A small door opening in a larger. They are common in mediæval doors, and were intended to admit single persons, and guard against sudden surprises.

Wind. A turn, a bend. A wall is *out of wind* when it is a perfectly flat surface.

Wing. A side building less than the main building.

Withes. The partition between two chimney flues in the same stack.

RCHITECTURAL TERMS AS DEFINED IN VARIOUS BUILDING LAWS

COMPILED BY THE AMERICAN ARCHITECT AND BUILDING NEWS, PAGE 150, VOL. XXXIII

(Republished by permission of Ticknor & Co.)

Terms Defined

[he following terms chance to be defined in sundry building codes, which are tioned in each case. The fact that other codes are not mentioned is not neces- ly a proof that the term is not also elsewhere in use as defined.]

djoining Owner. The owner of the premises adjoining those on which k is doing or to be done. [*District of Columbia.*]

lteration. Any change or addition except necessary repairs in, to, or upon building affecting an external, party, or partition wall, chimney, floor, or rway, and "to alter" means to make such change or addition. [*Boston and ver.*]

ppendages. Dormer-windows, cornices, moldings, bay-windows, towers, es, ventilators, etc. [*Chicago and Minneapolis.*]

reas. Sub-surface excavations adjacent to the building-line for lighting or tilation of cellars or basements. [*District of Columbia.*]

ttic Story. A story situated either in whole or in part in the roof. [*Denver District of Columbia.*]

ase. "The *base* of a brick wall" means the course immediately above the ndation wall. [*Cincinnati and Cleveland.*]

asement Story. One whose floor is 12″ or more below the sidewalk, and se height does not exceed 12′ in the clear; all such stories that exceed 12′ h shall be considered as first stories. [*Chicago and Louisville.*]

story whose floor is 12″ or more below the grade of sidewalk. [*Milwaukee.*]

story whose floor is 3′ or more below the sidewalk, and whose height does exceed 11′ in the clear; all such stories that exceed 11′ high shall be con- ered as first stories. [*Minneapolis.*]

story suitable for habitation, partially below the level of the adjoining street ground.* [*District of Columbia and Denver.*]

See **Cellar.**)

ay-window. A first-floor projection for a window other than a tower-pro- ion or show-window. [*District of Columbia.*]

ny projection for a window other than a show-window. [*Denver.*]

earing Walls. Those on which beams, trusses, or girders rest. [*New York San Francisco.*]

rick Building. A building the walls of which are built of brick, stone, iron, other substantial and incombustible materials. [*Boston, Denver, and Kansas y.*]

* And below the first floor of joists. [*District of Columbia.*]

Building. Any construction within the scope and purview of these r tions. [*District of Columbia.*]

Building Line. The line of demarcation between public and private [*District of Columbia.*]

Building Owner. The owner of premises on which work is doing or done. [*District of Columbia.*]

Business buildings shall embrace all buildings used principally for bu purposes, thus including, among others, hotels, theaters, and office-buil [*Chicago, Louisville, Milwaukee, and Minneapolis.*]
